Campaigns in East Prussia.—The battle of Tannenberg evealed his powers of generalship, for he there demonstrated he justice of the theory of annihilation. The victory of Tannenerg over the Russian Army of the Narew was more than another annae. For in this case there was not, as in former days on he Aufidus, merely one enemy to be dealt with. On the conary, the attempt was made to envelop the greatly superior ain body of Russians in the presence of a second enemy force reatening the rear. And the attempt proved successful. In e subsequent operations which led to the first battle on the asurian Lakes and to the heavy defeat of the Russian Army the Niemen, the enemy's right wing was supported on the ke, and so only an envelopment of the southern wing was ssible. The operations, therefore, took the form of an attack the enemy's front and on his exposed flank.

The strategic success lay in the liberation of East Prussia om the enemy. The German Army of the East became availle for the immediate support of the Austro-Hungarian ally, by is time in dire straits. This support was rendered in the brilnt Oct. campaign of the newly-formed IX. German Army rected through Southern Poland upon the Vistula. Its purse—to facilitate the Austrian efforts in Galicia by drawing upon the IX. Army the strongest possible body of Russian oops—was attained in a degree entailing grave danger to the tnumbered Germans themselves. The menace of envelopnt by a vastly superior enemy, pouring up from the direction Warsaw, was parried and beaten off by Ludendorff by means an exceedingly gallant defensive action, carried out during thdrawal. In Nov., after a rapid regrouping of the main Gern forces, an advance was made from the Wreschen-Thorn e against the right flank of the main body of the Russians, ng in West Poland. In the absence of sufficient strength a multaneous frontal attack was impossible. But even so, the ccess achieved in the battle of Lódź was great. The Russians re definitely relegated to the defensive—and, in the pursuit which followed, were flung back behind the Bzura and the Rawka.

During the fighting in Masuria in Feb. 1915 Ludendorff achieved the destruction of another Russian Army in the region of the Upper Bobr. This was followed by a period of relative inactivity on the German Eastern Front lasting for several months. Not before the middle of July 1915 did the army group of Hindenburg resume the war of movement. By an attack directed upon and beyond the Lower Narew it relieved, by means of a converging offensive, the army group of Mackensen which had advanced from Galicia into Southern Poland between the Vistula and the Bug. In the ensuing operations the Russian Army was driven out of the Vistula positions and out of the whole of Poland towards the East. After a brief resistance the fortresses of Warsaw, Nowogeorgiewsk (Modlin) and Kovno fell. But no decisive issue was reached, because General von Falkenhayn, Chief of the German General Staff, rejected the proposal of Hindenburg and Ludendorff, which was to advance with the German left wing in a northerly direction through Kovno and Vilna upon Minsk, thereby cutting the Russian railway communications, north of the Polesia. Had the operations been conducted in accordance with the views of Hindenburg and Ludendorff, the Russian Army might have been dealt a mortal blow in the summer of 1915. Later, in Sept., the attempt was made on the German left wing, but with inadequate forces, to embarrass the retreat of the section of the Russian Army withdrawing northwards from Polesia past Vilna; but the moment for success on a grand scale had gone.

After the victorious conclusion of the Balkan campaign in the winter of 1915-6 Ludendorff contemplated a great offensive into the heart of the Ukraine, with the object of breaking the back of the economic resistance of Greater Russia, which was already cut off from the sea. The offensive necessitated the occupation of Rumania; but General von Falkenhayn rejected this scheme, and chose Verdun instead of Kiev as the objective for operations. Accordingly in the year 1916 the Eastern Front of the allied Central Powers was assigned the duty of protecting the rear of the offensive movement in France. This task was amply fulfilled on the northern wing but on the southern wing, held by the Austrians, the front completely collapsed in June and July at Łuck and in Galicia. The balance in the East was restored with difficulty by the intervention of the German command.

On Aug. 29 Field-Marshal von Hindenburg assumed the office of Chief of the General Staff of the armies in the field, in the place of Falkenhayn, and Ludendorff became First Quartermaster General. In contrast with their predecessor's point of view, the two men still promised themselves triumph, but a triumph which could only result from a more vigorous conduct of the War by drawing upon the whole available strength of the country in wealth and population. The methods adopted for the utilisation of these resources were expressed in the so-called "Hindenburg programme" of war industries and in the so-called law of auxiliary services; and here Ludendorff could only co-operate by means of suggestions and demands. In his own sphere too, he found that, owing to the almost desperate military situation inherited from his predecessor, he was not at first able to put into practice Schlieffen's doctrine of annihilation. The result of the offensive against Rumania was that this new enemy was overthrown in the winter of 1916. This victory was of inestimable value to the Central Powers, for new sources of economic power were thereby opened up.

Submarine Warfare.—After the defeat of the Rumanian Army there remained but one further task. This was the frustration of the attacks of the enemy in the West, greatly superior in numbers and material. The restoration of the balance of strength thus aimed at was to enable the Central Powers later to deliver an offensive with decisive effect. A favourable diversion of this kind, however, could only be counted upon, if, during the strategical defence on land, England could be reduced to desperate straits. An intensified U-boat warfare in the blockade area round England was therefore adopted, a weapon, recourse to which had hitherto always been postponed on the score of political considerations. The disadvantage of this course was that it would give the United States a pretext for war on the side of the Entente; but regarding this as inevitable, Ludendorff hoped to render England disposed for peace before the Americans should be in a position to throw considerable forces into Europe.

---

[1] The department which draws up plans for transport, disposition troops and advance.

Unrestricted U-boat warfare did not altogether fulfil expectations. The technical perfection of the enemy's defensive weapons and the ample scale upon which they had been completed contributed to this in a very material degree. On the other hand, without the adoption of unrestricted U-boat warfare the strategy of the Central Powers would have been altogether unable to hold the balance on land in suspense until, after Russia's collapse in the spring of 1918, there dawned a well-founded prospect of forcing a decision in France before the American forces on land became effective.

In the spring of 1917 in the Western theatre of war Ludendorff was enabled, by a timely withdrawal to the Siegfried position and by the elasticity of his defensive tactics, to impose a check upon the Allied attack carried out with a gigantic expenditure of men and material. Subsequently he had another opportunity of vindicating his theory of annihilation in the warfare on land. Under the blows dealt by the German hammer at Tarnopol, Riga, Dagö and Ösel, Russia fell. The reckoning with Italy followed in the autumn of 1917, but the situation in the West, particularly in Flanders where the fighting raged with undiminished fury, rendered it impossible for Ludendorff to secure a decisive victory.

The Offensive of 1918.—The German resolution to take the offensive in the spring of 1918 was rendered imperative by the general position. The psychological condition of the army peremptorily demanded that the rôle of anvil should be exchanged for that of hammer. Conditions at home called for a potent remedy against the threefold poison instilled by the hunger blockade, enemy propaganda and revolutionary agitation. Germany's hard pressed allies had for long rested their sole hopes of delivery on the efforts of Germany. Ludendorff saw only one road by which a tolerable peace, in harmony with the honour of the German people, could be reached, the road of military victory. This again could be attained solely by means of an offensive which should be decisive, and in taking this course he hazarded everything. A series of small attacks with limited objectives or a powerfully conducted defence would in favourable circumstances only have secured a temporary advantage, but could not prevent the enemy from finally giving full effect to his superior strength in a battle of annihilation. It is questionable whether the choice of direction for the offensive on French territory can be defended. Many critics would have preferred an offensive in Italy, but apart from the natural difficulties, even the destruction of the Italian Army could at best only have preceded the main decisive operations on French soil.

It has been questioned whether Ludendorff assembled adequate forces for the spring offensive of 1918. In March, at the beginning of this offensive, the Germans disposed of 193 divisions and three brigades in the Franco-Belgian theatre of war. The estimates of the forces commanded by the Entente in France and Belgium at the beginning of the spring offensive vary between 167 and 180 divisions. The Germans, therefore, enjoyed a slight superiority in the number of divisions. The original intention that a section of the Austro-Hungarian forces should take part in the decisive encounter in France was finally thwarted by the opposition of the Habsburg Emperor. Ludendorff accordingly chose the expedient of indirect assistance to be rendered by a relieving offensive carried out by the Austro-Hungarian Army in Upper Italy. This offensive, however, was undertaken much too late for the objective in view, in the middle of June, and, moreover, ended with a severe reverse. The occupation of Rumania called imperatively for four divisions and a greater number of Landsturm formations. The invasion of the Ukraine, carried out in Feb. and March, demanded about 20 weak divisions, including eight divisions of Landwehr and three of cavalry. It is disputable whether it would have been wiser to abandon the enterprise in the Ukraine. The secretary of state of the *Kriegsernährungsamt* urged with the utmost emphasis tha the economic resources of the Ukraine should be thrown ope to Germany. Failing this, the Austrians' system of food supplie would collapse. The delivery of meat was important for Germany, too, and the delivery of horses was, above all, a matter o the greatest urgency.

On political and military grounds Ludendorff had resolved t deal the first decisive blow in the West against the English. Fo this purpose he chose the southern flank, on both sides of St Quentin, as tactically the least defensible, with the intention o forcing his way through at this point and by advancing nort of the Somme towards the northwest, to roll up the whole fron gradually and press the English towards the sea. The souther wing of the German offensive was to guard his flank against relieving attack on the part of the French. This strategy becam subject to certain changes in consequence of the unexpecte magnitude of the initial success of the German southern wing which continued the offensive across the Somme and the Croza canal against the French, in order to effect a cleavage betwee the English and French at and beyond Amiens. This end wa not completely attained, and the result of the first offensive though great from the tactical standpoint was strategicall nugatory. A second attack on the Lys front, against the Englis and Portuguese, was made in the middle of April and was designed to gain possession of the commanding heights north Bailleul and to cut off the Ypres salient; its result, however, wa indecisive.

During the following months, in spite of successive brillian diversive attacks carried out against the French front, no furthe headway was made in forcing a decisive engagement in Flanders and the heavy toll of the spring offensives could not be mad good rapidly enough. And yet, prior to the last great attemp to break through on both sides of Reims in July 1918, ther still remained a prospect of final victory for the German arms The goal had nearly been reached—which was a proof that th strategy adopted might have succeeded and was, therefore, th right strategy. But the fortune of war was against Ludendorf His plans were revealed by treachery to the enemy, at a tim when everything depended on secrecy and surprise. The grea successes hitherto achieved had led to a wide extension of th German front, calling for the employment of disproportionatel large forces and offering in its many angles and salients dangerou surfaces to the enemy's attacks. These factors now made thei disastrous influence felt.

But the final cause of Ludendorff's inability to resume th initiative lay in the absence of a free command of reserves, du to the drying up of the sources of supply at home. When th German command fell back on the defensive before hosti attacks, Ludendorff realised that there was nothing to be don except to hold out until diplomacy succeeded in securing a to erable peace, or to perish with honour. On Oct. 26, however, h was overthrown by the Cabinet of Prince Max of Baden. Th collapse of Germany's allies, combined with difficulties at hom rendered hopeless any further resistance by the army in the fiel now thrown upon its own resources.

General Ludendorff was above all a man of action, and on who rated formation of character and the attributes of leade ship more highly than the acquisition of comprehensive learnin His resolution, his almost super-human and invincible powers work and action, his understanding of the moral factors in wa fare, inspired the German Army with boundless confidence his leadership and qualified it for mighty exploits. If like Hannibal and Lee he failed in the final issue, it was through no faul in generalship, but was partly due to slowness in realising tha his weapon had grown blunt and that the population at hom was no longer capable of the effort of endurance and the indispensable will to victory. His powers of leadership reflected hi character; brain, heart and will were all unsparingly enlisted i the service of one aim, the honour of his country. Along thi path he was impelled to travel, whether it led to victory o defeat.

LUGARD, SIR FREDERICK JOHN DEALTRY (1858–), ritish administrator (*see* 17.115), was, on the completion of his erm of office as Governor of Hongkong, appointed in March 912 Governor of both Northern and Southern Nigeria, with nstructions to amalgamate the two administrations. The amalamation became effective on Jan. 1 1914, Sir Frederick being iven the personal title of governor-general. He guided the ffairs of Nigeria throughout the World War, retiring in 1919, nd was made a Privy Councillor in 1920. In 1922 he published *he Dual Mandate*, a book dealing with the duties of European owers in tropical Africa. In Nov. of that year he became a ember of the permanent mandates commission of the League f Nations (*see* MANDATES, NIGERIA).

LUKEMAN, HENRY AUGUSTUS (1871–), American ulptor, was born at Richmond, Va., Jan. 28 1871. He studied t the National Academy of Design, N.Y. City, and was a pupil f Launt Thompson and Daniel Chester French, perfecting his nowledge of anatomy by his year's study at Bellevue Hospital. n 1894 he spent a year in Paris studying under Falquière at the cole des Beaux-Arts, and on his return to the United States ettled in New York City. His work includes portraits, busts, tatues, memorials and bas-reliefs, among the best known being Mann, the Law Giver of India” for the Appellate Court uilding, New York City; the statue of President McKinley at dams, Mass.; “Genoa,” the figure of Columbus on the U.S. ustoms House, New York City (1905); The Soldiers' Monuent at Somerville, Mass. (1908); the group “Women of the onfederacy,” at Raleigh, N.C. (1912); the Soldiers' Memorial, ed Hook Park, Brooklyn, N.Y. (1920); the equestrian statue “Francis Asbury,” Washington, D.C. (1921). He was apointed in 1925 to succeed Gutzon Borglum as sculptor in arge of the Stone Mountain memorial near Atlanta, Georgia. *ee* ATLANTA.)

LUNACHARSKY, ANATOLY VASILIEVICH (1873–), ussian politician, author and dramatist, was born in the provce of Kiev of well-to-do parents. He joined the revolutionary ovement when still at college in Kiev, and afterwards studied tural science and economics at the University of Zurich. He egan his revolutionary activities in Russia in 1895 and was derted to Vologda in 1897, where he remained for three years, hieving a reputation as a brilliant writer and lecturer on Soalism. In 1903 Lunacharsky joined the Bolshevik or “majori” wing of the Social-Democratic party. He met Lenin in the llowing year, and also joined the editorial staff of the Bolshevik per *Vpered* (Forward). While doing literary work of a general ture he was chiefly concerned with social democratic propanda and with lectures and political meetings for Russian stunts and political refugees abroad. During the revolution of 05 Lunacharsky was imprisoned for his political activities, and hen the subsequent political reaction set in he left Russia and ent to live in Italy. Together with Gorky and Bogdanov, a ell-known Social Democrat, he formed the so-called “left-wing” Bolshevism (opposed to Lenin on certain theoretical points), d was one of the promoters of the Social Democratic party hools at Capri and Bologna.

From the outbreak of the World War Lunacharsky maintained determined internationalist attitude and disseminated violent ti-War propaganda in Paris and Switzerland, renewing closer ntact with the Lenin group after a temporary estrangement. the same time he made a careful study of educational probns in Switzerland, and this was to prove extremely useful to m later in his career. The revolution of March 1917 brought m back to Russia, and he immediately joined Lenin and Troty in their revolutionary opposition to the Provisional Governent. He was arrested after the Bolshevik rising in July; but s subsequently liberated and elected vice-president of the etrograd municipal board. In the initial stages of the Oct. volution and during the civil war, Lunacharsky proved himself one of the ablest political speakers of the new Soviet State, and was an energetic and successful emissary of the Military Revolutionary Council to the various war fronts. As people's Commissar for Public Instruction in the new Soviet Govt., Lunacharsky rendered inestimable services by ensuring the preservation of works of culture and art during the civil war. He devoted himself to the promotion of mass instruction, and of culture and art in Soviet Russia, while his especial concern for the welfare of the theatre did much to further the development of the Russian stage.

A man of exceptional culture, steeped in philosophical and scientific studies, Lunacharsky also won his spurs in the field of literature. He wrote 14 plays (published in 2 vol.), of which several were produced with conspicuous success in Russia and in Berlin. “Vasilisa the Wise,” “Faust and the City” and “The Magi” were translated into English by Leonard Magnus and published under the title of *Three Plays* (1923). He also wrote books on politics, economics, philosophy, literature and art.

LUND, TROELS FREDERIK (1840–1921), Danish historian (*see* 17.123), published in 1909 *Nye Tanker i det XVI. Aarhundreds*. In 1911–2 appeared his historical tales, *Tider og Tanker*. He died in 1921. See Knud Fabricius, *Troels Lund* (1921).

LUNG: *see* HEART AND LUNG SURGERY.

LUPU, NICHOLAS (1876–), Rumanian politician, was born at Arsura (Rumania) on Nov. 8 1876. He started his career as a country doctor and entered politics in 1905. He played an important part during the peasant revolt in 1907 when, as prefect of the Falciu district, he succeeded in pacifying the peasants without having recourse to violent measures. In 1913 he was elected deputy and in 1919 he entered the Vaida-Voevod Coalition Cabinet as minister of the interior, representing, together with Mihalache, the Peasant (Tsaranist) party, of which Dr. Lupu became one of the principal leaders. During the World War, Dr. Lupu visited Russia, France, England, Italy and the United States and carried on an active propaganda campaign on behalf of Rumania.

LUSCHAN, FELIX VON (1854–1924), Austrian anthropologist and ethnographer, was born on Aug. 11 1854 in Vienna. He studied medicine in Vienna, anthropology in Paris, became demonstrator in physiology at the university at Vienna, and in 1878 organised the Austro-Hungarian section for anthropology and ethnology at the World Exhibition in Paris. Whilst a military doctor in Bosnia, he studied anthropology and archaeology, and in 1880 travelled in Dalmatia, Montenegro and Albania. During the following 10 years he was often in Asia Minor and Egypt, and in 1883 excavated the ruins of Sendschirli in Northern Syria on behalf of the Berlin Oriental Committee. After a brief period as lecturer in anthropology in Vienna, he became directorial assistant at the Ethnological Museum in Berlin, of which he was director from 1904 until his death, on Feb. 7 1924. His works include: *Beiträge zur Völkerkunde der deutschen Schutzgebiete* (1897); *Die Ausgrabungen von Sendschirli*, 2 pts. (1893, 1898); *Beiträge zur Ethnographie von Neu-Guinea* (1899); *Beiträge zur Anthropologie von Kreta; Rassen und Völker* (1908); *Völker, Rassen und Sprachen* (1922); *Anthropological View of Race;* Papers on Inter-racial Problems communicated to the First Universal Race Congress (London, 1911); “The Early Inhabitants of Western Asia,” *Jour. Roy. Anth. Inst. of Great Britain and Ireland* (1911).

LUTHER, HANS (1879–), German statesman, was born in Berlin March 10 1879, and studied law in Berlin, Kiel and Geneva. After ending his studies he entered the local administration service. At first he was stationed in Charlottenburg, and from 1907–13, in the Magistrat in Magdeburg under the former minister of finance, Lenze. In 1913 he was elected secretary to the German and Prussian “Städtetag,” and thus was able during the World War to prove his high administrative abilities. On July 5 1918 he was elected burgomaster of Essen in the Ruhr district. In this responsible position he gained the reputation of being one of the best local administrative officials in the West of

Germany. On Dec. 2 1922 he entered the Cuno Cabinet, and became Minister of Food and Agriculture. He retained his post in Essen and, when the French marched into the Ruhr in Jan. 1923, he returned to Essen immediately. The episode is well-known of how the general commanding the troops marching into Essen wished to speak with the burgomaster at the door of the Rathaus (town hall). Dr. Luther sent a message that he was only to be seen in his office. The order was repeated twice, but at last the General was obliged to give way. This manly attitude of Dr. Luther earned him high esteem in the turbulent, warlike atmosphere in the Ruhr at that time.

After Cuno ceased to be Chancellor, Luther retained his office in the Stresemann Cabinet. In Stresemann's second Cabinet, he became Minister of Finance. As Finance Minister of the Reich, he was able to perform most signal services in stabilising the German currency (which had fallen into an abyss) and in restoring balance to the budget of the Reich. Dr. Luther kept his office in the Marx Ministry which followed, and had a share in the preparations for the Conference of London and the conclusion of the Dawes Agreement. In the autumn of 1924 he concluded the Dawes loan for Germany. He has himself given an account of his work in restoring the finances of Germany (see *Feste Mark—solide Wirtschaft, 1924*). After the elections in Dec. 1924, Marx, in spite of many endeavours, was not able to form a new cabinet, and Luther took over the task in the middle of Jan. 1925. A Cabinet was formed under him, which was the first since the revolution of 1918 to include members of the German National party. Luther carried through a great taxation reform, completed the revaluation legislation and made a provisional customs tariff which made it possible to commence negotiations for commercial agreements with some prospect of success for German economic life. This economic legislation was accompanied by the Locarno policy initiated by Stresemann with the essential agreement of Luther, who, as Chancellor, was responsible for the conduct of policy as a whole.

At the Conference of Locarno, the German delegation which initialled the clauses of the treaty, was led by Luther as Chancellor. After his return from Locarno, the German National party left the Government. In spite of this, the Cabinet found a majority for the policy of Locarno, and on Dec. 1 1925 signed the Rhine Pact and the Arbitration Treaties in London, after which it resigned. After tedious Government crises, Luther again received the mandate to form a Cabinet. As the Social Democrats forsook the Chancellor, there was nothing left but to form a Cabinet out of the moderate bourgeois parties. Dr. Luther was not a party politician, and often proclaimed his freedom from the parties in a pronounced fashion. While in charge of the affairs of the Reich he distinguished himself by extraordinary energy and sober clarity of political judgment, and the German people indubitably made important progress towards reconstruction under his leadership. On May 13 he resigned his office as chancellor. (*See* GERMANY.) (F. KLE.)

LUTHERANS (*see* 17.140).—The Lutheran churches of Europe were profoundly influenced by the War of 1914–8 and its aftereffects. The external changes were least marked in Sweden, Denmark and Norway, where the relation between the churches and their states has remained undisturbed; in Germany and the new national states they have been far-reaching.

I. IN THE OLD WORLD

German Lutherans.—The German revolution of 1918 put an end to the *Summepiskopat* (*see* 17.142) and the reorganisation of the German Empire aimed at the separation of Church and State. Since an immediate complete separation would be disastrous to the churches and not to the best interest of the state, the churches were guaranteed diminishing state support, with the ultimate purpose of divorcing them entirely from the state governments. By this arrangement the churches have, in part, the character of voluntary associations and, in part, that of state controlled institutions. To meet this new situation they have been obliged to reorganise. The forms of reorganisation have not been identical in all the states, but two tendencies have been generally observable—one, to increase the powers of the synods at the expense of the consistories (*see* 17.142), the other, to vest the spiritual oversight of the church in a single official, known as bishop, chief pastor, or some other equivalent title.

Two problems have presented especial difficulties. The one is the problem of aim and purpose. Is the Church to continue, under new forms of administration, to be the one recognised institution of religion for that state (*Volkskirche*), or is it to be an institution for the promulgation of a single doctrinal type of Christianty (*Bekenntniskirche*)? The second problem concerns the relation of the Church to the state schools. No fully satisfactory solution of either problem has been reached as yet, though the idea of the *Volkskirche* seems, for the present, to have the stronger following, and the general trend is toward a separation of the Church from the schools.

The acute economic depression of 1922–4 affected most disastrously those elements of the laity from which the greatest measure of church support was to be expected, and it subjected the clergy to severe privations. All the activities of the churches were impaired, and the great voluntary associations for Christian work—the societies for foreign and inner missions—were practically paralysed. Substantial financial support was furnished during this crisis by Lutherans of foreign countries, especially of America, and with the beginning of economic recovery the normal church activities were, by 1926, gradually being resumed.

Central European Countries.—The formation of the new national states of Poland, Latvia, Estonia, Czechoslovakia, Yugoslavia and Hungary has been followed by a new organisation of the Lutheran churches in those countries. The same tendencies that were operative in Germany have shown themselves in these lands. The churches have tended to organise with a large measure of self-support and self-government. Where entire independence of the state has not been feasible it has been apparent as the ultimate aim. An episcopal form of spiritual oversight has also been introduced into most of these churches. All of them have had to contend with economic difficulties similar to those in Germany.

Russia and Rumania.—In 1924 the Lutherans of Russia were permitted, for the first time in their history, to organise as a Russian Church with a synod and two bishops. In Rumania, on the other hand, the disestablishment of the Transylvanian Lutheran Church has caused severe, if temporary, hardships.

Organisation.—The membership statistics for the Lutheran churches of Europe are, as a rule, quite unreliable. This is especially true of those countries where the churches have been in organic connection with the state, and where all those who did not formally withdraw were counted as members of the state church.

On questions of doctrine the same divergences (*see* 17.142) continue to exist. The more conservative element has been organised since 1868 in the General Lutheran Conference (*Allgemeine evangelisch-lutherische Konferenz*), an international society for the maintenance of confessional Lutheran teaching. In 1922 the conference united with the American National Lutheran Council in the calling of the First Lutheran World Convention, held at Eisenach, Germany, in Aug. 1923. The members of the convention came from 20 different countries, including the United States and Canada, and effected a new international organisation, with an executive committee of six members, charged especially to secure co-operation among the Lutherans of the world in works of mercy, foreign missions and care for migratory Lutherans, and "in cases of emergency to speak for the whole Lutheran Church." The Lutheran Alliance is a society of ultra-conservative Lutherans, the members of which are drawn chiefly from the free churches of Germany.

II. IN THE NEW WORLD

United States and Canada.—In 1924 the Lutheran Church in the United States and Canada had 2,622,554 communicant members divided among 20 ecclesiastical bodies. The largest of these were the United Lutheran Church (856,180), the Missouri Synod (645,969), the Norwegian Lutheran Church (299,213), the Augustana Synod (217,616), the Iowa Synod (168,266), the Joint

nod of Ohio (161,021), the Joint Wisconsin Synod (139,226),
e Lutheran Free Church (30,320), the Danish Church in
nerica (20,045) and the Finnish National Church (20,000).
ie Synodical Conference, a consultative federation, comprising
e Missouri Synod, the Joint Wisconsin Synod and two smaller
dies, formed a single well-defined group with a membership of
ore than 800,000. The names of many of these bodies point
one of the reasons for their separate existence. At their
ganisation nearly all of them were expressions of the church
nsciousness of groups of immigrants from the Lutheran coun-
es of Europe, and they continue to perpetuate, to a greater
smaller degree, the religious tradition of the countries of their
gin. With the slackening of north European immigration
ward the end of the 19th century the nationalistic traits tended
become less marked, and the process of Americanisation was
eatly hastened by the World War. Since 1914 the foreign
iguages are rapidly being replaced in the services by English
d the separated bodies have been drawing closer together.

Organisation.—In 1918 the United Lutheran Church was
rmed by the union of the General Synod, the General Council
d the United Synod in the South. These three bodies repre-
ited a single line of American tradition reaching back to colo-
il days. Most of their synods owed their foundation, directly
indirectly, to the work of Henry Melchior Mühlenberg, the
eat colonial missionary (d. 1787). They had had doctrinal
ferences, but these were regarded as too small to keep them
iger apart. The Augustana Synod, a body of Lutherans of
edish origin, did not enter the union, though it had been a
rt of the General Council. In 1917 three bodies of Norwegian
therans united to form the Norwegian Lutheran Church in
ierica. Since 1921 discussions have been in progress looking
vards the union of other separated bodies. The National
theran Commission for Soldiers' and Sailors' Welfare was or-
iised in 1917 to minister to the spiritual welfare of the 400,000
theran men in the army and navy of the United States. Its
mbership included all the larger bodies except the Missouri
l Wisconsin Synods. It was dissolved in 1921. The National
theran Council was organised in 1918 by the same bodies that
l previously organised the commission. Its purpose was to
vide an agency for certain kinds of co-operative work. Its
st important task has been to extend aid to the Lutheran
irches of Europe during their period of reconstruction. Be-
een 1918 and 1925 it distributed among the Lutherans of 20
erent countries more than $6,500,000 in money and goods.

Doctrines.—Doctrinally, the Lutherans of America are pro-
inced conservatives. All of them subscribe to the Augsburg
nfession and the Small Catechism, and most of them accept
whole body of the 16th century Lutheran confessions. Their
ctrinal differences have been, at times, acute, but have usually
cerned the theological interpretation of the confessions. Their
m of government is theoretically congregational, but the
ole tendency in the larger bodies is towards a rather highly
tralised synodical administration. The most conservative
e of American Lutheranism is represented by the Synodical
nference. Its theological standards are those of 17th-century
hodoxy; it strongly opposes any recognition of or co-opera-
i with other churches, and it is vigorously hostile to the mem-
ship of its pastors and people in secret societies. The United
heran Church, though insistent upon the enforcement of
fessional standards, is less rigid both in theology and
ctice.

UTSK: *see* Luck.

LUTYENS, SIR EDWIN LANDSEER (1869–), British architect, was born in London March 29 1869. After a brief training in the South Kensington Schools and in architects' offices, he received his first commission at the age of 19. He afterwards designed a number of country houses, in which he gradually developed an individuality of design which was, however, tempered by a reticence which dissociated his work from any attempts at "originality." Much of his domestic work was done in connection with the restoration of old houses; the largest example of his powers in this direction is the treatment of Lindisfarne Castle, Holy Island (1903–12). He also executed much civic work, being responsible for the *Country Life* offices in London and for the British sections at the exhibitions in Paris (1900) and Rome (1911). The garden suburb at Hampstead, London, has many good examples of his treatment of small houses. It was as the architect of the New Delhi (*see* Delhi) that the culmination of his professional career was reached. He also designed the Cenotaph in Whitehall, London. Sir Edwin, who was knighted in 1918, became an associate of the Royal Academy in 1913 and was elected a full academician in 1920. The Royal Institute of British Architects awarded him its gold medal in 1921.

LUXEMBOURG (*see* 17.145), a neutral and independent Grand Duchy, in economic union with Belgium. Its area is 1,034 sq. m., and the population 267,447 (1922). Luxembourg was admitted to the League of Nations on Dec. 16 1920.

Invasion of 1914.—On Aug. 2 1914 the German armies invaded the Grand Duchy on the pretext that it was necessary to protect the German control and working of the Luxembourg railways against a French invasion. The main line of the railways of the Grand Duchy, which belongs to the railway company of *Guillaume-Luxembourg*, had been first worked by the French railway company of the East, but from 1872, by a condition of the Treaty of Frankfurt, by the German state railways. On Aug. 4 Herr von Bethmann Hollweg admitted to the Reichstag that the violation of Luxembourg neutrality was wrong, and promised reparation.

The invasion was a violation of the Treaty of London of May 11 1867, which had placed the neutrality of the Grand Duchy under the collective guarantee of Great Britain, Austria, France, Prussia and Russia. The Luxembourg Govt. and the sovereign protested against this violation, but the Grand Duchy remained in German occupation for the duration of the War. After the Armistice, the railways of Guillaume-Luxembourg were provisionally run by France.

After the evacuation of the country by the German troops, Luxembourg denounced its accession to the German Zollverein, to which it had belonged since 1842, and from Jan. 1 1919 it constituted an autonomous customs territory, while, by virtue of articles 41 and 268 of the Treaty of Versailles, it enjoyed the right of exporting to Germany for five years, duty free, goods equivalent in quantity to its average pre-War export to Germany.

The Dynasty.—Political complications decided the Grand Duchess, Marie-Adelaide, who had succeeded her father, Grand-Duke William, in 1912, to abdicate Jan. 10 1919, in order to save the independence of the Grand Duchy, and she was succeeded by her sister, Princess Charlotte, (b.1896). The latter married on Nov. 6 1919 Prince Felix of Bourbon-Parma, brother of the ex-empress Zita of Austria. Marie-Adelaide died Jan. 24 1924.

By the referendum of Sept. 28 1919 the Luxembourg people pronounced by 66,811 votes for the maintenance of the monarchy with the Grand Duchess Charlotte as sovereign, as against 16,885 votes for a republican régime, and by 60,133 votes for an economic union with France against 22,242 votes for an economic union with Belgium. Association with France would have helped the agrarian interest, while the vinegrowers stood to gain from association with Belgium.

Customs Union with Belgium.—After the occupation of Frankfurt, carried out jointly by French and Belgian troops (April 8 1920), the French Govt. made a declaration renouncing the negotiation of a customs union with Luxembourg in favour of Belgium. Relations with Belgium had been strained as a result of the plebiscite, but the new negotiations between

Belgium and Luxembourg culminated in a Convention (signed July 25 1921) establishing an economic union between the two countries which came into force May 1 1922, to last for 50 years. The chief stipulations of this treaty are as follows:—

1. The customs frontiers between Belgium and Luxembourg are abolished, commercial treaties in the name of the Union are to be drawn up by Belgium, Luxembourg adopts customs legislation and tariffs from Belgium, but preserves her own customs administration. The customs receipts of the two countries, as well as the yield of the taxes on beer, vinegar, sugar, tobacco, margarine, etc., with the exception of the tax on alcohol are pooled, and the total, after deducting a certain sum calculated according to the price of cereals, and devoted to the encouragement of the cultivation of cereals in the Grand Duchy, is divided between Belgium and Luxembourg in proportion to the population, approximately in the proportion of 28 to 1.
2. The paper currency in the Grand Duchy of State notes, resulting from the withdrawal of German notes after the Armistice, is reduced to 25,000,000 fr., and may only include notes not exceeding the value of 10 francs. The remainder of the note circulation of the Grand Duchy is made up of notes of the National Bank of Belgium, except a circulation of 6,250,000 fr. in notes of the International Bank of Luxembourg, which has the privilege of issue.
3. The Belgian State should share in working all the Luxembourg railways (standard normal gauge).[1]
4. Belgian consuls have charge of Luxembourg interests wherever there are no Luxembourg consuls. This provision leaves in force the agreement of Jan. 7 1880, between the Netherlands and Luxembourg, which placed Luxembourg political interests under the protection of Dutch diplomatic representatives, in all countries where Luxembourg has no diplomatic agents, except in Paris, Berlin and Brussels.

Constitution.—By a law of May 15 1919 the constitution of the Grand Duchy was revised in a more democratic direction. The powers of the sovereign were limited, universal suffrage, with proportional representation, was instituted, and the franchise was conferred on women. But the most interesting innovation was the creation of the law of April 4 1924, of five Chambers for traders, industrialists, agriculturists, artisans, private employees and workmen, election to the Chambers being by electors in these occupations above the age of 21, and maintenance by compulsory contributions by the electors. These Chambers have the power to create and maintain institutions, the right to propose bills which must be submitted to the Chamber of Deputies, and they have a right to be consulted before laws affecting their professional interests are passed by the Chamber of Deputies.

Population.—According to the census of 1922, the population of the Grand Duchy was 267,447, that is 101 persons per sq. km.; of these 33,436 were foreigners, chiefly Germans (15,500) and Italians (6,170), the latter being employed chiefly in the mining and metallurgical industries. According to the last census of occupations in 1907, 36·8 % of the population was occupied in agriculture and gardening, 41·7 % in industry and mines, 12·2 % in commerce and transport. Since then the proportion in industry and commerce has certainly grown at the expense of agriculture.

The chief towns of the Grand Duchy are, besides the capital, Luxembourg, with 46,709 inhabitants, the three centres of the iron industry: Esch-sur-Alzette, 22,100; Differdange, 13,728; and Dudelange, 10,400 inhabitants.

Production, Industry and Trade.—In 1925 Luxembourg produced 5,984,000 tons of iron ore against 7,333,372 in 1913. There were, in 1925, 47 blast furnaces, out of which only 37 were going, which produced 2,344,000 tons of pig-iron as compared with 2,547,861 tons in 1913. The seven steel foundries of the Grand Duchy produced in 1925 2,084,000 tons of steel compared with 1,182,227 in 1913. German capital, which before the War dominated the metal works of the Grand Duchy, has been replaced since by Luxembourg, Belgian and French capital. Besides the factories which they own in Luxembourg, the Luxembourg metal companies own or control mines, collieries, blast furnaces, steel works and factories for iron and steel manufacture principally in France, Belgium, Germany and in Brazil. Their branches are established in all quarters of the globe.

Besides the ancient industries of sole leather, slates, metal co structions, china, explosives, gloves, drapery, woven wear, brewi and tobacco, long established in Luxembourg, new industries ha grown up, and have made considerable way. These are the cement dustry, which produced 75,441 tons in 1924, the manufacture sparkling wines, fancy leather and brushes.

Finance.—In 1913 the public consolidated debt of the Gra Duchy was about 10,000,000 francs. In 1925 this debt had risen, consequence of the charges which the State had to assume duri the War to assure the feeding of the population and to meet t deficits in the budget caused by the upheavals during and after t War, to 196,000,000, plus a loan of 175,000,000 issued in Belgium 1922 and intended for the exchange of notes of the Luxembou State for notes of the National Bank of Belgium. Since 1924 t State budget has been balanced.

Railways.—On May 13 1924 a Convention between t Governments of Luxembourg and Belgium was signed at Bru sels. Under the terms of this Convention the entire railw system of Luxembourg will be administered by the Société d Chemins de Fer Prince Henri, under the control of the Gra Ducal Govt., conjointly in so far as questions of intere to Belgium are concerned, particularly as regards transit, wi the Belgian Government. This agreement was completed by final protocol signed at Brussels on Oct. 14 1924, which settl the economic and technical questions, relating to the Belgia Grand Ducal and French interests, raised by the separation of t Guillaume-Luxembourg railway system from that of Alsac Lorraine.

(A. C.)

LUXEMBURG, ROSA (1870–1919), German Socialist, w born at Zamość, Russian Poland, Dec. 25 1870. Having tak up socialist political activities in Poland, about 1895 she m grated to Germany, where she married a German workman order to acquire German nationality. In 1898 she edited t Saxon *Arbeiterzeitung*, but shortly afterwards joined the staff the *Leipziger Volkszeitung*. She took part in the Russian rev lution of 1905, and on her return to Germany founded with Ka Liebknecht the Spartacus League. In 1914 she was sentenc to a year's imprisonment for inciting to insubordination a throughout the World War remained in preventive custod After the revolution she edited, with Liebknecht, the Co munist paper, *Rote Fahne*. They were arrested on Jan. 15 19 on the charge of instigating the street fighting in Berlin whi had taken place a few days earlier. Whilst being conveyed to t Moabit prison they were brutally attacked by the mob. Lie knecht was shot dead and Rosa Luxemburg died a few hou later from injuries received.

BIBLIOGRAPHY.—Her works include *Die Krise der Sozialdemocra* *Briefe aus dem Gefängnis* and *Briefe an Karl und Luise Kautsk 1896–1918*. See also G. Zinoviev, *Karl Liebknecht et Rosa Luxembu* (1919); C. P. A. F. Liebknecht, *The Murder of Karl Liebkne and Rosa Luxemburg* (1924).

LVOV, PRINCE GEORGE EUGENIEVICH (1861–), Russi statesman, belonged to the old Russian nobility. He spent t greater part of his life in Zemstvo, that is, local governme work (*see* 23.876), being a member of the executive board of t Tula Zemstvo from 1888 and president from 1902–5. In 19 he was elected member of the first State Duma and joined t right wing of the Constitutional Democratic party. During t Russo-Japanese and World wars he took an active part in t organisation of Zemstvos for the relief of sick and wound soldiers and in the latter war was president of the All-Russi Union. On March 14 1917 Lvov was elected Prime Minist and Minister of the Interior of the first Russian Provisional Go ernment. Unfortunately his Government proved a comple failure. A new Coalition Cabinet was formed on May 16 a Lvov again accepted the leadership of the Cabinet and t portfolio of the Interior, but he had no real influence in politic life, and he resigned from both offices on July 7. (*See* RUSSIA After the Bolshevist revolution in November, Lvov was arrest and imprisoned in Ekaterinburg but he escaped to Siberia a eventually settled down in Paris.

---

[1] Long negotiations on the railways question ended in a convention, signed at Brussels on May 13 1924, under which the Luxembourg system is administered by a Luxembourg company, the Belgian Govt. acting conjointly with the Luxembourg authority where Belgian interests, particularly transit interests, were concerned. But this Convention was rejected by the Luxembourg Chamber of Deputies on Jan. 20 1925. Therefore the line is still under French control. The negotiations between Luxembourg, Belgium and France over the Luxembourg railway are still continuing.

YALL, SIR ALFRED COMYN (1835–1911), British writer
17.148), died in the Isle of Wight April 10 1911.

YAUTEY, LOUIS HUBERT GONZALVE (1854–   ), French
ier, was born at Nancy (Meurthe-et-Moselle) Nov. 17 1854.
ing passed through St. Cyr and the Staff College, he first
ed as a cavalry officer, and was then appointed in 1894 to the
of the troops in Indo-China, where he took part, under
eral Galliéni, in the operations against the pirates of Upper
gking. He accompanied General Galliéni to Madagascar,
re he distinguished himself by repressing an insurrection and
is able government of the southern part of the island. He
ied himself to working out and putting into practice new and
ently successful methods of colonial government. Having
rned to his regiment as its colonel, he was soon after ap-
ted to the command in the territory of Aïn Sefra, which was
g disturbed by incursions from Morocco. He was then
ed in command of the Oran division, and was entrusted with
carrying out of international agreements with regard to
occo. Having restored order on the Algerian-Moroccan
tier, as far as Moulouya and Guis, he took command of
X. Corps at Rennes.

April 1912, in view of the serious situation at Fez, the Gov-
nent decided to send him to Morocco as high commissioner
résident-général to quell disturbances and to consolidate the
ntly declared protectorate. Immediately on his arrival he
eeded in relieving Fez, and initiated the work of pacification
colonisation which was to result in a few years in the creation
well organised government on a solid basis. On the declara-
of the World War, although formally ordered by the Govern-
t to evacuate the interior of Morocco, so as to liberate the
ter part of his forces, he did not yield an inch of ground, and
ntained for four years a glorious struggle against all the efforts
enemy subsidised by Germany, while he actually increased
subjugated territory.

Dec. 1917 General Lyautey was appointed War Minister,
resigned after three months in order to return to Morocco.
n 1920 to 1924 he continued his work by conquering the At-
and by establishing a defensive barrier to the north of Ouer-
As a reward for these services he was made a marshal of
ce in Feb. 1921. In 1925 he organised a victorious resistance
e attacks of the Rifi under Abdel-Krim, and did not resign
ost of résident-général until order was completely restored.
work of Marshal Lyautey in Morocco was of considerable
rtance. Not only was the country pacified by the adoption
dicious methods of colonial government, but by construc-
work and fine organisation a province was built up with a
economic future (*see* MOROCCO). He was made a member
e French Academy in 1914, and wrote numerous articles on
ial administration. His letters from Tongking and Mada-
ar were published in 1920. (M. GU.)

NN, Mass., U.S.A. (*see* 17.172), increased in population
89,336 in 1910 to 99,148 in 1920, of whom 27,858 were for-
born, and 103,147 in 1925 (Massachusetts census). The
egate value of its manufactures rose from $71,503,000 in
to $160,906,000 in 1919, while the number of wage-earners
e factories remained unaltered. The effect of the post-War
ession and of the dispersion of the boot and shoe industry is
in the figures for 1923: value of products, $95,935,221;
ber of wage-earners, 22,506. From second place in 1905,
had fallen to sixth in 1923 in the manufacture of boots and
, ranking after New York, Brockton, St. Louis, Haverhill
Milwaukee. In 1917 a lock-out in the shoe factories (April
Sept. 20) affected 15,000 workers. The commission form
vernment, adopted in 1910, was abandoned in 1918 for a
ter providing for 11 councillors and for a mayor with large
rs.

ONS, SIR JOSEPH (1848–1917), British business man, was
in London Sept. 29 1848 and educated at a Jewish school.
arly life he studied painting and exhibited at the Royal
tute, but by 1886 he had turned to business enterprises,
njunction with the brothers Isidore (d. 1920) and Montague
kstein. This led to the foundation of the catering firm of J. Lyons and Co., Ltd., of which he became chairman. He began by catering at public exhibitions, and next opened tea-shops in London, the first in 1894. Twenty years later these numbered over 200 and provided cheap food for the large class of clerical workers and junior members of professions. Later he opened several restaurants of a more ambitious nature, as well as hotels on the no-tipping principle. He was knighted in 1911, and died in London June 22 1917. See Mrs. Stuart Menzies, *Modern Men of Mark* (1920).

LYONS, France (*see* 17.174), had a population of 561,592 in 1921. In 1922 about 140,000 persons were employed in the silk industry and several large factories were built in 1924. The manufacture of artificial silk is of growing importance. The international fair, first held in 1916, has shown a notable increase of business and aims at rivalling Leipzig. A permanent exhibition building on the banks of the Rhône was nearing completion in 1926, and space for exhibitors was also being reserved on both sides of the road on the left bank of the river and in the square near the main railway station. Poland and Soviet Russia were represented at the exhibition for the first time in 1923. The Wilson bridge over the Rhône was opened in 1918. From 1916, during the War, Lyons was a centre for the exchange of seriously wounded French and German prisoners. A syndicalist congress was held in the city in 1919.

LYS, BATTLE OF THE: *see* GERMAN OFFENSIVE.

LYTTELTON, ALFRED (1857–1913), British politician, was born Feb. 7 1857, the youngest child and eighth son of the 4th Lord Lyttelton. His mother, daughter of Sir Stephen Glynne and sister of Mrs. W. E. Gladstone, died six months after his birth. All the eight boys were brought up to be keen cricketers, the cricket ground at Hagley, Worcs., their home, being close to the house; all went to Eton, and six were in the Eton eleven. The eldest, VISCOUNT COBHAM (1842–1922), became a land commissioner and a railway commissioner; GEN. SIR NEVILLE LYTTELTON, G.C.B. (b. 1845), an experienced soldier, was governor of Chelsea Hospital; SPENCER LYTTELTON, C.B. (1847–1913), was three times private secretary to his uncle W. E. Gladstone when Prime Minister; the RIGHT REV. ARTHUR LYTTELTON, D.D. (1852–1903), was Bishop of Southampton; and the REV. EDWARD LYTTELTON, D.D. (b. 1854) was headmaster, first of Haileybury, and then of Eton.

Alfred was the most famous cricketer of them all. Indeed for nearly all ball games he had an extraordinary aptitude. He excelled in football of three kinds, and in fives, racquets and especially tennis—holding the amateur championship for tennis from 1882 to 1896. At cricket he was equally good as a bat and as a wicket keeper. He was four years, 1872–5, in the Eton eleven, and captain the last year; four years, 1876–9, in the Cambridge eleven, and captain the last year. Moreover, he played for England against Australia, and for the Gentlemen against the Players; and for some years was a notable member of the Middlesex eleven. The infectious joyousness of his nature, his sterling character, his solid, though not brilliant, intellect and his prowess at games gave him an undisputed lead among his contemporaries. He was king of the place before he left Eton; and when he went up to Trinity College, Cambridge, in 1875, he gained a similar ascendancy.

After taking his degree with a second class in history, he was called to the English bar in 1881. Here his reputation stood him in good stead; he soon obtained a considerable practice, and in due course became K. C. His thoughts turned early to politics. Though by family tradition and in idealistic outlook a Liberal, he found himself unable to support the Home Rule policy of his uncle, W. E. Gladstone, and so postponed any attempt to enter Parliament until after the latter's retirement. But in 1895 he became M.P. for Warwick and Leamington as a Liberal Unionist, retaining the seat till 1906, when he was defeated. After a few months' interval, he was returned for a London constituency, St. George's, Hanover Square.

He was appointed, in 1900, chairman of a commission to enquire into the various concessions which President Kruger and the Volksraad had granted to companies and private individuals in the Transvaal, and to report which should be maintained and which annulled. In pursuance of the investigation he spent the autumn of 1900 in South Africa; and he so impressed Lord Milner by his qualities that the high commissioner hoped to secure him as his successor. It was, however, as Colonial Secretary, in the Conservative Govt. of Mr. Balfour in 1903, that his South African experience was utilised. His tenure of office lasted two years and was marked by the drafting of a temporary constitution which should give representative institutions to the Transvaal until such time as it should be safe to concede responsible government. This constitution was never put in force, as Sir Henry Campbell-Bannerman's Ministry determined that they would risk the grant of responsible government at once. He incurred much odium by sanctioning the scheme for importing Chinese coolies into South Africa in order to remedy the shortage of native labour and to restart the mines and thereby the whole economic machinery of South Africa. When his party went into opposition he took an active sha resistance to the drastic Liberal policy, and especially to Welsh Disestablishment Bill, which was repugnant to him man of deep religious feeling and an earnest Churchman. also lent a helping hand to many social movements, and w decided supporter of woman suffrage.

His first wife, whom he married in 1885 and who died in was the brilliant Laura Tennant, sister of Lady Oxford an quith; his second wife, married in 1892, was Edith So daughter of Archibald Balfour. She, with a son, Captain O Lyttelton, and daughter, survived him. His death came unexpectedly, on July 5 1913, after an injury in a local cr match. Mr. Asquith, then Prime Minister, spoke of him i House of Commons as having come nearest, of all men o generation, to that ideal of manhood to which every En father would wish to see his son aspire. See Edith Lytte *Alfred Lyttelton*, 1917. (G. E.

McADOO, WILLIAM GIBBS (1863–), American lawyer and politician, was born near Marietta, Ga., Oct. 31 1863. He entered the University of Tennessee but did not finish his course. In 1882 he became clerk in U.S. circuit court of Chattanooga, read law and three years er was admitted to the bar. He began practice in Chatta-oga, but in 1892 removed to New York City. There he became erested in the problem of passenger transportation. In 1902 formed the New York and New Jersey Railroad Company, ich took over the abandoned Hudson river tunnel from Ho-ken to New York, and in March 1904 this tunnel was com-ted. In 1909 the tunnel under the Hudson river to down-vn New York was finished. In 1912 he was vice-chairman the Democratic National Committee. He was a strong sup-ter of Woodrow Wilson for president, and on the latter's ction he was appointed, in 1913, Secretary of the Treasury. this position he contributed largely to the working-out of the v Federal Reserve Banks system.

At the outbreak of the World War in Europe he favoured ict neutrality. After America's entrance into the War he was led upon to raise unprecedented sums of money. He was suc-sful in floating four Liberty Loans between May 1917 and t. 1918, amounting in all to more than $18,000,000,000. also secured the creation of a Bureau of War Risk Insurance shipping, later extended to include life insurance for soldiers d sailors in the World War. When the railways were taken er by the Federal Government in 1917 he was appointed ector-general. He favoured the League of Nations, woman frage and the prohibition amendment. He resigned the secre-yship of the Treasury in Dec. 1918, and the directorship of lways the following January. He then resumed the practice law in New York City. At the Democratic National Conven-n held at San Francisco, June 28 1920 and following days, Mr. Adoo was placed in nomination for the presidency, and on first ballot obtained the highest number of votes, 266; at the h ballot his vote ran to 399, but after that he lost ground, d J. M. Cox received the nomination on the 44th ballot. Mr. Adoo was again placed in nomination for the presidency at Democratic National Convention held at New York City June 1924. On the first ballot he obtained the highest number votes, 431½, on the 69th ballot he had 530, but after that his ength steadily declined, and on the 103rd ballot, when J. W. vis was nominated, he received only 12 votes. Mr. McAdoo rried, as his second wife, Eleanor Randolph, daughter of sident Wilson.

MACARTHUR, MARY REID (1880–1921), British politician, s born Aug. 31 1880 in Glasgow, where her father had a large pery establishment. Breaking with the Conservative tradi-ns of her family, in 1903 she came to London to be secretary the Women's Trade Union League, into whose work she athed new life. In 1906 she founded a new general trade un-for women—the National Federation of Women Workers. The ti-Sweating League, which she helped to found, and her evid-e before the Select Committee on Home Work did much to vince the public of the necessity of the Trade Boards Act, sed in 1909. It was mainly due to her efforts that boards were ablished in various sweated industries. In 1914 she became retary of the Central Committee for the Employment of men. Later she was instrumental in improving the condition he women War workers. In 1911 she married W. C. Anderson, was chairman of the Labour party in 1914 and M.P. for Atter-e (Sheffield) from 1915–8. In 1918 she unsuccessfully contested urbridge in the Labour interest. After her husband's death in 9, she lectured, mainly on peace, in the United States ch she again visited for the Labour Convention conference Washington. She died on Jan. 1 1921, leaving one child, a ghter, born in 1915.

ee M. A. Hamilton, *Mary Macarthur: a Biographical Sketch* (1925).

McBRIDE, SIR RICHARD (1870–1917), Canadian politician, was born at New Westminster Dec. 15 1870, and was educated first in that city and later at Dalhousie University, Halifax, Nova Scotia. He was called to the Canadian Bar in 1892, and entered the British Columbian parliament as member for Dewdney in 1898. In 1900 he became minister of mines and in 1902 leader of the Opposition. In June 1903 he became Prime Minister for the province and retained that position until 1915, when he became agent-general for British Columbia in London. He was made K.C.M.G. in 1912 and died in London Aug. 6 1917.

M'CARTHY, JUSTIN (1830–1912), Irish politician and writer (*see* 17.200), died at Folkestone, Kent, April 24 1912.

McCORMICK, ROBERT RUTHERFORD (1880–), American editor, was born in Chicago, Ill., July 30 1880. He graduated from Yale University in 1903, studied law at Northwestern University law school and was admitted to the Illinois Bar in 1908, commencing practice in Chicago. He was active in civic circles from 1904 to 1910. In 1910 he became associated with his cousin, Joseph Medill Patterson, as co-editor and publisher of *The Chicago Tribune*, being president of the Chicago Tribune Company. Under their direction the *Tribune* enormously increased both in circulation and the amount of advertising matter carried, becoming one of the most influential papers in the United States. In 1916–7 McCormick served as major in the 1st Illinois Cavalry on the Mexican frontier, and in 1917 was attached to Gen. Pershing's staff, A.E.F., in France. Later he was transferred to the 5th F.A. of the 1st Div., and promoted to the rank of colonel. In 1921 in conjunction with his cousin, he started in New York City a daily illustrated paper, followed in 1924 by *Liberty*, a weekly publication, both of which obtained immediate and large circulations. In 1912 they organised the Ontario Paper Co. to make paper for their newspapers, followed in 1924 by the Tonawanda Paper Co., to make magazine paper, the two producing in 1925 about 500 tons of paper a day.

MACCUNN, HAMISH (1868–1916), British composer (*see* 17.209), died in London Aug. 2 1916.

MACDONALD, JAMES RAMSAY (1866–), British politician, was born on Oct. 12 1866 at Lossiemouth, a little fishing village on the Moray Firth. His father was a labourer, his first home a "but and a ben." At Drainie Board School he received an elementary education and continued as a pupil teacher. Coming to London at 18, he worked at 12/6d. a week as a clerk. He continued his own education by evening classes, laboratory work and incessant reading. A breakdown in health ended his dream of a scientific career, and sent him to journalism.

MacDonald's experience and reading made him a convinced socialist. He joined, in 1894, the Independent Labour party, founded by Keir Hardie, and in 1895 stood, unsuccessfully, for Southampton. As a member of the London County Council he completed his training for public service, and, after his marriage, in 1896, with Margaret Ethel Gladstone, niece of Lord Kelvin, made frequent journeys abroad. In 1897 he paid his first visit to Canada and the United States; in 1902 he went to South Africa; in 1906, travelled through the Pacific to Australia and New Zealand; in 1910, visited India, whither he returned in 1913 and 1914 as a member of the Royal Commission on the Civil Service. At meetings of the Socialist International, he was the spokesman of British Labour on the Continent.

Stages of His Career.—Three main stages may be noted in his political career: the creation of the Labour Party, the War and the Labour Government. In the 'nineties, the great trade unions still stood aloof from politics, or were satisfied with a vague alliance with the Liberal party. The propaganda of the Independent Labour Party, with which he was prominently associated, was directed to convincing the Unions of the need of a political party for Labour; in 1899 the Trade Union Congress was induced to set up a committee to consider parliamentary action. Out of this came the Labour Representation Committee, of which Mr. MacDonald was secretary. Thanks to his energy, patience and tenacity, the hostility of some Unions and the apathy of others was broken down and a Labour party came into being in 1900. After the return of 29 M.Ps., run by the Labour Representation Committee in 1906, the battle was won; the party became an effective force. But it was in 1918 that Mr. MacDonald's ideas were fully realised. The party was reorganised and thrown open to all workers by hand or brain, and in 1925 had over 3,000,000 members.

Elected as M.P. for Leicester in 1906, by 1911 he was leader of the Labour party in the House of Commons. A constructive critic of Sir Edward Grey's foreign policy, he opposed, on Aug. 4 1914, the view that there was an "obligation of honour" to go to war. The speech was an agreed one, but the majority of the party broke away. He had already refused suggestions of office; he now resigned his leadership. He was denounced in public and private, and had to face the fact that his views were not accepted by the nation at war. In 1918 he lost his seat at Leicester, and in 1921 failed to get in for East Woolwich.

Although out of the House of Commons till late in 1922, his influence on opinion steadily grew. By 1922, the party took his view of the Peace Treaties, and resisted the tendencies that split nearly every Labour party abroad. In 1912, he had countered the demand for the substitution of industrial ("direct") for parliamentary action in *Syndicalism;* in 1919, when, under the stimulus of Russian events, this demand reappeared as the Communist doctrine of force, he wrote *Parliament and Revolution* and *Parliament and Democracy*, in which he gave a definite and logical lead against the tactics of violence and championed parliamentary democracy. The 1922 election registered his moral ascendancy. Labour, with 140 members, was the second party in the state, and he himself, returned for Aberavon, was chosen by his colleagues leader of the Opposition.

His leadership produced a marked change in public opinion, and focused general interest on himself and on Labour. He raised its claim to be fit to govern at the sudden election of 1923, and came back with 192 followers. The Conservatives had been defeated on the main item in their programme, and, at a great meeting in London, Mr. MacDonald declared that Labour would take office, if given the chance, in order to render national service. On Jan. 21 1924 he accordingly moved a vote of no confidence in the Unionists, which was carried with Liberal support. Next day the King called upon him to form a Government. The first Labour Cabinet was announced on Jan. 24, and on Feb. 12 the new Prime Minister set out its general programme in the House of Commons. In this, the first item was peace; with this supreme object in view, he took the post of Foreign Secretary in addition to that of First Lord of the Treasury.

The unsettled state of Europe, aggravated through the occupation of the Ruhr, was a primary cause of distress and unemployment in Britain. British prestige had fallen low: relations between Britain and France were bad, between France and Germany threatening. The Reparations question blocked the way. In letters to M. Poincaré, published on Feb. 4 and March 3, Mr. MacDonald, with firm friendliness, set out the British point of view, and had soon created a new atmosphere, one of confidence and hope. When, on April 13, the Experts Committee on Reparations issued a unanimous report, he at once accepted it on the part of Britain as a basis for settlement. In May, M. Poincaré was replaced by the Radical M. Herriot, who in June came over to London to discuss the European position with Mr. MacDonald. Friendship with Italy had already been established by the latter's action on Jubaland.

On July 16 1924 an Allied conference assembled in London, over which he presided, for the specific purpose of putting the Experts' Report into operation. Within a fortnight, agreement had been reached and the German delegates called in. On Aug. 16 the London Settlement, the first negotiated agreement since the War, was initialled. By mutual consent, the Experts' Plan was put in effect, and the Reparation problem thus lifted out of the political sphere. France, at the same time, agreed to evacuate the Ruhr within a year and certain towns at once. Negoti
tions for an Anglo-German Commercial Treaty, since signe
were initialled. In Sept. Mr. MacDonald and M. Herriot a
tended the Fifth Assembly of the League of Nations at Genev
and there submitted a plan, the Protocol, for the elimination
private war and the submission of all disputes to arbitratio
after general mutual disarmament.

In the House of Commons, meantime, the difficulties of t
Government's minority position were growing. Mr. Snowden
Budget met with general approval; a Housing Act was passe
and the machinery for the relief of unemployment improve
But when Mr. MacDonald sought to complete his peace work b
making treaties with Russia, whose *de jure* recognition had be
his first act as Foreign Secretary, the Liberals broke awa
In Oct. the Government was defeated on a motion, calli
for a select committee, on their dropping of the prosecuti
of a Communist named Campbell. In the general electio
then declared, the press was exceedingly hostile, and Labo
was identified with Bolshevism. The campaign culminated
the publication of a document purporting to emanate from
Zinoviev, president of the Moscow International, urging Briti
Communists to tamper with the army, and of a note from t
Foreign Office, issued without the signature or sanction of t
Secretary, animadverting on Russian propaganda. Polling to
place on Oct. 29; as a result the Conservatives came back wi
a great majority. The Labour vote went up by over a millio
but its representation was reduced to 150. On Nov. 4 Mr. Ma
Donald resigned, and resumed his leadership of the Oppositio
His party, in conference in 1925, confirmed his leadership wi
striking enthusiasm, and expressed its pride in the achieveme
of its first Government. In 1924, while Prime Minister, he w
given an LL.D. by Glasgow University, and made a freeman
Glasgow, and of Dundee. In 1925 Edinburgh made him a fre
man, and the university conferred an LL.D.

An Estimate.—The permanent significance in British politi
history of a man who had created a new political party and e
abled it to conduct a Government, is obvious. But Mr. MacDo
ald's contribution cannot be measured by this unless it is al
noted that he made the party the vehicle of a new political phil
ophy, which serves to give precision and content to the idea
democracy. His socialism, derived from wide study of men a
institutions, of science and history, has been expressed throu
writings and speeches which have modified opinion over a wid
range than that of professed adherents. In it, two main strea
may be detached—the scientific and the moral. Accepting t
design suggested by evolution, he postulates, instead of a ha
hazard and unwilling adaptation, or the resistance to chan
that provokes revolution, a conscious acceptance of its princi
through a planned social organisation based on commu
need and service—such an "organisation of things as invi
the co-operation of minds." Mind, in his view, is the instrume
consent the method, of social advance. Consistently rejecti
violence, he opposes war and revolution alike. A steadying
well as a constructive force in the British Labour movement,
realised that ideas are the moulding force in human developme
the moral element colouring his thought and action, gave to
appeal to the masses the accents of a gospel.

MacDonald's views on socialism can best be studied in his boo

IACDONELL, SIR JOHN (1846–1921), British jurist, was
n at Brechin, Forfarshire, Aug. 11 1846, and was educated
he universities of Aberdeen and Edinburgh. He was called
he bar by the Middle Temple in 1873 and for some years
counsel to the Board of Trade and the London Chamber of
nmerce. In 1889 he was made a master of the supreme court
in 1912 was appointed king's remembrancer. In 1901 he
made Quain professor of comparative law in the University
ondon and he was president of the society of public teachers
law (1912–3), a member of several royal commissions, and
ior, for many years, of *The Journal of Comparative Legislation*
International Law. In 1913 he was elected a fellow of the
tish Academy and in 1914 was created K.C.B. Besides
ting the *State Trials* (1887), the *Civil Judicial Statistics*
om 1894) and the *Criminal Judicial Statistics* (from 1900), he
blished works on the subjects of capture at sea and the law of
ster and servant, and was the author of many papers on
ernational law. He was also for 40 years a leader writer on
Times, London. He died in London March 17 1921.

IACEDONIA (*see* 17.216), a territory embracing the former
rkish vilayets of Monastir and Salonika, and part of the
ayet of Kosovo, now divided between Greece and Serbia.

ll statistics of Macedonian nationalities must be received
h the greatest caution and have a very relative value. The
eace Handbook for Macedonia" states with considerable
idence that "before 1912 there were approximately 1,150,000
vs, 400,000 Turks, 120,000 Albanians, 300,000 Greeks,
,000 Vlachs, 100,000 Jews and 10,000 Gipsies." M. Palles
imates the population of Greek Macedonia as 43% Greek
ore the immigration of the Greek refugees and as 90%
eek in 1925. There is a movement among the Greeks of Greek
cedonia for local government; this is quite distinct from the
lgarian propaganda in favour of an "autonomous" Mace-
ia, which, like "autonomous" Eastern Roumelia in 1885,
ld be ultimately annexed to Bulgaria.

olitical History.—Since 1911 Macedonia has thrice become a
tlefield. When the first Balkan War of 1912 broke out, while
Bulgarians directed their principal efforts against the
rkish armies in Thrace, their Serbian and Greek allies ad-
nced into Macedonia. The great Serbian victory at Kuma-
vo left Skoplje, the capital of Dushan's medieval Empire, open
the victors, and the Greek successes at Sarantaporos and
nije-Vardar led to the occupation of Salonika. In 1913 the
arrel which arose out of the division of the Macedonian spoils
ween Bulgaria and her allies provoked the second Balkan
r, of which Macedonia was again the theatre. The Greeks
eated the Bulgarians at Kilkis and the Serbians routed them
Ovčepolje. But the retreating Bulgarians laid Seres, a flour-
ing town, in ashes, and the writer, visiting it a year later, saw
empty petroleum tin in every Greek house. Violence was
practised at Nigrita, Doxaton and Drama.

he third Treaty of Bucharest, signed Aug. 10 1913, divided
cedonia between Greece and Serbia; the Greek frontier
etched from the Mesta, thus including the rich tobacco
ntations of Kavalla, to Kenali near Monastir, which became
bian. Bulgaria was excluded from what had been to her
tionalists her "promised land," and King Constantine was
led at Athens as a second "Bulgar-slayer," the successor of
sil II. For the first time for five centuries Macedonia was
verned by Christian nations. As inevitably happens when-
r Turkish rule ceases there was everything to create. The
tors of the wars of 1912–3 took over a land neglected com-
tely by its Turkish governors; its marshes were undrained,
rivers unembanked, its ports undredged, its cultivable lands
th the exception of the tobacco fields) either uncultivated or
cultivated by the most primitive methods. Serbians and
eeks set to work upon this colossal task to the best of their
perience and limited means, but they had had no time to
ieve much when in 1914 the World War broke out, and in
5 Macedonia for the third time in three years became the
ne of Balkan conflicts and was soon converted into one of the
ropean cockpits.

The entry of Bulgaria into war against Serbia, on Oct. 14 1915, was speedily followed by the capture of Shtip, Radovište, Veles and Skoplje and the evacuation of Monastir, although the Serbians held the Babuna pass between Skoplje and Prilep for more than a week. Meanwhile, the Allied troops had landed at Salonika (*q.v.*) on Oct. 5, which thenceforth became the base of their operations in Macedonia. But they had to retreat from Doiran and Krivolak to the Vardar and thence to Salonika in Dec., while in May 1916 the strategic position of Fort Rupel, commanding the Struma valley, was, with the acquiescence of the Greek Govt., betrayed to the Bulgarians, who occupied Kavalla and all eastern Macedonia. At last, after the appointment of Gen. Sarrail as commander-in-chief, the Allied offensive began. The British advanced on Doiran and along the Struma; the French and the reconstituted Serbian Army retook Monastir, while Italian troops landed at Salonika and the Provisional Govt. of M. Veniselos, now established there, on Nov. 23 declared war on Bulgaria and Germany. When the spring campaign of 1917 began, fighting was resumed near Monastir and Doiran, and the French and Russians extended their front towards the lake of Okhrida, while the Greeks at the battle of Srka in 1918 contributed to the Allied victory. The Franco-Serbian offensive on the Vardar in Sept. of that year, combined with the Anglo-Greek attack near Doiran, where a monument now commemorates the British fallen, led to a complete rout of the Bulgarians, who on the 25th asked for an armistice, signed on the 29th, on the day when the French entered Skoplje. Next day Bulgaria surrendered unconditionally; Macedonia had contributed her share to the defeat and at last had rest.

The peace settlement of 1919 divided Macedonia between Greece and Yugoslavia, while Bulgaria was excluded alike from Macedonia and the Aegean. But that she will permanently acquiesce in that settlement may be doubted from a study of her past claims. Bulgarian *komitadjis* still threaten from time to time the danger zone where the three frontiers converge. Incidents such as that between Greeks and Bulgarians near Petritch in Oct. 1925, referred by both parties to, and settled by, the League of Nations, remind western Europe that Macedonia is still volcanic soil.

Greek Settlement in Macedonia.—The emigration of the Greek refugees from Asia Minor and Turkish Thrace after the Greek disaster in the Asia Minor campaign of 1922 has, however, completely changed the ethnographical situation, and has solved the racial question in Greek Macedonia, whose population, formerly only 43%, is now 90% Greek. Economically the change is equally striking. Thanks to the work of the Refugees' Settlement Commission, created by the League of Nations in 1923, and to the Refugee Loan of £10,000,000, issued under the auspices of the League, villages have arisen throughout parts of Greek Macedonia where there was not a house before. Competent judges believe that the refugees from Asia Minor will in time do for Macedonia what the expelled French Huguenots did for England, for they have brought new industries with them. It is calculated that when the Anglo-American concession for draining the Vardar marshes has accomplished its work, not only will malaria, the curse of Macedonia, be diminished, but also that country will supply the rest of Greece with cereals, now imported, and will thus improve the rate of exchange.

Railway Communications.—Since the opening of the last section of the Greek railway between Thessaly and the Macedonian system in 1916—a connection long refused by the Turks—Macedonia is traversed by the Simplon-Orient and Prague expresses to Athens, and an improvement of the permanent way will further shorten the journey. Difficulties between Greece and Yugoslavia have, however, arisen with respect to the portion of the railway between Salonika and the Yugoslav frontier station, Gjevgjelija, which belonged to a French company, now bought out by the Greeks. The Yugoslavs have obtained a "Serbian zone" in the port of Salonika, but, despite the fact that since Aug. 1925 Serbia has for the first time had direct railway communication with the Adriatic at Spalato, Serbian nationalism tends to regard Salonika—towards which the Croats and Slovenes are indifferent—as the natural outlet of Serbian Macedonia. The signature of the Bulgarian Minorities' Protocol by the Greek representative at Geneva was the occasion of the denunciation by the Yugoslavs of their alliance with Greece, and the subsequent negotiations for its renewal had (up to April 1926) failed, although the Greek Assembly refused to ratify the Minorities' Protocol. Meanwhile, considerable improvements have been made, notably in the railway stations of Serbian Macedonia, and the frontier question of the Monastery of St. Naum has been settled with Albania.

Production and Industrial Development.—But it would be impossible for Macedonia, after five centuries of Turkish neglect, to achieve a high grade of civilisation in 13 years. Nevertheless, Macedonia has already shown signs of an industrial future. Cotton is grown near Seres, woollen goods are produced and 17,000 tons of tobacco were grown in 1924, and 26,000 in 1923 in Macedonia and Thrace. The refugees have replaced the Turkish tobacco planters in Macedonia, and in 1924 they were cultivating 2,250 acres more than before. In 1923 the value of the tobacco exported from Kavalla reached three milliards of *drachmai*, and an American tobacco company is established there. The usual corollary of industrialism has made its appearance at Kavalla in the form of the labour disputes of 1924. Macedonia is, indeed, the only part of Greece where there are any signs of Bolshevism, a phenomenon to the growth of which the individualism of the Greek character is very unfavourable. The Greek peasant is naturally conservative, and it is only among the new elements of the Macedonian population, Greeks who in some cases speak only Turkish and have little to lose, that Bolshevik propaganda can find disciples.

Jewish Element.—Macedonia is the only Greek territory which furnishes a large Jewish element to the population. The Salonika Jews, settled there for centuries, probably preferred Turkish to Christian rule; but they have accepted Greek citizenship and formed a special electoral college for the elections to the new Greek Senate (still in abeyance). Their traditional business qualities contribute to the economic development of the province, now placed under a governor-general. *See* also Bulgaria.

Bibliography.—N. B. Many books on this subject have racial bias and are propaganda. See however: Peace Handbooks, vol. 4, No. 21, *Macedonia* (1920); Gen. M. P. E. Sarrail, *Mon Commandement en Orient, 1916–8* (Paris, 1920); William Miller, *The Ottoman Empire and its Successors, 1801–1922*, ed. 2 (Cambridge, 1923); R. F. H. Duke, *Report on the Industrial and Economic Situation in Greece for the Years 1923 and 1924* (London, 1925). (W. Mi.)

McGILL UNIVERSITY (*see* 27.775).—The position of McGill as providing exceptionally ample facilities for instruction and research in applied science has been maintained and strengthened since 1910 in many respects. A new wing giving additional space to the work in electrical engineering has been erected. A university clinic has been established under direction of the professor of medicine who is also chief medical officer of the Royal Victoria Hospital. In 1910 the Carnegie Corporation of New York gave $1,000,000 in recognition of McGill's science and sacrifice in the World War. In 1920 the Rockefeller Foundation gave $1,000,000 for the faculty of medicine, $1,000,000 was given by the Provincial Govt. for general purposes and $4,400,000 was raised from the graduates and citizens of Montreal as a general endowment. The income from investments is about $1,000,000. In 1923–4 the Rockefeller Foundation gave $500,000 for medical research, Lady Strathcona gave $120,000 to endow a chair of zoology, and other substantial gifts and bequests have been made to the university since 1910. After the World War Sir Arthur Currie, G.C.M.G., K.C.B., was chosen principal of the university.

MACH, ERNST (1838–1916), Austrian physicist and psychologist (*see* 17.232), died near Munich Feb. 19 1916.

MACHAR, JAN SVATOPLUK (1864–), Czech poet, was born at Kolin Feb. 29 1864. His early works, such as *Confiteor* consist of sentimental verses written under the influence of Lermontov, Heine and De Musset. He afterwards turned his attention to social and political satire, exemplified in such volumes as *Magdalena* (1894), and *Warriors of God* (1895–6). The most important phase of his poetical activity began, however, with the publication of *Golgotha* (1901), the first of a series of volumes in which the destinies of mankind are surveyed through sceptical and anti-clerical eyes. *In the Glow of the Hellenic Sun* (1906) and *The Poison from Judaea* are titles which sufficiently indicate the point of view from which Machar wrote his historical impressions. He traced, in the form of monologues, portraits and short dramatic scenes, the chief personalities in history, from the earliest times to the Napoleonic era and beyond. As a prose writer, Machar exhibits the same incisive qualities which distinguish his poetry. He attracted much attention by his book, *Rome* (1907) in which personal bias is fully expressed and by *The Jail* (1917–8), a graphic descript of his imprisonment by the Austrian authorities during World War.

MACHINE GUNS (*see* 17.237).—The machine gun is an au matic small-arm weapon, usually provided with a fixed mount and capable of sustained accurate fire. A heavy machine does not differ materially from an ordinary machine gun design, but as its calibre may be from 0·5 to 0·9 in. it is ne sarily of a heavier and stronger make. The weight of a mach gun, however, is limited by the consideration that by whate means it may be transported, it must in the last resort "man-handled" into position often over considerable tances and under difficult conditions. On the other hand lig ness and portability are desirable only in so far as they consistent with strength, for to a large extent it is on the streng and therefore, weight, of the mechanism that the ability o gun to sustain fire depends.

Ammunition.—Rifle ammunition can be projected by machine gun with incapacitating effect at ranges at which fire of the rifleman would be inaccurate and wasteful owing the big variation caused by the personal error. Theoretically might be desirable to have special machine gun ammuniti such as the long-ranging (6,000 yd.) streamline bullet us by the United States and Swiss armies; but in view of the en mous quantities of ammunition required for the small arms modern armies, it seems probable that any advantage wou be more than counterbalanced by the difficulties of supp organisation, etc., that would be involved in having differe types of ammunition for rifles and machine guns.

Mounting.—The fixed mounting with which the machine g is provided increases the accuracy of all ordinary shooting, a thus enables the gun to be used either for indirect fire, or fire over the heads of friendly troops, when supporting attack or covering a retirement. To support rigidly a machi gun weighing from 40 to 50 lb., the mounting must be strong a fairly heavy, otherwise the combination will be top heavy a unsteady, and the shooting in consequence will be inaccura The mounting must permit of the gun being traversed throu as wide an arc as possible, and also permit alterations in elev tion to be made. The tripod mounting of the American Browning machine gun has elevating and traversing dia graduated in degrees, etc., to facilitate "fire direction."

Fire Capabilities.—Machine guns for ground use normally ha a rate of fire of about 450–500 rounds per minute, but, owi to the necessary replenishment of empty belts or magazines, et the number of rounds actually fired per minute is much les In aircraft a higher rate of fire is desirable, and is usually o tained. By reason of its capacity for sustained fire the machin gun can provide prolonged supporting fire on the battlefie besides being useful for barrage work. The ability to fire sing shots is an advantage, because such shots do not disclose t identity of the machine gun and are useful for observation range, for testing the working and for keeping water-cool guns from freezing up in cold weather. There are also certa tactical advantages, especially in the case of detached units cavalry, whose ammunition is on pack transport and is ther fore limited.

Cooling Systems.—For sustained fire an efficient cooling syste for the barrel is essential. The higher the temperature of t barrel, the less its resistance to wear. There are three systems use, namely, radiation in air, a combination of radiation a draught of air and water-cooling. In the case of aircra machine guns no special provision for cooling is necessary as t barrel is exposed to the rush of cold air. Heavy barrels wi radiating rings are sometimes employed for ground use (*e.g.*, t French Hotchkiss). Such barrels are comparatively safe fro damage by ordinary usage or by small-arm bullets, but th suffer from the disadvantage that when they get hot, the heate air rising from them, known as "mirage," causes the target t appear to be in movement, and thus interferes with the aimin of the gun by eye. The radiation and the draught system employed in Lewis guns (*see* Rifles and Light Machine Guns 'he water-cooling system is the most common. The barrel, nearly the whole of its length, is surrounded by water con- ied in a casing which, in the case of recoiling barrels, is fitted n glands to prevent leakage. Inasmuch as prolonged rapid causes the water to boil, a steam escape is necessary. In l countries the renewal of the water given off as steam is n a serious difficulty, and in any case there is always the : of the escaping steam disclosing the position of the gun. ordingly a flexible tube is usually attached to the steam es- e whereby the steam is led into a portable condensing mber, and converted back into water for use again in the gun. cold weather guns having recoiling barrels may be put out action, except for single shots, by the water freezing, but no ance is known of a water-cooled gun being out of action by son of heat, provided the water-casing has been kept well plied. The water increases the weight of the gun by about b., and for this reason light machine guns rely on radiation their cooling.

lechanical Safety.—All automatic weapons are required to be echanically safe," that is, the design must be such that the cannot be fired unless the action is fully closed and the tridge properly supported. Even then, it should only be e to fire by means of the trigger mechanism, which itself must proof against heavy jarring. Safety catch (" applied safety ") ices are usually operated by a single, simple movement. be perfectly efficient, they should operate directly on the ng pin or striker, and should preclude the possibility of its r being able to reach the cartridge by accident.

Typical Patterns.—A few details of typical different patterns machine guns are given in the table at the bottom of the page. lgaria used a ·315 Maxim (tripod mounting and pack trans- t) and Switzerland a ·295 Maxim (tripod and reff carriage, k and man's back). In other details both guns follow the rman pattern. The Belgian Hotchkiss differs from the French calibre (·301), mounting (carriage with removable tripod) l mode of transport (limber). The Czechoslovak Schwarzlose dentical with the Austrian weapon.

For the automatic operation of machine guns power may be obtained in three distinct ways, viz.: from the gases generated by the explosion of the charge, from the recoil of the barrel and from the backward thrust of the cartridge on explosion. In some types of gun two of these principles of operation are combined.

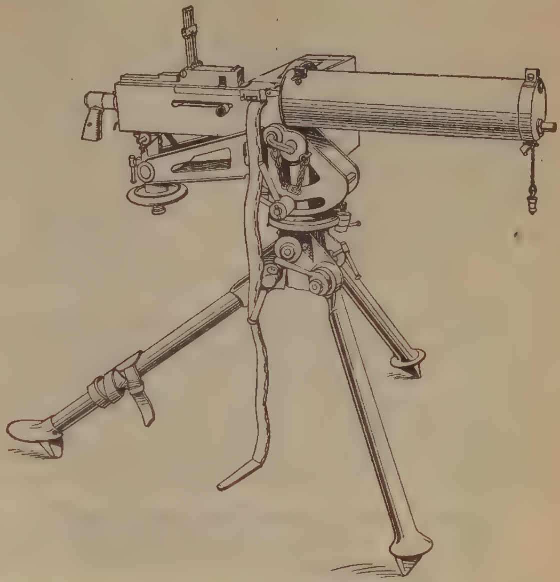

FIG. 1.—Browning water-cooled machine gun (U.S.).

Gas-Operated Guns.—Most light machine guns and the Hotchkiss, which is the primary machine gun of the French Army, are typical of the first method. The gas is diverted through a hole in the barrel near the muzzle to operate a piston or lever. In the Colt machine gun the gas issuing from a hole near the muzzle impinges

[1] Rearward thrust of cartridge projects breech block to rear.

[2] During the World War the Erfurt gun was made. It was very similar to the 1908 gun, but weighed less—empty 31 lb., full 37 lb. Tripod ½ pounds.

[3] Mark II. gun is for aircraft. It is air-cooled and uses a metal disintegrating link belt (any length).

[4] Belts for aircraft are of metal disintegrating links.

on the front end of a lever hinged at its rear. The front of the lever, being blown down by the gases, revolves backward round its hinge and in so doing extends springs which operate the mechanism. This gun is now practically obsolete.

Barrel Recoil Only.—The U.S. Browning water-cooled gun (see fig. 1) operates by barrel recoil alone. On the explosion of the cartridge the barrel, barrel extension and breech block move backwards locked together for $\frac{5}{8}$ inch. The locking block for the breech block is then forced downwards, and, the action being unlocked, the breech block travels to the rear, compressing the return spring. An extractor pivoted to the breech block then withdraws a live round from the belt in the feed block. At the end of its rearward travel, it is forced down, so placing the new round in grooves on the face of the breech block and in line with the chamber. The empty cartridge case is knocked off the face of the breech block through the ejection opening underneath the gun. The return spring then pushes the breech block forward to close and load the gun. The cartridge belt is led into the feed block by the action of a slide carrying a pawl, which, engaging behind the leading round, forces it into position for the extractor to grip. In this way the belt is led through the gun. A pawl on the floor of the feed block prevents the belt from slipping backwards. The slide is worked to left and right by a lever operated by a stud working on a cam-shaped slot in the top of the breech block.

The firing pin, housed within the breech block, is cocked by the action of a pivoting lever during the backward travel of the breech block. The other end of this lever, engaging with ramps on the top of the gun, is caused to rotate round its pivot. When the breech block goes forward it is pivoted into position for the next cocking action. To release the firing pin to fire the gun, a trigger, when the breech block is fully forward and locked, engages with a sear which holds back the firing pin against its spring. In this way, the "mechanical safety" of the gun is secured. When the trigger is pulled, the sear disengages from the firing pin, which then flies forward to fire the round. So long as the trigger is pressed the gun fires automatically. A springed component called the accelerator is also embodied. Its function is to assist the recovery of the barrel and, cocked by the barrel extension moving backwards and released by the breech block going forward, regulates the timing of the locking of the latter.

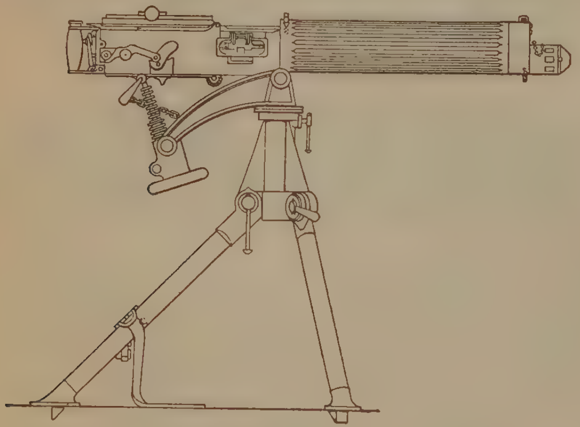

FIG. 2.—Vickers machine gun (Great Britain).

Recoil and Gas.—In the Vickers gun (see fig. 2) recoil of the barrel is assisted by the backward thrust of the gases partially trapped at the muzzle. The barrel projects through the front of the water casing, and on it is carried a muzzle cup. Surrounding this is a muzzle attachment, screwed to the water casing and having a small hole in it, through which the bullet passes. The gases following the bullet strike the front end of this attachment and rebound on to the muzzle cup on the barrel, so increasing the recoil energy of the latter. The barrel, with side-plates attached, recoils about one inch. The left side-plate operates a lever, which, with another, works a slide on the feed block, to the right on recoil and to the left on recovery. This feed block is above the breech. The slide has two pawls, which, when it is to the right, engage behind the new round in the cartridge belt and push it to the left into position, where it is withdrawn from the belt by the moving extractor on the lock.

On recoil the lock, locked to the barrel, moves with it. In the rear of the lock is the crank to which the lock is connected by the head of the side levers and connecting rod, in which the former engages. Bearings in the rear of the right and left side-plates carry the crank, the left one being detachable. On the right, outside the casing, is a crank handle. This handle has a curved rearward extension called the tail. Just clear of this tail on the side of the gun is a roller. On recoil, the curved part of the tail hits this roller and is caused to rotate. Being attached to the crank, the latter is rotated, thereby causing the lock to be unlocked and withdrawn from the breec during which movement the lock is cocked. There is, farther fo ward on the crank handle, a hump, which, when meeting the roll causes the crank and side-plates to move forward, so returning t barrel to its forward position. In the left axis of the crank is a reces into which a feathered lever called the fuzee engages. This, means of links, engages with the fuzee spring, which is secured to t left of the casing. When the crank rotates, the fuzee rotates, and th spring is extended. When the rearward rotation of the crank finished, the spring, working through the fuzee, rotates the crank the opposite direction, so causing the lock to go fully forward into t locked position against the breech, with its firing pin cocked. Th extractor is operated vertically on the lock face by side and extract levers. It has two flanges in which the cartridge rims ride and are held to it.

When the lock is fully forward, the extractor is at its highe point, and if a round be in the feed block, it is gripped by the extra tor. When the lock goes back, this round is withdrawn from th belt, and, after about $3\frac{1}{2}$ in. of travel, the extractor falls and plac the round in line with the chamber. When the lock goes forward th round is pushed into the chamber, and the extractor, rising agai grips another round in the feed block, there being then two round on the extractor, one in the feed block, the other in the chamber. Through the extractor is a hole, through which the firing pin protrudes to fire the round in the chamber when the extractor is in its highest position. On the recoil of firing, the flanges, still gripping the case in the chamber, withdraw it, and when the extractor drops again, this empty case drops through the bottom of the casing.

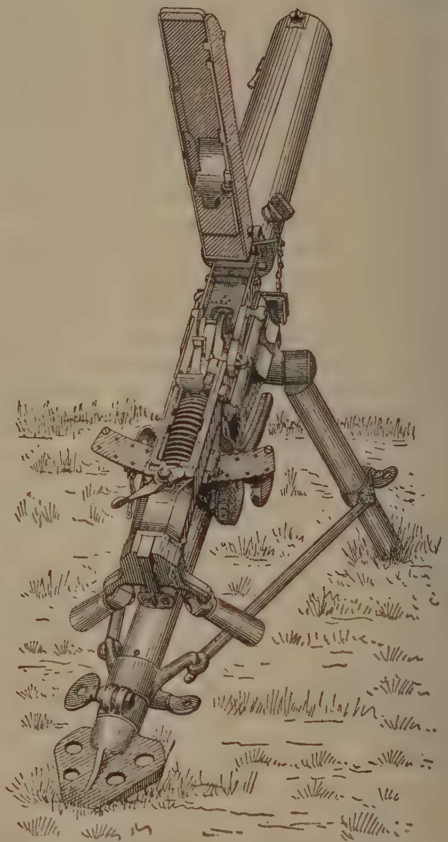

FIG. 3.—Schwarzlose machine gun (Austria).

Projecting from the top of the lock is the tail of the trigger. Along the cover of the gun is situated a spring-operated sliding trigger bar. The rear of this is connected by the trigger bar lever to the firing lever with thumb piece, which is carried on the rear crosspiece. When the thumb piece is pressed forward the trigger bar is drawn rearwards and pulls or trips the tail of the trigger projecting from the lock, thus releasing the firing pin and firing the gun. A spring-operated safety catch on the rear crosspiece prevents the operation of the thumb piece until disengaged by the fingers of the firer.

Cartridge Projection.—The Austrian Schwarzlose (see fig. 3) is operated on a principle known as "cartridge projection," *i. e.*, by the backward thrust of the cartridge driving the action to the rear. The barrel is fixed, and the moving parts are operated by the thrust of the cartridge head on the breech block. To ensure that the care does not grip the chamber after the explosion, and so retard its vard thrust, provision is made to oil each round entering the nber. On firing, the breech block is driven to the rear against a g spring, extracting the fired round from the chamber, and ing the crank and handle.

rear of and underneath the breech is the feed wheel, round which tuds. Underneath the bolt is a cam-shaped slot, in which each of studs ride in turn, thus causing a rotating movement of the feed el. At the front of the fore part are two sets of teeth. The belt is nto the gun between these teeth, which then engage the rounds ach end and lift them into position for withdrawal from the belt neans of a claw on the underside of the breech block. The round us drawn to the rear into a channel in the feed wheel. During withdrawal, the channel is rotated slightly to the left, so bring- he round into position in front of the breech block, which is now s rearmost position. The main spring then drives the breech k forward and the round enters the chamber, rotation of the feed el being also effected, and the next round being prepared for a lar operation.

jection is effected by a plunger on the right of the breech block A heavy firing pin protrudes through the breech block, and at ear is a solid arm that curves forward. This portion engages a suitably shaped similar arm in the crank, when the latter is ted during the backward travel of the breech block, thus with- ving the firing pin. When withdrawn, the bent of the firing pin ges with the sear on the breech block, and it is cocked. On the side of the solid arm of the firing pin is a pivoted arm, the trigger, ecting forward and downward. The front end of the trigger bar, ch is ramp shaped, is in front of this arm when the firing pin is ed. Its rear end is engaged with a trigger bar lever, operated by firing lever thumb piece, mounted on the rear cross piece. On humb piece is the safety catch. To fire the gun, the safety catch is sed towards the right and the thumb piece forward. This with- vs the trigger-bar, and the ramp at its forward end raises the ted arm, or trigger, until disengaging its bent from the sear on breech block, when the firing pin is free to fly forward to fire.

echanical safety is provided by (*a*) the cap of the cartridge not g in line with the firing pin hole till the breech block is fully ard, and (*b*) by the main spring bearing against the solid metal e rear of the firing pin, thus driving the breech block forward, so it is impossible for the firing pin to strike the cartridge cap if the ch block be not fully forward.

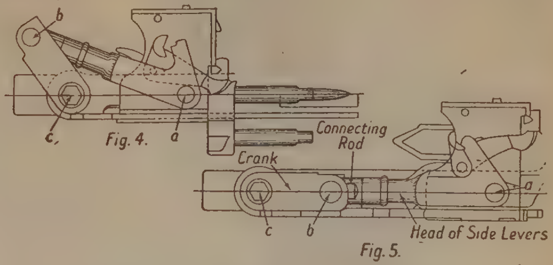
ecoil and Cartridge Projection.—The Italian Revelli uses a com- tion of barrel recoil and cartridge projection. At the rear of the el a sleeve is attached by means of ribs. Inside this sleeve is the ch block. When the gun is fired all three move together to the for a distance of 4 mm., after which the breech block goes on for about 6 in., compressing the recovery spring within it. This ng also operates the firing pin within the breech block. The bent he firing pin protrudes down through the breech block, and, when goes forward under the influence of the recovery spring, the bent ges with the right hand, or primary, of two sears projecting up- ds through the body casing. This sear is released by a spring nger connected to a thumb piece in the rear crosspiece, and is ngaged from the bent on the firing pin to fire the gun. By setting nall lever on the rear crosspiece, the spring plunger can be lated to give continuous or single shots. The secondary or left- d sear is to ensure "mechanical safety." If the sleeve and breech k are not fully forward, this sear continues to protrude and ges with the bent on the firing pin. It is operated by an arm truding from a rotary wedge underneath the sleeve. This wedge, spring, is rotated fully forward when the sleeve and breech block in their forward positions. Its arm then rises, and pressing up- ds the front end of the secondary sear, clears the rear end of this from the path of the bent of the firing pin.

he cartridges are contained in a magazine holding 50 rounds, e being 10 compartments, each with a platform and spring. As compartment is emptied, the magazine is moved to the right and next compartment is employed. The breech block, on going vard, takes the top round from the compartment and inserts it in chamber. The moving across of the magazine as the compart- ts are emptied is effected by a lever protruding from inside the y casing, and engaging in spaces in the magazine. This lever is t out of action by a spring plunger engaging with it, but, when the partment platform rises on being emptied, it disengages the ng plunger, so permitting the lever to function. The lever is on a ot, to one end of which is attached a strong spring. The other end his spring is connected to a system of levers working in short oves in the sleeve, every backward movement of which causes spring to extend and endeavour to produce the requisite motion he magazine lever.

echanical safety is further effected by means of a little rocking er on the left front edge of the breech block, into which one end jects. In the body casing is a recess for the other end of this er. The firing pin on going forward encounters the inner end and es the other end outward. Unless the breech block be fully for- d, the outer end is not in position to enter this recess in the body ing, and the firing pin is intercepted by the inner end of the lever, so preventing from protruding to fire the round. Ejection with gun is vertically upwards.

LOCKING ACTIONS

As the locking action is perhaps the most important part of the mechanism of any automatic weapon, a short description is given of the well-known method employed in the Vickers gun and also the unusual methods employed in the Schwarzlose and Revelli guns.



FIGS. 4 and 5.—Locking action of the Vickers machine gun.

The Vickers (see figs. 4 and 5).—The lock is connected to the crank by (1) the side lever head, whose axis is a, and (2) the connecting rod, whose axis is b. The axis of the crank is c. Fig. 4 shows the unlocked position with the lock back. Fig. 5 shows the locked position. In the locked position, axis b is slightly below axis a and c, and the crank, under b, bears hard on the crank stops. The rearward thrust of the cartridge on explosion thus passes through a, b and c. As b is lower than a and c, it cannot under pressure rise above the line ac and so unlock the action. It must tend downwards. However, the crank is already bearing on the crank stops under b, hence no movement here is possible and so the locking action is effected.

Except that the crank revolves downwards instead of upwards, the system of locking in the Maxim gun is practically identical with that employed in the Vickers.

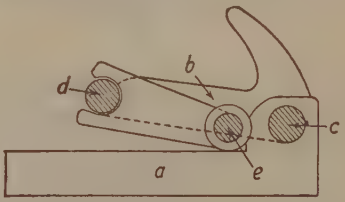


FIG. 6.—Inertia sealing of the breech in the Schwarzlose machine gun.

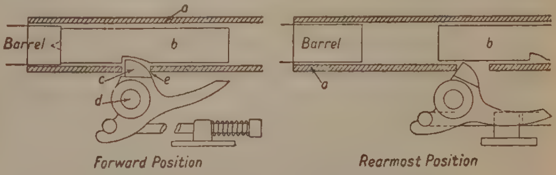
Inertia Sealing of the Breech in the Schwarzlose.—There is no positive locking in the gun, reliance being placed in heavy moving parts and a strong spring, to induce sufficient inertia to seal the breech. With a view to ensuring the exit of the bullet from the barrel before the inertia is overcome, the barrel is abnormally short.

The mechanism includes a massive, heavy breech block a (see fig. 6), connected by the crank link b (which is attached to it at axis c) to the upper axis of the crank, d. The lower axis of the crank e works in bearings in the body-casing of the gun and has no backward or forward movement. In rear is a strong spring pushing the bolt forward. The thrust on the face of the breech block pulls the crank link to the rear. It, in turn, pulls the crank to the rear.



Forward Position

Rearmost Position

FIG. 7.—Locking action of the Revelli machine gun.

However, owing to the set of the crank with reference to its non-recoiling axis e, considerable resistance to the rearward motion of the breech block is set up. Thus it is that, coupled with the heavy resistance offered by the strong antagonistic spring and the weight of the moving parts, sufficient inertia is created to prevent the breech from opening prematurely.

The Revelli.—On explosion, the barrel with sleeve a (see fig. 7) recoils, and the gases, acting through the cartridge head, impart a rearward movement to the breech block b. At this stage, the breech block and sleeve are locked together by a claw c, on a rotating wedge with axis d. The rearward movement of the breech block causes the wedge to rotate to the rear. In so doing, the claw, which passes through a slot in the sleeve, bears against the latter at the shoulder e, and helps to force the sleeve and barrel rearward. After a and b have moved about 4 mm., the claw is entirely disengaged from the breech block, which continues to the rear under its own momentum. The wedge in rotating compresses a strong spring, so the tip of the claw bears against the under side of the breech block, and is prevented from regaining its forward position. Hence the sleeve cannot do so until the recess in the breech block returns to within 4 mm. of its forward position.

The long arm of the wedge is that which engages with the secondary sear introduced for " mechanical safety " and referred to in the description of the gun. (H. R. A.)

MACHINERY: *see* AUTOMATIC MACHINERY; TEXTILE MACHINERY.

MACHINE TOOLS (*see* 27.21).—The sixteen years between 1910 and 1926 changed the character of machine tool equipment in many respects. For while the outward appearance may have retained the same general outline, there have been many developments in details that greatly affect productive capacity. Among these details are the use of heat treated alloy steels in spindles and gears, anti-friction bearings in many places, including the main spindle in a few instances, and the placing of the driving motor in the base of the machine itself. Add to these the growing use of individual motor drives, the speeding up of the machines and the tendency toward automatic or semi-automatic feeds, and the changes are very noticeable.

Mass production has been aided by the increasing use of more accurate gauges and better inspection methods. The new visual or projection methods of inspecting screw threads and other contours has enabled interchangeable work to be secured more rapidly. The use of optical methods has also made it much easier to obtain extreme accuracy whenever necessary.

Lathes.—There have been few changes in cutting tools since the advent of the tools suggested by the late Frederick W. Taylor although there is a tendency to use tools with greater top rake. Both A. L. De Leeuw and Dr. Hans Klopstock have advocated changes in tools shapes that, as shown by experiments, make a much higher cutting speed possible. The machines themselves have undergone distinct changes largely by the use of alloy steel shafts and gears, more and more ball or roller bearings and the introduction of automatic stops that put the lathe into the semi-automatic class. The use of multiple tools had also increased to a large extent.

The hand turret or capstan lathe has received much attention, both in making it more convenient to operate and in the methods of tooling. The tools have been simplified so as to enable a comparatively few standard tools to be utilised for a large variety of work, thus making the capstan lathe a more universal machine and materially reducing the cost of tools required for average work. Self-closing chucks, operated both by air and electric motor, are growing in favor where the work warrants. More attention is being paid to the proper lubrication of lathes as well as of other machines. Geared heads are run in oil and in some cases an oil pump forces oil to the main bearings, or to reservoirs, from which it is led to different bearings by suitable pipes. Convenience of operation has also been studied and much lost time eliminated in that way.

Boring and turning machines of the vertical type have advanced in design and in productive capacity. Continuous operation machines are more in evidence so as to avoid idle time while the work is being put in position. This is secured in the station type machine where the work indexes under the cutting tools, one station being left blank for loading the work. In other machines the work table continues feeding but there is sufficient time for the operator to remove the finished piece and replace it with a piece to be machined, before the tools feed into the work; or the feed can be tripped and again thrown in when the operator is ready. One of these, by the same maker as the Mult-au-matic, is called the Continu-matic. This is shown on the plate. There are now several machines built along these general lines.

Drilling and boring machines have been developed to a considerable extent by the demands of the automobile industry. These developments include the special multi-way, multi-spindle machines that drill a large number of holes in from three to five sides of a cylinder block, at one feeding of the drills. The number of holes drilled at once is limited only by the ability to get the spindles close enough together and by the power of the machine. Drilling machines are also made in the station type and many are semi-automatic in their action. In other cases a number of spindles are mounted in a row and work is passed from one to the other. The drills themselves have been improved to such an extent that higher speeds and more powerful motors are now necessary to secure maximum production.

Milling Machines.—While there have been but one or two really new types of milling machines put on the market, the changes in design and capacity have been very marked. Machines are being built heavier and more rigid and the controls are being centralised for the convenience of the operator. Rapid power traverse is universal to save the time and labour of moving the tables or knees by hand. Anti-friction bearings have been largely used in the gear boxes and for thrusts, and now roller bearings are being applied to the main spindle in a few cases. Automatic feeds and stops are being largely used to increase the production and every endeavour is being made to make the cutting action continuous wherever possible. A development along this line is to hold the work on a revolving table that carries it past the milling cutters and allows a new piece to be put in place while the machine is running. These revolving tables are made both vertical and horizontal. With the table in a vertical position and horizontal milling spindles each side of the table, both ends of the piece can be milled at the same time. In one machine of this type the work is held firmly in place by a chain so arranged that the work runs under it before the milling cutters begin working and releases it after the work has passed the cutters. This is a very simple device but one which saves much time and greatly reduces the cost of clamping the work to the table.

The planer type of milling machine is being used more and more in railway shop work on connecting rods and in similar work. We are also learning that a milling machine is only as good as its cutter, and that the designing and making of an efficient milling cutter is an engineering problem. The effect of this cutter development has been to double the feed per minute in many cases and to remove an unbelievable weight of metal per minute. For small pieces the tendency is to use the continuous milling machine rather than the planer type on account of the time lost in loading. On long work however it is still holding its own and the milling machine along the lines of the openside planer is being considered for a variety of large work, too large to go between the housings. Continuous lubrication and the use of motors in the base are also now a part of the development of the modern milling machine. Machines of the knee type are being adapted to special manufacturing by the addition of one or more spindles in a special head, the extra spindles being driven from the main spindle. This head and the use of special fixtures turns a standard milling machine into a single purpose machine that can be used on other work by the substitution of another spindle head.

Automatic profiling machines as shown have also been greatly developed by the addition of an electric contact device for the follower that makes it possible to use a master of wood or plaster or common building cement. This electric contact device controls the action of the profiling cutter, and though the touch of the follower is very light and delicate, the profiling cutter can take as heavy a cut as the machine or the work will stand. This type of machine not only secures extreme accuracy in the reproduction of any desired pattern but also effects a remarkable economy over the usual methods of making dies or profiling work of any kind.

Grinding Machines.—Grinding machines have probably been more startlingly developed than any other class of machine. Beginning with being practically a polishing machine that removed very small amounts of metal, we now have grinding machines that are driving the grinding wheel with a 75 H.P. motor, and removing metal at a rate that compares favourably with machines and cutting tools of other types. One type of grinding now finding favour is the in-feeding or " plunge-cut " type where a wheel is used that is wider than the length of the work and fed straight against the work instead of being traversed along its

gth. The present limit seems to be a wheel 10 in. wide. The treless grinding machine has also made great strides both as the quantity of work produced and the accuracy obtainable. such work as automobile piston pins which are fed through machine in a continuous string, the diameter can be well hin a half-thousandth, and with a high production. These s are also remarkably round. It is also possible to grind ulder work on the centreless but in that case the work cannot fed through the machine but must be ground by revolving it front of the wheel in a fixed position. Centreless grinding chines are being used on work up to eight or 10 in. in diameter.

Another development is in the application of automatic sizing chanisms to cylindrical grinding, both internal and external, stly the latter. These machines rough grind the holes at a id rate, then automatically reduce the feed as the hole ap- aches the finished size, and finally finish the hole with a ht feed and stop when the hole is of the correct size. Here the accuracy is well within a half-thousandth of an inch on nmercial work.

Grinding machines are being used to remove metal to a greater tent than ever before not only on large and heavy surfacing rk but in such work as the grinding of the threads in taps. stead of merely finishing the thread of a taps that has been eviously chased and hardened, some are now grinding the com- ete thread from the solid metal, and at a remarkably rapid rate. ydraulic feed has been gaining in favour on several types of achines but has been applied to grinding machines to a greater tent than to any other. Some broaching machines are now draulically driven and the same type of feed has been used on ring and other machines. The idea has been lying dormant for number of years but recent developments seem to have made very successful in some of its applications.

Honing or lapping has gained in favour during the past few ars to a remarkable extent. Honing as applied in automobile linder work, is in reality a method of grinding instead of what e formerly knew as lapping or honing. The hones have several rips or blocks of abrasive materials, turned on the outside to it the bore of the cylinder. These are moved through the linder from end to end and revolved at the same time, so that is really a grinding process with motion different from that of e grinding wheel. Some revolve the hones rapidly and trav- se them slowly through the cylinder. Others reverse this, while me make both movements at about the same speed. In most ses the hones are used directly after a finish reaming operation d so eliminate the grinding operation. On a few of the higher iced cars however the honing is an additional operation that irtually polishes the surface and removes the "fuzz" left by the inding wheel.

The use of magnetic chucks is being extended into new lines of ork, but is confined largely to the grinding machine field. These re now made in many styles and shapes to suit individual con- itions and are a great aid to production by reducing the time re- uired for chucking any magnetic metal that can be held in this ay, to a minimum.

Planing Machines.—Planing machines include shapers and lotters, which also embrace the special types built for gear utting. All of these with the possible exception of slotters have een much improved, and the slotter has been developed as a tool oom machine. The driving mechanism of planers has been vastly mproved, which means better bearings, better gearing and im- roved lubrication of the whole machine. More convenient con- rols, rapid power traverse on all movements and more rigidity in he machine have added much to its cutting capacity and to he smoothness of the cuts that can be taken. This also applies to hapers, both for regular work and of the gear cutting type. Higher speeds are now possible than ever before and the work s also of better quality.

Broaching and Swaging Machines.—Both broaching and swag- ng machines continue to find new fields of usefulness. Where rregular surfaces are to be machined, or with internal surfaces that are hard to get at in any other way, the broach is found of great value, in many lines of industry. Broaches are in reality a series of cutting teeth, each cutting a very small amount as the broach is pushed or pulled through the work. The push broach seems to be growing in favour in some classes of work, presumably because of the lower first cost of the broaches and the corresponding lower loss when they break in service. Swaging machines have changed very little except to increase in size and in some cases to be used more on hot work than formerly. The accuracy of the work depends largely on the machine in which it is done and the way in which the machine is cared for and adjusted. Sewing machine needles, spinning frame spindles and much other work, including steel balls, hollow balls used in electrical pull chains and in jewelry, and many other parts, are manufactured by swaging.

The rapid development of machine tools during the last decade has made many first class machines of ten years ago entirely obsolete where low cost production is essential. In some cases machines of this highly productive nature become obsolete in two years, sometimes less. (F. H. C.)

MACKAY, CLARENCE HUNGERFORD (1874–), American capitalist, was born at San Francisco April 17 1874, being a son of John William Mackay (*see* 17.250). He received his education in Europe and at the age of 20 entered his father's office in New York. After his father's death in 1902 he succeeded to his large interests. He was elected president of the Mackay companies, organised in 1903, and owning all the capital stock of the Commercial Cable Co. and a majority of the stock of various cable, telegraph and telephone companies in the United States, Canada and Europe, including the Postal Telegraph Cable Company. In 1921 the Mackay companies operated some 350,000 m. of wires and 29,000 m. of cables, connecting with all parts of the civilised world. Acting under authority of a joint resolution of Congress of July 16 1918, President Wilson took over the wires as from Aug. 1 1918 and placed them under the control of Postmaster-General Burleson. Mr. Mackay opposed many of the Postmaster-General's policies on the ground that he was using War-time control to bring about government ownership of the wires. In Dec. Mackay was removed from control of the Commercial Cable Company. In March 1919 he was also removed from the presidency of the Postal Telegraph Cable Co., but was reinstated after the return of the wires to their private owners in 1919.

MacKAYE, PERCY (1875–), American poet and dramatist, son of Steele MacKaye, actor-dramatist, was born at New York City March 16 1875. He has lived chiefly in rural New England and in New York City. After graduating from Harvard in 1897, he travelled and studied abroad (1898–1900). By his varied imaginative works, he created new forms in native drama and literature and instigated national movements for community theatres, folk-plays and poetry. His outdoor choral masques, performed in stadium-theatres by thousands of actor-citizens, have drawn large audiences.

His many works include—in poetry: *Poems* (collected, 1916); *Dogtown Common* (1921)—plays: *The Canterbury Pilgrims* (1903); *Jeanne d'Arc* (1906); *Sappho and Phaon* (1907); *The Scarecrow* (1908); *Yankee Fantasies* (1901–12); *Washington* (1918); *This Fine-Pretty World* (1923)—operas: *The Immigrants* (1915)—masques: *Saint Louis* (10,000 citizen-actors, 1914); *Caliban* (Harvard Stadium, 1917)—essays: *The Civic Theatre* (1912)—folk-stories: *Tall Tales of the Kentucky Mountains* (1925)—biography: *Steele MacKaye, Genius of the Theatre* (1926).

MACKE, AUGUST (1887–1914), German painter, was born on Jan. 3 1887 at Meschede, Westphalia. His youth was spent in Cologne and Bonn, and he received his artistic training, from 1904, at the Düsseldorf Academy and later in Berlin with Louis Korinth. He was influenced particularly in his earlier work by the older Impressionists: Cezanne, Matisse, Renoir, Picasso; and the Cubists. During his student days he went to Paris, Holland and Italy for the purpose of study. The period of his independent creation embraces the years 1909–14. With Kandinski, Jawlenski and Marc, he was one of the most important representatives of the "Blauen Reiter," the group of painters from which Expressionism in Germany originated. His art combines the cherished tradition of French painting, its sense of the grace of movement and atmosphere in landscape painting, with the cosmic sentiment of German art, without losing itself in the subtle and problematical. A journey to Tunis which he undertook in the spring of 1914 inspired some of his most beautiful pictures. He was killed in the World War at Perthes-les-Hurlus, Champagne, in Sept. 1914. See Walter Cohen, *August Macke* (Leipzig, 1922).

McKENNA, REGINALD (1863–), British politician and financier, was born in London July 6 1863, and educated at King's College. He went up to Trinity Hall, Cambridge, as a scholar and graduated as senior optime in 1885. He also gained distinction as an oarsman, rowing in the university boat race in 1887. He was called to the bar in that year, and in 1895 was elected Liberal member for North Monmouthshire. When his party returned to power in Dec. 1905, he became Financial Secretary to the Treasury. In 1907 he was promoted to the presidency of the Board of Education, but was no better able than his predecessor, Mr. Birrell, to draft a bill which would satisfy the Nonconformists and yet pass the House of Lords. His tenure of the office was brief, as, on Mr. Asquith's succeeding to the Premiership in the spring of 1908, he was transferred to the Admiralty.

He entered on his new duties at a time when the country was profoundly stirred by the rapid increase of the German fleet, and was in doubt whether the preparations of the Admiralty were on a sufficiently extensive scale. At the same time a large number of Liberals were disposed to belittle the danger and to call a halt to building schemes in the interest of peace and economy. Mr. McKenna, relying upon the advice of his First Sea Lord, Lord Fisher, resisted the section of the Cabinet represented by Mr. Lloyd George and Mr. Churchill, who took this last view; and, supported by the Prime Minister and Sir E. Grey, he persuaded his colleagues to begin the building of four battleships of the dreadnought type in 1909, and to ask for power, if necessary, to prepare for the construction of four more a year later. This programme disgusted the Radical economists, but did not altogether satisfy public opinion. The Conservatives and other friends of a big navy carried on an agitation to the slogan, "We want eight, and we won't wait"; and eventually in July Mr. McKenna announced that the second four dreadnoughts would definitely be ordered. The estimates of 1909 had shown an increase of nearly £3,000,000; those of 1910 showed a further increase of £5,500,000, mainly due to new construction. A still further increase of £3,750,000 in 1911 made it clear that Mr. McKenna and the Admiralty were in earnest in their determination to maintain "a fleet sufficient to hold the seas against any reasonably probable combination."

Work at the Exchequer.—From the Admiralty he went in the autumn of 1911 to the Home Office, and, as Home Secretary, had charge of the Welsh Disestablishment Bill. On the outbreak of the War, it was his duty—a duty on the whole satisfactorily accomplished—to safeguard the country against the machinations of spies. In the first Coalition Ministry in 1915 he was made Chancellor of the Exchequer, and a still more difficult task was imposed on him—to find the money to carry on the War. By a 4½% War Loan a subscription of nearly £600,000,000 was obtained. In the autumn he introduced a supplementary war budget, providing for over £100,000,000 by new taxation. Income tax was raised 40%, and the abatement and exemption limits lowered; the rates of supertax were seriously heightened; all the old duties on sugar, tea, tobacco, cocoa, coffee, motor spirit and patent medicines were almost doubled; the import of luxuries such as motor cars, cinema films, clocks and musical instruments was restrained by an *ad valorem* duty of 33⅓%; and an excess profits tax of 50% was imposed. Other methods of financing the War which he adopted were War Savings Certificates, which realised over £40,000,000 in their first year; 5% Exchequer bonds, replaced after a year for a short time by 6% Exchequer bonds: but for current expenses he relied mainly on the sale of Treasury bills. In his 1916 budget he raised taxation still further. Income tax was increased to 5s. in the £ and excess profits tax to 60%; there were further increases on sugar, cocoa and coffee; higher duties were imposed on motor vehicles; there were new taxes on amusements, railway tickets, matches and mineral waters.

Mr. McKenna went out of office with Mr. Asquith in Dec. 1916, and, along with other Liberal leaders who had refused to serve under Mr. Lloyd George, lost his seat at the general election of Dec. 1918. A year later he accepted the chairmanship of the London City and Midland (now the Midland) Bank and speedily gained a position of authority in the city of London. At the same time he showed increasing detachment from party feeling, and was ready, as an anti-Socialist, to accept the Chancellorship of the Exchequer in Mr. Baldwin's first Ministry, had it been found possible to provide him a seat without a party contest. He married in 1908 Pamela, daughter of Sir Herbert Jekyll, and had two sons. (G. E. B.)

MACKENSEN, AUGUST VON (1849–), German soldier, was born in Hausleipnitz, Saxony, Dec. 6 1849. Educated at Torgau and the University of Halle, he was commissioned to the army in 1869. By 1903 he was commander of an infantry division; and in 1908 he was given command of the XVII. Army Corps. At the outbreak of the World War he was placed in charge of the IX. Army on the Eastern Front, where he conducted successful operations against the Russians at Kutno, Łódź and Łowicz. In April 1915 he became leader of the German forces in western Galicia and was largely responsible for the German break-through at Gorlice. On June 20 1915 he was made a field-marshal and in Aug. and Sept. of that year had further successes at Brest-Litovsk and Pinsk. In Oct. and Nov. 1916, as commander of the army sent against Serbia, he practically overran that country; and in 1916, with the composite army which invaded Rumania, he subjugated the Dobruja and by the middle of Jan. 1917 had to all intents and purposes occupied the country. He remained in Rumania till the Armistice; and on his retiring into Hungary he was interned by the French at Neusatz, where he was detained till the beginning of Dec. 1919.

MACKENZIE, EDWARD MONTAGUE COMPTON (1883–), British novelist, son of Edward Compton, was born at West Hartlepool Jan. 17 1883, and educated at St. Paul's School, London, and Magdalen College, Oxford. He saw a good deal of stage life before embarking on his literary career which began with *Poems* (1907) and a picturesque "costume" novel, *The Passionate Elopement* (1911). *Kensington Rhymes* and the novel *Carnival* followed in 1912, the long novel *Sinister Street*, characteristic of the quasi-autobiographical novels of childhood and youth which were then attracting some of the younger novelists. Mackenzie served with the Royal Naval Division at the Dardanelles, and held a staff appointment at Athens in 1916. After the War he lived on the Channel Island of Jethou. His work is characterised by a coloured and mellifluous style, picaresque action and humorous character study and, in some of his best work, a sympathetic portrayal of religious sensibility. This last, for instance, is to be seen in the trilogy *The Altar Steps* (1922), *The Parson's Progress* (1923) and *The Heavenly Ladder* (1924). *Guy and Pauline* (1915), *Sylvia Scarlett* (1918) and *Coral* (1925) were successful developments of the *Carnival* and *Sinister Street* milieu.

MACLEAN, SIR DONALD (1864–), British politician, the eldest son of John Maclean of Kilmoluag, Tireé, Scotland, was admitted a solicitor in 1887. After three unsuccessful contests, he entered the House of Commons in 1906 as Liberal member for Bath. He failed to hold his seat at the general election of Jan. 1910, but in Dec. of that year he was elected for Peebles and Selkirk, which he represented until 1918. He was member for Peebles and South Midlothian from 1918 to 192, when he lost his seat. In the absence of Mr. Asquith, later Earl of Oxford and Asquith, from the House of Commons, he became chairman of the Parliamentary Liberal party, 1919–22, and after Mr Asquith was returned as member for Paisley in 1920, he continued to take an active part in debate. He unsuccessfully contested Kilmarnock in 1923 and East Cardiff in 1924. He was deputy chairman of committee, House of Commons, 1911–8, and chairman of the London Appeal Tribunal, 1916–8.

ring the War he was chairman of the Enemy Debt Treasury mmission and of the House of Commons military appeal bunal. He was sworn of the privy council in 1916, and ated K.B.E. in 1917.

IACLEOD, JOHN JAMES RICKARD (1876–), British ysiologist, was born on Sept. 6 1876, near Dunkeld, Scotland, l was educated at Aberdeen Grammar School, Marischal llege, Aberdeen, and Leipzig University. From 1899 to 1902 was demonstrator in physiology and then lecturer in biomistry at the London Hospital, holding also from 1901–3 Mackinnon Research Scholarship of the Royal Society; and m 1903 to 1918 he was professor of physiology at the Western serve University, Cleveland, Ohio, subsequently becoming fessor of physiology and director of the physiological labora- in the University of Toronto in Canada. His most important rk was on the nature of the control of the metabolism of carbodrates in the animal body, and, together with Dr. Banting, h whom he shared the Nobel Prize for medicine in 1923, he ieved fame as one of the discoverers of insulin (*q.v.*) and of its ue in the investigation and treatment of diabetes (*q.v.*), and also connection with other problems of metabolism. He was elected R.S. in 1923, and received the Cameron Prize of Edinburgh iversity in the same year. He has become a member of many entific societies and was president of the Royal Canadian stitute in 1925. (*See* PHYSIOLOGY.)

His publications include *Practical Physiology* (1903); *Recent Adces in Physiology*, edited by Leonard Hill (1905); *Diabetes, its ysiological Pathology* (1913); *Fundamentals of Physiology* (1916); *ysiology and Biochemistry in Modern Medicine*, 4th ed. (1922); l numerous papers on insulin, etc., published in *The Journal of ysiology* and *The American Journal of Physiology*.

M'NEILL, RONALD JOHN (1861–), British politician, was rn April 3 1861, the son of an Ulster landowner, Edmund 'Neill, and was educated at Harrow and Christ Church, ford. He became a barrister, but found a career in journalism d from 1901 to 1904 was editor of *The St. James's Gazette*, erwards assisting Mr. Hugh Chisholm in the preparation of 11th edition of *The Encyclopædia Britannica*. Having made eral unsuccessful attempts to enter Parliament, he was, in 11, returned as Conservative M.P. for a division of Kent. As olitician he was for some years associated with Sir Edward rson and the more strenuous opponents of Home Rule. When r. Baldwin formed his first ministry in 1922, Mr. M'Neill was pointed Under-secretary for Foreign Affairs; he held that office til early in 1924 and returned to it in Nov. of the same year ain under Mr. Baldwin. In 1925 he was made financial secre- y to the Treasury.

MacVEAGH, WAYNE (1833–1917), American lawyer and lomatist (*see* 17.269), died in Washington, D.C., Jan 11 1917.

MADAGASCAR (*see* 17.270) has an area of about 228,000 m., and a population (1911) of 3,153,511; (1921) of 3,272,301. 1921 Europeans—nine-tenths French—numbered 19,359, iatics 8,135. Tananarivo (Antananarivo), the capital, had 459 inhabitants. The Comoro Islands (*see* 6.794) were nexed to Madagascar in 1914. They had (1921) 109,860 habitants.

History.—French policy in Madagascar since the appointnt of M. Picquié as governor-general in 1910 has been rected not only to material development and to attracting ench settlers to the island but also to the training of the tives to ways and outlook essentially French. The former minant race, the Hova, who had adopted Protestant forms of ristianity and had the largest number of educated persons, s deprived of all trace of political ascendancy, and special atntion was paid to the Sakavala, the Betsimasakara and other ibes. Nowhere, however, was a purely native rule under ibal chieftains allowed. At the same time, large numbers of tives were employed in the French administration and the few alagasy who became thoroughly assimilated were given French izenship (there were about 150 native French citizens in 1924). Notwithstanding these measures, the growth of a sense of alagasy nationality could be discerned. Among the educated natives dislike of French rule continued strong for many years after the conquest of the island in 1896. Their discontent culminated during the World War in the formation of an anti-French secret society, whose members included a large proportion of the native officials. The existence of the society which, it was alleged, plotted the simultaneous "removal" of the Europeans by means of poison was discovered early in 1916. The society was rigorously suppressed and hundreds of Malagasy were condemned to hard labour in the Comoro Islands. The death of Ranavalona III., the last Queen of Madagascar, in exile in 1917, was a blow to Hova aspirations. Gradually, conditions in the island improved. Gradually, too, a better class of European official was sent out. The number of French functionaries was, however, large and was a drain on the scanty colonial revenue.

Malagasy troops were employed in considerable numbers in France during the World War and subsequently in Morocco and in Syria. They formed, however, inferior fighting material and the influence of the returned soldiers on their countrymen was not good. Other disturbing factors were the spread of alcoholism and of malaria and pulmonary disease among the people, leading to a marked decrease in the number of Hova and other races.

A brighter prospect was, however, shown in the marked attention paid by the French to education, and largely by this means the party among the natives attached to the French connection was built up. Primary schools were established in the villages, education was made compulsory between the ages of 8 and 14, and in all schools the children had to learn French. Nearly 100,000 children were attending school in 1925. The primary schools were supplemented by excellent regional schools—where lads were trained to become officials—and at Tananarivo and other towns there were means for higher education, including medical and agricultural schools. Another method by which the class of natives supporting the administration was increased was the lavish grant of decorations, including the Dragon of Annam, the Star of Anjouan and the Étoile Noire, as well as grades of Honneurs (12 classes), and medals such as the *mérite agricole*, the *mérite indigène* and *la médaille du travail*.

M. Marcel Olivier, who became governor-general in 1924, adopted a policy of decentralisation of the administration—greater local autonomy and the employment of more natives and in more responsible posts. While there was no form of popular Government economic and financial delegations existed and the plan of the administration was laid before them. The programme for 1925 laid special stress on the need to increase means of education, promote public health and to guide the natives, who after 30 years of French rule were taking larger views of life—and incidentally dressing largely in European fashion—upon the right road. Relations between the Protestant missionaries and the administration, after a period of strain, had reached a generally satisfactory position, and a larger share of the work was undertaken by French Evangelical societies. The Protestant missions had to meet, however, increasing and sustained efforts by the French Roman Catholic missions.

Economic Conditions.—Development of the natural resources of the island, if somewhat slow, was real. The chief products are rice, coffee, manioc, cattle and graphite. Cultivation is mainly by Malagasy; the number of French settlers on the land is small. In 1924 white colonists were cultivating 150,000 hectares; natives 1,110,000 hectares. Although as the result of a protective tariff the great bulk of trade is with France, about one-seventh is with Great Britain and much British capital is invested in the island. A feature of the commerce is that exports exceed imports both in quantity and value. In 1910 the exports amounted to 80,000,000 tons and imports to 61,000,000 tons; in 1924 exports were 302,000,000 tons and imports 90,000,000. As to value, the difference in the exchange rates of the franc and the increased cost of commodities prevent exact comparisons. The figures show the external trade (imports and exports) at 78,875,000 frs. in 1910 and 646,605,000 frs. in 1924.

Means of communication were greatly improved by harbour works and the building of roads and railways. By 1925 there were 1,500 m. of first-class roads and 540 m. of railway. The chief railway (240 m. long), connecting the port of Tamatave with Tananarivo, was opened in 1918. From this railway a branch line goes northward, and from Tananarivo a railway (107 m. long) opened in 1923 runs south to Antsirabé. There is a road but no railway to Majunga, the chief port on the west coast. Canals have been made and irrigation works carried out. Public buildings are handsome and solid, built with an eye to future developments.

Revenue is derived mainly from customs and a poll tax; expenditure was largely on the civil service. The budget of 1913, the last normal year before the World War, balanced at 32,000,000 frs.; in 1924 the budget was balanced at 100,000,000 frs.; in effect, taxation and receipts had not increased. It was then realised that if economic progress was not to be checked, a revision of taxation was essential.

BIBLIOGRAPHY.—The standard work on the island is the *Histoire physique, naturelle et politique de Madagascar* (1875, etc.), in many quarto volumes by Alfred Grandidier (1836–1921) founded on his exploration of Madagascar in 1865–70 and subsequent researches. Besides this great work, of which the latest volume appeared in 1917, Grandidier edited a *Collection des ouvrages anciens concernant Madagascar* (1903, etc.), of which vol. 9 was published in 1920; see also James Sibree, *A Naturalist in Madagascar* (1915) and *Fifty Years in Madagascar* (1924); G. Grandidier, *Le Myre de Vilers, Duchesne, Galliéni. Quarante années de l'histoire de Madagascar, 1880–1920* (1923); Jean Lefranc, "La Prosperité et les Besoins de Madagascar," in *Renseignements Coloniaux* (Dec. 1925); *Guide-Annuaire de Madagascar et Dépendances.* (F. R. C.)

MADRAS, India (*see* 17.291), capital of the Madras Presidency, and the third largest city of India, had a population of 526,911 in 1921, very largely Hindu. Madras is rapidly growing; the suburbs are extending, and many of the gardens in the city itself have been divided to provide further building sites. Work was in progress on a drainage system in 1924, and new waterworks have much improved the health of the city. There are large industries (12 mills employing 19,000 hands in 1924). The municipality was reorganised in 1919; there are 50 councillors, 41 elected and five appointed by Government, under an annually elected president. A fine council chamber has been erected behind the Government secretariat. Proposals for the improvement of the port, including a new quay, were made in 1924. The present harbour accommodates 15 vessels drawing up to 30 feet. The harbour works act as a breakwater, and since they were built the foreshore has considerably extended.

MADRAS, UNIVERSITY OF (*see* 27.775).—Since 1912 a small teaching staff has been attached to the university, and by an Act passed in 1923 the reorganisation of the university as a teaching and residential university was authorised. It still exercises control over the quality of the teaching in its constituent and affiliated colleges. In 1923 it received Rs. 45,200 under the will of Sir William Meyer, G.C.S.I. Fifty-three institutions are affiliated to it and recognised in degree courses in the faculties of arts and science, education, law, medicine, engineering, agriculture and Oriental learning.

MADRID (*see* 17.292), with a population of 813,991 in 1923, is the capital of Spain and the largest city. Old Madrid is disappearing, and many of the alleys east of the Palace have been pulled down, whilst a number of massive and pretentious buildings have recently been erected. A cathedral is being built on the site of an old church in the Calle de Baileu, and an Anglican church was consecrated in 1925. A large bull ring and stadium have been opened and an underground railway, the first in Spain, was finished in 1924. Owing to violent speeches in criticism of the Government made there, the Athenaeum Club was closed in 1924 and handed over to the production assembly, a newly formed economic body. In 1925 the Rockefeller Institute gave £85,000 for the establishment of an institute of physics and chemistry. It was decided in 1925 to remove the Hippodrome racecourse to allow of extending a housing scheme and the Paseo de la Castellana. The cost of living in Madrid is notably high.

MAETERLINCK, MAURICE (1862–), Belgian essayist and dramatist (*see* 17.298), presents a marked contrast in his later work published during the 20th century, after he settled in France, to his earlier works, published before he left Belgium. Several of his pre-War essays, collected in *The Buried Tem* (1902), *The Double Garden* (1909), *Life and Flowers* (1907), a more particularly his book on *Death* (1912), are inspired by reaction against his early mystic and fatalistic tendencies. T same contrast applies to the spirit of such plays as *Monna Van* (1909) and *Mary Magdalene* (1909), in which the action is co centrated in a few important scenes, more according to t Racinian than to the Shakespearian method.

The keen interest displayed by Maeterlinck in Shakespeari drama is nevertheless shown in his essay on King Lear, *Life a Flowers*, and in the translation of Macbeth (1910), written fo special performance given in the Abbey of Sainte Wandril *The Blue Bird* (1910), produced in 1911, still increased the pop larity of the Belgian writer in English-speaking countries. was followed by *The Betrothal* (1919), produced in London 1921. From the technical point of view, these fairy plays ma a return to the poet's early symbolism. During the War Ma terlinck wrote a war play dealing with the German occupati of Belgium: *The Burgomaster of Stilemonde* (1920) produced London by Sir J. Martin Harvey. *The Miracle of St. Antho* and *Mountain Paths* appeared in 1919, and two more plays in modern setting, *The Cloud that Lifted* and *The Power of the De* in 1923. Most of the works of Maurice Maeterlinck have be translated into English by A. Teixeira de Mattos. After t latter's death Bernard Miall and F. M. Atkinson undertook th work.

MAGNETISM (*see* 17.321). This subject may be studied fu ther in the articles CRYSTALLOGRAPHY, SPECTROSCOPY a TERRESTRIAL MAGNETISM.

Theories of Ferromagnetism.—Langevin's theory of parama netism has been extended by Weiss[1] to ferromagnetism by t introduction of a hypothetical molecular field H_2 proportion to the intensity of magnetisation I. This hypothetical force not necessarily magnetic. The relation between I and the ternal field H_1 is determined by the equations

$$I/I_0=\frac{\cosh a}{\sinh a}-\frac{1}{a}$$

$$a=\frac{MH}{RT},\ H=H_1+H_2,\ H_2=\lambda I,\ I_0=NM$$

where M is the moment of a magnetic atom, R the gas consta T the absolute temperature, λ a constant specific for the su stance, N the number of atoms per unit volume and I_0 t maximum possible intensity of magnetisation when all the ma netic atoms point in the same direction. These equations requ that in the absence of an external field ($H_1=0$) in general t intensity of magnetisation I will not be zero, but will have a de nite value given by eliminating a between the equations (1) a

$$I\ I_0=\frac{RT}{\lambda M I_0}a$$

and solving for I. This gives a single *intensity of permanent m netisation* which is stable, but disappears, and with it the fer magnetism, at a definite temperature, the *critical temperatu* given by $T_0=\lambda M I_0/3R$. If by means of this equation $R/\lambda M$ eliminated from (3) and the value of a thus obtained substitu in (1) the resulting equation is of the form

$$I/I_0=f(T/T_0)$$

where the function f is a purely algebraical function of the var ble T/T_0 the same for all substances. Thus if the intensity I permanent magnetisation is expressed as a fraction of the ma mum possible intensity of magnetisation I_0, and at the sa time the absolute temperature T is expressed as a fraction of critical temperature T_0, the theory leads to a characteristic eq tion for the intensity of permanent magnetisation (analogous the equation of state for a gas) which is identical for all ferrom netic substances. In the neighbourhood of the critical temperatu

$$(T-T_0)\,I=\frac{H_1T_0}{\lambda}$$

---

[1] P. Weiss, *Journal de Physique*, vol. 6, p. 661 (1907).

here I is the actual intensity of magnetisation in an external eld H_1, so that if H_1 is kept constant the I, T diagram will be rectangular hyperbola. Curie's measurements with iron afford n approximate confirmation of (5).

An alternative theory of ferromagnetism has been put forard by K. Honda and J. Okubo.[1] This theory is largely a mathe- iatical working out of the older ideas of Ewing, and is developed y the authors with a special view to the examples of iron, cobalt nd nickel, metals which are known to consist of a mass of cubi- il crystals. In the natural stable configuration the axes of the ementary magnets are aligned parallel to the axes of the cubic ystals. The actual magnetisation is determined by the dis- lacements under the influence of the external field and of the elds due to the neighbouring magnets. To account for temperaıre effects some spinning of the elements has to be invoked. he theory is made to give a good account of hysteresis and a umber of other phenomena, but the thermal side of it appears ıther forced.

Honda[2] states that the investigation of the binary alloys ırming a solid solution with each other shows that an alloy of paramagnetic with a ferromagnetic metal can be obtained which as a susceptibility of any value lying between those of the vo metals. Hence the two classes cannot be sharply distin- iished by the magnitude of the susceptibility, but each class an extreme member of a series of which the intermediate mem- ers can merge continuously into each other. In high fields the isparity between the intensities of magnetisation of manganese id iron is very much less than in fields of the order required to roduce saturation in the iron.

Ewing[3] has recently changed his model to meet some objec- ons applicable to the older form.

Ferromagnetic Crystals.—The magnetic properties of crystals e of fundamental importance, because metals such as iron con- st of a mass of interpenetrating crystals. Individual crystals pyrrhotine,[4] magnetite[5] and iron[6] have been investigated. yrrhotine (Fe_7S_8) is a hexagonal crystal. It is very difficult magnetise along the hexagonal axis. Of the two perpendicular es one is called the axis of easy magnetisation: the properties the direction of the other are similar to those along the hexag- ial axis, but the difficulty of magnetisation is not so great. The ırve of magnetisation (I, H curve) along the easy axis is re- arkably simple. If a correction is made for the demagnetising ırce and some little allowance for the material irregularities hich are almost inevitable in most minerals the diagram re- ices to a rectangle. If the specimen is unmagnetised at first remains unmagnetised till the value $H_c = 15{\cdot}4$ of the coercive eld is reached, when the intensity of magnetisation suddenly ımps to the saturation value $I_s = 47$ gauss, at which it stays for l values of H between -15.4 and $+\infty$. At $H = -15{\cdot}4$ the agnetisation suddenly reverses and stays at -47 gauss for alues of H between $-\infty$ and $+15{\cdot}4$. The constancy of the itensity of magnetisation is actually verified by the experi- ients directly without any corrections over a range of H from bout 700 to 11,000. If the direction of H does not lie along one the axes the direction of I no longer coincides with it. The itensity of permanent magnetisation has been found to agree ith the equation of state (4) above for magnetite from $-79°$ C. $+587°$ C., at which temperature the ferromagnetism disap- ears (T_0). Other substances show a fair correspondence with is requirement, but the agreement is not precise. The value the molecular field deduced by Webster from measurements ith single crystals of iron is not only very small compared with ie values obtained for pyrrhotine, but is much less than one- iousandth part of the values which have been got by other iethods for iron in bulk. This discrepancy would seem to call r serious investigation.

Magnetisation in Iron, Steel, etc., a Discontinuous Process.[7]—If the induced currents used to measure the change of induction are highly magnified by amplifiers, and sufficiently rapid detectors, such as oscillographs or telephones, employed, the I, H curve is found to consist of a succession of vertical and horizontal lines like steps. This is apparently due to the sudden magnetisation of successive elements of the material. These may be of considerable size, but it is doubtful if they are single crystals.

Paramagnetism.—Curie's law

$$kT = I_0^2/3R = C(\text{Curie's const.}) \qquad (6)$$

where k is the susceptibility, has numerous exceptions. Some of these are doubtless due to the universally present diamagnetism, to change of molecular aggregation and the like. In the case of paramagnetic solids the law requires a general amendment, Kamerlingh Onnes and his collaborators having shown that at temperatures down to about 80°K it should be replaced by

$$k(T + \Delta) = C \qquad (7)$$

where Δ is a specific constant for each substance. Equation (7) is sometimes known as Weiss's law. This law breaks down at the very lowest temperatures, the deviations shown by different substances becoming very complicated and individual in character.[8]

Gyromagnetic Effects.—In 1907 O. W. Richardson[9] showed that a delicately suspended rod should spin about the axis of magnetisation owing to the turning of the electron orbits during the act of magnetisation, and calculated the magnitude of the effects to be expected. If U_z and M_z are respectively angular momentum and magnetic moment per unit volume generated for any axis O_z, N,n numbers of electrons per unit volume, M,m masses of electrons and A,a the respective mean areal velocities about the axis O (capital letters referring to positive and small letters to negative electrons), then

$$U_2 = 2(N\ M\ A + n\ m\ a) \qquad (8)$$

and

$$M_2 = N\ E\ A + n\ e\ a \qquad (9)$$

If the positive parts of the atom are stationary the ratio U_2/M_2 reduces to 2m/e, and in any event it should be independent of the strength of the field. A search made at the time did not succeed in satisfactorily separating the effect from parasitic disturbances. It was first clearly established experimentally by Einstein and de Haas[10] in 1915, and has since been carefully measured by a number of experimenters[11] for iron, cobalt, nickel, Heusler alloys and magnetite. Meanwhile, in 1914, S. J. Barnett[12] had established the existence of a converse effect, *viz.*, the development of a magnetic field along the axis of revolution of a body when made to spin in a field-free space. The intrinsic magnetic field which would give rise to an equivalent magnetisation is calculated as

$$H = 2\frac{m}{e}\omega \qquad (10)$$

when only negative electron orbits are considered, ω being the angular velocity. The experiments show that both U_2/M_2 and H/ω are very close to m/e and not equal to 2m/e. This implies that the motions of the positively charged parts of the atom must be considered. If twice as many quanta of angular momentum are assigned to the electrons as to the nucleus this so-called *gyromagnetic anomaly* is accounted for.[13]

A third gyromagnetic effect, viz., a magnetic intensity produced by a revolving perpendicular magnetic field, is anticipated, but has not yet been established experimentally.[14]

The Magneton and Space Quantisation.—As a result of his observations of discontinuous changes in the apparent value of the Curie constant for magnetite, and for other reasons, Weiss[1] put forward the view that the magnetism of para- and ferromagnetic substances arose from a definite atom of magnetism. This *Weiss magneton* had a magnetic moment of $1{\cdot}85\times10^{-21}$ gauss × cm. The experimental evidence for the reality of this fundamental unit is very unconvincing. There is, however, according to the quantum theory (*q.v.*) a kind of fundamental unit of magnetic moment: the angular momentum of the electron orbits is limited to integral multiples of $h/2\pi$, h being Planck's constant, and we have seen above that the magnetic moment of such an orbit is proportional to its angular momentum. The value of this unit of magnetic moment, the "Bohr magneton" is $eh/4\pi m = 9{\cdot}23\times10^{-21}$ gauss × cm. Magnetic moment, however, is a vector quantity, so that the effect of compounding a number of such moments is more than a matter of mere addition. Thus no magnetic atom in the simple sense is to be anticipated. There should, however, be a tendency to certain discrete values owing to space quantisation.[2] In general if there is an axis of symmetry in the structure of the substance, or if such an axis is supplied by an external field, the quantum conditions require not only that the angular momenta about the polar axes of the orbits, but also their components about the axis of symmetry, should be integral multiples of $h/2\pi$. This double limitation restricts the orientation of the orbits to $m+1$ distinct planes where $mh/2\pi$ is the total angular momentum. The numbers of Weiss magnetons per atom have usually been deduced from the Curie constant C by the relation $C=\dfrac{n^2M^2}{R}\overline{\cos^2\theta}$ where M is the molar magneton (1123·5 gauss), R the molar gas constant, and θ the angle between the polar axis and the field, the average of $\cos^2\theta$ being taken on the assumption of equal probability for any direction. If, however, the averaging is confined to the discrete values just referred to, the number of Weiss magnetons which should correspond to the successive integral values of m from 0 to 6 are 0, 8·6, 14·1, 19·2, 24·4, 29·4, 34·4. There can be little doubt that the more reliable experimental values have a strong tendency to settle down at these numbers, and a plausible account can be given of such deviations as seem well established.[3] Gerlach and Stern[4] have shown that a fine beam of atoms when passed through a very inhomogeneous and powerful magnetic field is split into two in the case of Cu, Ag, and Au, into at least three in the case of Ni, and there is no effect in the case of Sn, Pb, and Fe. The splitting in the case of Cu, Ag, and Au, corresponds (the accuracy for Ag is about 10%) to a magnetic moment of $9{\cdot}23\times10^{-21}$. Thus this very important experiment establishes the reality at the same time both of space quantisation and the Bohr magneton. Some recently discovered changes with pressure in the susceptibility per unit mass of gases at low pressures are no doubt intimately connected with the phenomena discussed in this section.[5]

Magneto Optics.—Paschen and Back[6] have shown that in strong fields the complex Zeeman effects shown by multiple spectral lines in weak fields become simplified, the separations becoming integral multiples of the Lorentz-Larmor value. The change is a continuous function of the field strength. The magnetic response of multiplets as shown by their Zeeman effects is determined by their natural multiplicity, and there seems little doubt that this latter arises from the magnetic fields of the atoms. In an atom whose maximum permanent multiplicity is r and which is in an excited state such that its azimuthal quantum number is k, a good case can be made out that the maximum magnetic moment is equal to $(r+k-2)\dfrac{eh}{4\pi m}$. The magnetic moments so deduced show a reasonable agreement with those g from measurements of the paramagnetic susceptibilities of co responding ions. Each starts from zero, rises to a maximur and falls to zero again in traversing the successive elements the period from K through Fe to Cu, and there are other resen blances. One interpretation of the spectroscopic data requir that the magnetic moment of the atomic core should be twi as large as that calculated from the angular momentum, anomaly like that of the gyromagnetic anomaly already considere and capable of the same explanation.[7]

Permalloy.—H. D. Arnold and G. W. Elmen[8] describe a nicke iron alloy containing 78·5% Ni, which has remarkable magnet properties. The initial permeability is about 13,000, the ar of the hysteresis loop is $\frac{1}{16}$ that for soft iron and the maximu permeability 87,000 for B about 5,000. The saturation intensi of magnetisation is comparable with that for iron, and the allo approaches saturation in the earth's field.

MAGNETISM, TERRESTRIAL (*see* 17.353c). —Further deve opments occurring in various directions since 1909 in the stu of terrestrial magnetism are dealt with below.

Instruments.—The intercomparison of the magnetic instr ments of different countries has a recognised importance. Whi much was done before the World War by the Carnegie Instit tion of Washington, the comparisons between adjacent countrie which are specially desirable, have not been numerous. A dif culty increasingly realised is the uncertainty whether any ma netometer, even if never moved, can be considered invariab to the degree of accuracy usually aimed at, viz., 0·1′ in declin tion (*D*) and 1γ (0·00001 CGS unit) in horizontal force (*H*).

Trouble arises more particularly as regards the collimator magne moment of inertia and the "distribution constants" appearing the deflection formula $2mr^{-3}(1+Pr^{-2}+Qr^{-4})$. The use of a coil and electrical current promises increased accuracy in the measurement *H*, and coil magnetometers have been constructed in several cou tries, but the accuracy actually attained requires further investig tion. A coil instrument for the direct measurement of vertical for (*V*) would be of great value in high latitudes.

Surveys.—Observational work on land and sea has gone on c tinuously under the auspices of the Carnegie Institution of Washi ton, and many results have been published. Amongst recent s veys or resurveys which have been completed, there may be m tioned those of Belgium, the British Is., Japan and New Zeala There have also been numerous field observations in Canada, Fran Germany, India, the Scandinavian countries, Spain, the Uni States of America, and in a number of more restricted areas.

Eclipse Phenomena.—Special observations during solar eclip have been made at many places on a number of occasions, m especially by the Carnegie Institution of Washington, and a g many results have been published in *Terrestrial Magnetism.* consensus of opinion, however, has yet been reached, beyond the f that any systematic effect is certainly small. To demonstrate a sn systematic effect would require unusually quiet conditions ove period of days including the eclipse.

Sudden Commencements.—Another inquiry depending on operation has been into the simultaneity of the so-called "s den commencements" (S.Cs.) of magnetic storms. It has b suggested by S. Chapman and L. Rodés that the S.C. might associated with the engulfing of the earth in a jet or cloud of i emanating from the sun. If the ionic jet rotated with the su as Chapman suggests, its time to engulf the earth would be abo 30 seconds. If the ionic cloud were stationary, the process wo take some 6½ minutes. It seems fairly clear from the sev independent investigations which have been made that the di ence in the times of S.Cs., if any, is a question of seconds, of minutes.

Characterisation of Days.—Since 1906, an international sch has been in operation with its headquarters at De Bilt, Neth ands. Each co-operating station assigns to every day a “ charcter ” figure 0, 1 or 2, according as the day is quiet, moderately listurbed or highly disturbed. The arithmetic means of the igures so assigned are given in the annual De Bilt lists, so that ach day has an international character figure varying from ·0 to 2·0. Intercomparison of the character figures assigned at ifferent stations has confirmed the view that in ordinary latiudes disturbance is seldom if ever confined to one area.

The De Bilt character figures discriminate on the whole very atisfactorily between the days of the same month or season. But here is a natural tendency in the standard represented by 1 or 2 o vary according as the season is more or less quiet. To remove this ifficulty, F. Bidlingmaier suggested the use of “ magnetic activity ” efined as the mean value throughout the day of $^1/_8\pi(\alpha^2+\beta^2+\gamma^2)$, here α, β, γ represent the departures of the three rectangular agnetic components from their normal values. “ Activity ” in his sense exists and may be considerable on quiet days. Apart om the difficulty of assigning normal values, the amount of labour ntailed in the calculation of “ activity ” in the absence of some pecial mechanical means seems prohibitive. Various alternatives ave been proposed, including the daily ranges of one or all of the agnetic elements, the squares of the daily or hourly ranges, the ariation from day to day in the mean daily value of H, and the umber of intersections by the magnetic curve of a series of lines, arallel to the base line. In low latitudes disturbance is largely conned to H, and the character of the day may be fairly diagnosed on e H curve alone, but this is far from the case in high latitudes.

Twenty-seven-day Interval.—The existence of the De Bilt daily haracters has enabled the reality of a 27-day interval in magetic disturbance to be investigated without any possible prejuice. The phenomenon has been found to exist for quiet as well s for disturbed conditions. A day which follows a conspicuusly disturbed (or quiet) day after an interval of from 26 to 8 days has decidedly more than the average chance of being self a disturbed (or quiet) day.

Diurnal Variation.—The primary object of the international haracter scheme was the selection for each month of five quiet ays (commencing at Greenwich midnight) from which diurnal equalities of the magnetic elements should be calculated, ither additional to or in place of those derived from all days. f late years five international disturbed days a month have lso been selected at De Bilt, so that diurnal inequalities may be lculated from them as well. It has been found that in high latides the diurnal inequality is extremely sensitive to disturbance. his is illustrated by the vector diagrams (*see* 17.366 and 367) r the horizontal plane in fig. 1. They are for the equinoctial ason of 1912 at the two Antarctic stations Cape Evans (77°38′ uth, 166°24′ east) and Cape Denison (67°0′ south, 14°40′ st). The curves have been smoothed by the assumption that ey are true ellipses, with axes in and perpendicular to the eographical meridian. The hypothesis is certainly not much in rror, and it prevents the eye from being distracted by the irregurities inevitable in unsmoothed vector diagrams based on a mparatively few days. Starting from the centre in each case, e successive curves represent groups of days having for their ean international character figures 0·5, 0·15, 0·35, 0·65 and ·15. The curves are described in the direction of the arrows, e., anticlockwise.

Magnetic Poles.—Cape Evans and Cape Denison are on opposite sides of the south magnetic pole. Its position is not exctly known, somewhat conflicting results having been obtained y the different Antarctic expeditions. According to E. N. Webb the discussion of the results of the expedition led by Sir Dougs Mawson, the approximate position for the epoch 1912 was 1°·2 south, 150°·7 east. This is considerably to the northeast the positions assigned by the “ Southern Cross ” and “ Disvery ” expeditions (*see* 17.384). But all the expeditions agree placing the south magnetic pole near the direct line from Cape enison to Cape Evans. Accepting this as a fact, it may be own that a change of 4·5γ in the horizontal force vector is ughly equivalent to a shift of 1 km. in the position of the pole.

On this basis the curves of fig. 1 constitute independent estiates made at the two stations of the daily track of the south agnetic pole, on days of different international character, cording to the kilometre scale supplied. The subject has also been investigated for the north magnetic pole for the epoch 1904 by A. Graarud and N. Russeltvedt, using the observations of Amundsen's expedition. The principal base station, occupied by a magnetograph, Gjöahavn, had a dip of 89°17′, and in fixing the position of the pole use was made of four other stations with dips varying from 89°34′ to 89°52′. Thus the position found for the north magnetic pole in 1904, viz., 70°30′ north, 95°30′ west, cannot be much in error. This position differs by only 25′ of latitude and 1°16′ of longitude from that assigned in 1831 by James Ross (17.384), so there is no suggestion of rapid secular change.

On this basis Graarud and Russeltvedt calculated that a change of 3·2γ in the horizontal force vector answers to a shift of 1 km. in the position of the pole. The curve they give for its daily motion on the average day of 1904 is approximately elliptical, with minor and major axes respectively in and perpendicular to the geographical meridian. The extreme range from east to west is about 22 km., and that from north to south 13 kilometers. The curve, in short, is very similar to the Cape Denison curve for character 1·15, though slightly more elliptical. It is described, however, in the clockwise direction, as is natural for the northern hemisphere. The differences in sunspot frequencies, 42·0 in 1904 as against 3·6 in 1912, would naturally lead to a considerably larger amplitude in the earlier epoch.

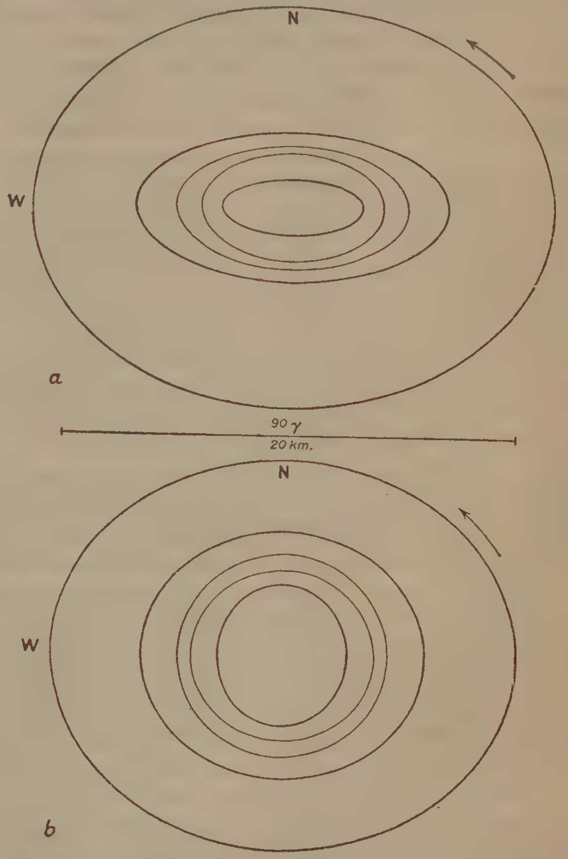

FIG. 1.—Vector Diagrams: (a) Cape Denison; (b) Cape Evans.

Variations of Disturbance with Latitude.—A comparison of the disturbances recorded in 1911–2 at the Scott Expedition's Antarctic station with those at observatories extending from Mauritius to Sitka, Alaska, showed a marked tendency for disturbance to be simultaneously great in high northern and southern latitudes, and to be less at intermediate stations, whether north or south of the equator. Again, comparison of auroras with magnetic character figures got out for individual hours, as well as for individual days, shows that an intimate relation exists between aurora and magnetic disturbance. While long accepted as true of large magnetic storms and aurora in countries where both phenomena are rare, this seems also true in the case of bright aurora in high latitudes. In the case of faint non-fluctuating aurora, magnetic conditions seem often practically unaffected. Faint aurora, in fact, seems the rule rather than the exception in high latitudes under conditions favourable to its visibility.

Theory of the Regular Diurnal Variation.—The derivation of the diurnal variation from a potential has been further considered. Assuming the derivation possible, the constants occurring in the potential have been calculated by W. van Bemmelen, S. Chapman, F. Bidlingmaier and J. Bartels. A. van Vleuten, who has examined the hypothesis critically, especially as applicable to quiet-day phenomena, has, however, concluded that the balance of evidence is against it. A difficulty in the way of any general theory of the diurnal variation is the varied influence of disturbance. This influence not merely differs at different places, but is not the same for the different elements. It also varies with the season of the year, and is not the same at the same season of different years.

General Theory.—These various phenomena—the synchronous occurrence of magnetic disturbance in different parts of the earth, its special development in high latitudes, the enhancement of the regular diurnal variation during disturbance, the association of disturbance with aurora, and the 27-day interval —all accord *in a general way* with the theory pretty generally held that magnetic disturbance and aurora are both due to the emission from the sun of some species of electrical radiation. The nature of this radiation, whether β or α rays, has been discussed more especially by Kr. Birkeland, C. Störmer and L. Vegard. Difficulties, especially the scattering to be expected from the mutual repulsion of ions, if all of one sign, have been discussed by A. Schuster, S. Chapman and F. A. Lindemann.

When approaching the earth, ions of either sign would naturally spiral round the lines of magnetic force, and so be concentrated in high latitudes. But for ordinary α or β rays the approach to the magnetic poles should be closer than auroral phenomena suggest. To explain the occurrence of aurora in comparatively low latitudes, Störmer has suggested the existence of a ring of ions in the magnetic equator, but no proof of its existence has been advanced. The presence of ions would naturally increase the electrical conductivity, thus enhancing the amplitude of the regular diurnal variation of the magnetic elements, supposing that due (as is generally believed) to electrical currents in the upper atmosphere. The fact that disturbance enhances the diurnal inequality relatively more in winter than in summer would follow naturally from the very probable hypothesis that ordinary solar radiation itself increases the conductivity of the atmosphere. In high latitudes we may suppose that in winter the electrical currents associated with aurora play the part which in summer is largely played by direct solar radiation.

In the simplified mathematical theory of aurora and magnetic disturbance developed by C. Störmer, the earth is treated as magnetised as it would be if only the first order Gaussian harmonic existed. Everything is then symmetrical round the axis of the first harmonic, whose north end according to J. C. Adams was in 1880 at 78° 24′ north and 68° 4′ west, but moving west through about 0°·1 per annum.

In a theory of magnetic storms, S. Chapman also assumes symmetry round an axis, regarded as magnetic latitude 90°. He has derived mean results from 40 storms recorded at 12 stations arranged in five groups according to magnetic latitude. Confining himself to storms having an S. C., he regards the "general storm" phenomena, *i.e.*, the phenomena not dependent on local time, as determined by the "storm time," or time elapsed since the S. C. The phenomena varying with local time, he regards as composed of the ordinary diurnal variation + a "local storm variation," determined like the general storm phenomena by the magnetic latitude. He discusses the electrical current systems supposed to "flow in more or less horizontal strata in the upper atmosphere" to which the magnetic changes he has arrived at may be ultimately ascribed. "The external currents will of course be accompanied by corresponding induced currents within the earth which will modify their effects." Taking what he considered an average storm, Chapman calculated that it called for the expenditure of energy at the rate of about 2×10^{18} ergs per second for 15 hours.

To many minds, theoretical researches of this kind are fascinating, but deductions from them, until confirmed by direct observation, are just as hypothetical as the theories themselves. Magnetic phenomena are much less simple than theories such as Störmer's and Chapman's suggest. The complete Gaussian analysis indicates in reality a considerable departure from symmetry round an axis. High latitudes, moreover, were practically unrepresented in the data used for calculating the Gaussian constants, while the asymmetry in the positions of the two magnetic poles suggests that the results of the analysis may depart most from truth in the very regions where aurora and magneti storms are most developed. The individual aurora or magneti storm shows no approach to symmetry round a magnetic axis The magnetic disturbance on a given occasion is of very differen amplitude at stations having the same magnetic latitude. Eve when there is a recognisable S. C. the sequence of events at given station varies much on different occasions.

In low latitudes the S. C. is a change mainly in *H*, almost invariably a rise. In higher latitudes it is usually oscillatory, and may be large in all the elements. The duration of the enhanced value i *H* following the S. C. is sometimes a few minutes, sometimes several hours. Following the enhancement there is generally a pronounced fall, bringing *H* well below its normal value. But the recovery from this depression may set in after a few hours and proceed almost uninterruptedly, a return to comparatively quiet conditions occurring within 12 hours, or there may be a succession of irregular movements, highly disturbed conditions lasting for one or two days The superposition following "storm time" of unsorted disturbanc curves may give us a storm such as never existed. Comparison o magnetic curves from Kew, Stoneyhurst, Eskdalemuir and Lerwick has shown that while the amplitude of magnetic disturbance in th British Is. almost invariably increases with magnetic latitude, th rate of increase differs widely on different occasions. On specia occasions there may be very large rapid movements in Lerwick which are hardly represented in the south of England. The averag intensity even of magnetic disturbance must be largely determined b other things than the magnetic latitude, as defined by Chapman Agincourt (Toronto) and Kew are of nearly the same "magneti latitude," but disturbance, at least in 1911–2, was almost invariabl much larger at Agincourt than at Kew.

Chapman's estimate of the energy of a magnetic storm is certainl much less improbable than the enormously higher estimate made i 1892 by Lord Kelvin on the hypothesis of direct magnetic actio between the sun and the earth, but it depends fundamentally o several assumptions, the degree of probability of which is at presen entirely a matter of opinion.

MAHAFFY, SIR JOHN PENTLAND (1839–1919), Irish classic scholar (*see* 17.394), became vice-provost of Trinity Colleg Dublin, in 1913 and provost in 1914. In recognition of the ser ices of the college during the World War, he was in 1918 ma a G.B.E. From 1911 to 1916 he was president of the Royal Iris Academy. He died April 30 1919.

MAHAN, ALFRED THAYER (1840–1914), American nav officer and historian (*see* 17.394), died in Washington, D. Dec. 1 1914. His later works included *Naval Strategy Compar and Contrasted with the Principles of Military Operations on La*

1911); *Armaments and Arbitration* (1912) and *The Major)perations of the Navies in the War of American Independence* 1913).

See C. Carlisle Taylor, *The Life of Admiral Mahan* (1921).

MAH-JONGG.—This is a Chinese game, for four players, vhich was introduced into Europe and America about 1923. The ;ame is played with a number of pieces known as tiles. There are 44 tiles in all, comprising four "flowers," four "seasons," four vhite, four red and four green "dragons"; four each of north outh, east and west "winds"; and three "suits," namely characters," "bamboos" and "circles." Each suit consists of 6 tiles, made up of four lots numbered one to nine inclusive.

Each player plays independently, and the procedure is briefly s follows: The tiles are arranged in pairs face downwards in our sides of a square, each side, or wall, containing 17 pairs. he eight extra tiles are left in the middle of the table to be taken p by any player who draws a "flower" or a "season." The ank is allotted by a throw of dice, and the highest throw fixes lso the point at which the wall shall be opened. Each player is llotted a wind, the banker taking the east wind. Each player, tarting with the banker and working anti-clockwise, draws four iles at a time from the wall till each has drawn 12, then the anker draws one extra tile. Each player's object is to make a omplete hand of twos, threes, or fours of a kind, *e.g.*, three sixes f "characters" and sequences; or four, five and six of "bamboos."

The actual play commences when the banker discards a tile, lacing it face upwards on the table. Each player, playing in rder clockwise, then draws a tile from the wall and discards one rom his hand. Should he draw a "flower" or a "season" he xposes it and draws one of the eight extra tiles from the centre f the table. If a player discards a tile of which another player lready has two, such other player may cry "pung" and take the iscarded tile, at once exposing the three tiles on the table. The layers on the left of the discarder, by crying "chow," may imilarly take a discard to complete a sequence of three. A pung r a chow does not affect the order of drawing, nor does it count s a draw. A player punging a tile takes it in preference to a layer wishing to chow it. Finally, a player requiring a discarded ile to make his hand complete cries mah-jongg, and takes the ile in preference to all other claimants. A player can go mah-ongg either by claiming a discard, or by drawing a tile in the rdinary way, but such tile must complete his hand without urther discarding on his part. The hand finishes as soon as one layer goes mah-jongg

The scoring is somewhat complicated, and various conditions in hand entitle the player to double his score. The mah-jongg hand paid in full by all the others except the banker, who pays him ouble. If he is himself the banker, he is paid double by all. he other players pay differences to each other, the banker aying or being paid double as the case may be. The bank asses anti-clockwise for the following hand, unless the banker vent mah-jongg, when it remains with him.

MAHLER, GUSTAV (1860–1911), Austrian composer and conuctor, was born at Kalischt, Bohemia, July 7 1860. From 1885 nwards he conducted in Prague, Budapest, Hamburg and ondon, becoming director of the Vienna Opera in 1897. By nremitting zeal and tireless enthusiasm he brought the Vienese opera to a high state of perfection, but the strenuous ork which he exacted from all earned him the name of "the yrant" and made him many enemies, and in 1907 he was obliged o resign his post. He immediately received the offer of a onductorship in America, which he visited for three seasons, eturning to Vienna in 1911, where he died on May 18. Mahler eflected to some extent in his works the classical tradition herited from Schubert and Bruckner. In addition to his songs nd chamber music, he wrote no fewer than nine symphonies, lanned on a gigantic scale for an orchestra nearly doubled in trength. These lengthy works, though rarely performed, have evertheless had a certain vogue in Holland, chiefly owing to he zeal of the eminent conductor Mengelberg. See R. Specht, *ustav Mahler*, etc. (1913); P. Stefan, *Gustav Mahler, a Study of his Personality and Work* (1913); G. Adler, *Gustav Mahler* (1916); P. Bekker, *Gustav Mahler's Sinfonien* (1921).

MAHOMMED V. (MEHMED) (1844–1918), Sultan of Turkey, was born at Topqāpu Nov. 3 1844, a younger son of the Sultan 'Abdul Mejid (1823–1861). He led a quiet and retiring life, and suffered at times considerably from the jealousy and suspicion of his elder brother, the Sultan 'Abdul Hamid II. On the deposition of 'Abdul Hamid he was invested as caliph (May 10 1909). He was, for the most part, merely a tool in the hands of the committee of union and progress and, though he was supposed to dislike the pro-German policy of Enver Pasha, he was unable to take any effective steps to oppose him. He died at Yildiz July 3 1918, and was succeeded by his brother Vahid-ed-Din (b. 1861) as MAHOMMED VI., the latter resigned in Nov. 1922 and died at San Remo May 15 1926.

MAHOMMEDANISM (*see* 17.399).—Of all the great faiths that have been accepted by large masses of the human race, Islam is one of the most historical. For the details of the life of the Founder the reader is referred to the article MAHOMET. The faith he preached is Islam, *i.e.*, resignation, submission to an Almighty Will. It teaches abstinence from drink, personal cleanliness, and abhorrence of evil, and, above all, the value of human life. The world is a well-ordered creation, regulated and guided by a Supreme Intelligence overshadowing the universe, since "Everything is pledged to its own time." Yet the human will is free to work for its own salvation. The sympathy of Mahomet was universal, and he invoked the mercy of the Creator "on all living beings." He pronounced the saving of one human life to be tantamount to the saving of humanity.

His social conception was essentially constructive, not disintegrating. In his most exalted mood the Teacher never overlooked the sanctity of family life. To him the service of humanity was the highest act of devotion. His call to the Faithful was not to forsake those to whom they owed a duty; but in the performance of that duty to earn merit and reward. Monasticism was disapproved of as contrary to nature. Children were a trust from God, to be brought up in tenderness and affection; parents were to be respected and loved. The circle of duty embraced in its fold "kindred and neighbours, and the lowly and poor."

The Koran.—The Koran has, on mistaken analogy, been sometimes called the Mahommedan Bible. The Old Testament is a record of ancient Israelite traditions which have, in one form or another, become the common property of the three Semitic faiths that now rule over the consciences of masses of mankind. All these traditions have passed through numbers of hands and bear evident traces of revision and editing. The synoptic Gospels, which form the outstanding feature of the New Testament, were not compiled, at least in the shape in which they have come down, until long after the events they purport to record.

The Koran, as a human document, stands on a totally different footing. As such it is *sui generis*. It is a record of the outpourings of one single human heart to whom the Soul of the Universe had spoken, and it has escaped revision. It prescribes religious duties in precise terms. Since men owe gratitude to the Creator for His manifold blessings, he should be glorified daily at stated times, so that there may be no neglect in the performance of His Worship. Five times a day devotions are offered to the Lord of Creation. Man must approach Him in purity of heart and body; and the practice of the Prophet has consecrated the mode of physical lustration and the cleansing of the heart.

Abstinence was also made a part of the religious law. Every able-bodied man or woman is required to abstain from food and drink from sunrise to sunset for one lunar month. The only exceptions to this rule are students and soldiers engaged in defence of their religion or country, and invalids male and female. Charity was incorporated as a part of religion and every person possessed of a sufficiency was required to give a certain part of his income for the support of the indigent.

Social Regulations.—The status of women was raised beyond any known in contemporaneous history. Far from degrading women, the legislation of Mahomet raised her in the social scale. "Paradise," it was declared, "is at the feet of the mother." In his last sermon the Prophet enjoined his followers thus:—" Ye people, ye have rights over your wives and they have rights over you. Treat your wives with kindness and love. Verily you have taken them on the security of God."

The unrestrained polygamy of pagan times was drastically cut down; and the number of wives was limited to four and subjected to a condition which rendered it impossible under civilised conditions to practice polygamy without infraction of the rule. Owing to this condition in fairly-advanced Moslem communities polygamy has been much reduced.

Human chattelhood was forbidden; bondage was permitted only in the case of prisoners taken in " lawful " warfare in defence of religion; stringent rules were prescribed for the treatment of the unfortunate beings held in bondage; the child was not to be separated from its parents; no husband from his wife or one relative from another; and if a bondswoman bore a child to her master, she became at once a free woman and the child took the status of legitimate issue. The enfranchisement of people held in bond was an act of supreme merit with the Lord. Moslems were enjoined to " feed their slaves as they feed themselves, and clothe them with the stuff they wear."

The Sects of Islam

Islam, like Christianity, has been rent by schismatic strife and sectarian bitterness. The bulk of the Moslem population belong to the Sunni persuasion. Shiahs are found chiefly in Persia, but also in India. The Sunnis and the Shiahs differ greatly in their religious conceptions and doctrinal practices, and the difference extends from doctrines into the region of law, *e.g.*, the Shiah law of succession does not recognise agnacy, and daughters' children are not excluded by an uncle's son. Again, while the Sunni is enjoined to offer the prescribed prayers " congregationally " in a mosque, the Shiah may offer his orisons individually in the privacy of his house.

The principal divisions of the Sunni sect are mainly legal, according as the interpretations of the Hanafite, the Shafiite, the Maliki or the Hanbalite school are followed. Among the Shiahs, also, great jurists flourished who, deriving their inspiration from the medinite school, were liberal in their conceptions.

Wahhabiism.—Conformity was maintained in the Sunni community until the middle of the 18th century, when there arose a man in Central Arabia, named ʿAbdul Wahhab, who revived the Khariji cult in all its pristine Calvinistic bigotry. He welded the Arab tribes into a composite force and established his authority from the shores of the Persian Gulf to the Red Sea. The Wahhabis, as his followers have ever since been called, captured Mecca and Medīna, from which they were driven out by the forces of Ibrahim Pasha, the son of Mehemed Ali, the founder of the present dynasty which rules over Egypt.

Ibn Saʿud, the present chief of the Wahhabis of Nejd, emulated the achievements of his forbears by capturing again the Holy Cities from the hands of King Husain. In 1912 he had begun the formation of the new organisation of the Wahhabis under the name of Ikhwan or " brethren," and established colonies of them in various parts of Arabia, with the design that the settlers should sink their tribal rivalries in a communal religious life.

Senusis.—A religious movement closely connected with Wahhabiism was that of the Senusis, but though its teachings were practically identical, its organisation followed the usual lines of religious orders in the Mahommedan world. Founded in 1837, this order has achieved an immense expansion not only over the whole of North Africa from Egypt to Morocco and far to the south, but also in Mesopotamia and the Malay Archipelago. The order has been zealous in proselytising and has made many converts to Islam. Its activities were for a number of years a source of anxiety to the French as they appeared to be directed against the extension of European influence in Africa, and it took up arms against the Italians after the occupation of Tripoli in 1911, but in recent years has entered into friendly relations with them.

Shiahism.—Shiahism had no such auxiliary as Sunnism possessed in the form of organised political power to prevent its being rent with heresies, and consequently it has been distracted by constant schisms. Some owed their origin to dynastic rivalry; others to survivals of earlier cults in Western Asia.

Imamis.—The followers of the twelve Imams of the House of the Prophet (Ahl-ul-Bait) are commonly called Imamis. Ismail, the founder of the Safavid dynasty, made this branch of Shiahism the state religion of Persia, which character it has retained ever since. The Shiahs in India are also chiefly Imamis.

Zaidis.—The Zaidis are the followers of Zaid, a grandson of Husain, the martyr of Kerbalā. They differ from the general body of the Shiahs regarding the title of Abu Bakr, Omar and Othman to the Caliphate, and agree with the Sunnis on this point. The Zaidis are still found in the Yemen and North West Africa. The Zaidi Imam, Yahya, has recently consolidated his authority in Northern Yemen and is reported to be a ruler of great capacity.

Ismailis.—The Ismailis derive their name from Ismail, th eldest son of the Imam Jaʿfar as-Sadik, who pre-deceased his father. They hold that on the death of the Imam the religious headship devolved on Ismail's son Mohammed, whom they call al-Maktum (the " unrevealed " Imam), and not on his uncl Jaʿfar's second son, Musa al-Kazim, as believed by other Shiahs. Al-Maktum was, according to the Ismailis, succeeded by Ja'far al-Musaddak whose son, Mohammed al-Habib, was th last of the " unrevealed " Imams. The Ismailis achieved politica importance with the foundation of the Fatimid dynasty in North Africa in 909 and after the conquest of Egypt in 969 the Fatimids ruled over North Africa and Egypt for two centuries. In th realm of thought one of the most remarkable manifestations o Ismaili speculation is found in the treatises of the Ikhwan uṣ-Saf (the Brethren of Purity), a society of rationalists towards th close of the 10th century; they taught that individual souls ar part of the world soul, to which they return after the death o the body. Through various stages of emanation the whole universe proceeds from God, and the re-union of the soul with Go is effected through the reversal of this process and the purification of the soul from all grosser elements by asceticism, spiritua exercises and philosophy.

Assassins and Druses.—Two sects more permanent and mor highly organised, the Assassins and the Druses, still survive a offshoots of the Ismaili movement. The Assassins in 1090 established themselves in the fortress of Alamut, in the north of Persi and later in a number of other strongholds in that country an in Syria, and thence carried on an active propaganda, and thei devoted followers did not hesitate at the risk of their own liv to use the dagger to remove political opponents. Their politic independence was brought to an end by the Mongols, who destroyed most of their castles in the 13th century; but this sec still survives in a very altered form under the headship of H.H. th Aga Khan, whose followers in India number more than 127,00 in addition to adherents scattered throughout Syria, Persi Central Asia and East Africa. His followers in India are know as Khojas and a large number of them are descended from Hind converts and still adhere, in most important particulars, to th Hindu rules of succession.

A still more heterodox offshoot of the Ismaili sect is the community of the Druses, living in the Lebanon and the Anti-Leban and in the mountains of Hauran. They hold that God becom incarnate in man in every age, and that Hakim, the sixth Cali of the Fatimid dynasty in Egypt (996–1020), was the last incarnation of God; they believe that Hakim did not die and th he is only absent from human sight and will one day manif himself again.

Babis and Bahais.—Another outgrowth from Shiahism w the Babi, followed by the Bahai movement, but in their latitudinarianism they have so far diverged from any orthodox form Islam, that it is very doubtful whether they can properly reckoned among Mahommedan movements. The Bahais ha carried on an active propaganda in America and in certain par of Europe, and have drifted further and further from the Islan source from which they originally sprang.

The Ahmadiyya Sect.—In the year 1879 the founder of a ne religious movement, named Mirza Ghulam Ahmad, began reach in the village of Qadian in the province of the Punjab, ndia. He claimed to be not only the promised Mahdi but also he promised Messiah—personages generally held to be distinct ordinary Mahommedan theology. Another modification he in- roduced into Islamic doctrine had reference to the death of esus; the commonly-accepted belief maintains that Jesus was aken by God alive into heaven, while a phantom was crucified his place; in oppositon to this he declared that Jesus was actu- lly crucified, but was taken down from the cross while still alive y his disciples, was healed of his wounds and afterwards made is way into Kashmīr, where he finally died, his tomb being till in existence in the city of Srīnagar. Having thus removed he ground for any expectation of the second coming of Jesus om heaven to earth, he explained that he himself was the Messi- h, not as being an incarnation of Jesus (for he rejected the doc- rine of transmigration), but as having come in the likeness of esus—being Jesus for this generation just as John the Baptist as Elijah, because he came in the spirit and power of Elijah.

In proof that he had come in the spirit and power of Jesus, irza Ghulam Ahmad adduced the likeness of his own char- cter and personality to that of Jesus, his gentleness of spirit, e peaceful character of his teaching, his miracles and the ap- ropriateness of his teaching to the need of the age. In har- ony with this pacific claim, he expounded the doctrine of Jihad sually interpreted as meaning war against unbelievers) as a riving after righteousness. Mirza Ghulam Ahmad died in 908, and a few years after his death his followers split into two rties, one having its headquarters in Qadian, and the other in ahore. Both these sections of the community succeeded in en- sting the services of devoted, self-sacrificing men, who are nceasingly active as propagandists, controversialists and pam- hleteers. They control an extensive missionary activity, not nly in India, West Africa, Mauritius and Java (where their forts are mainly directed towards persuading their co-religion- ts to join the Ahmadiyya sect), but also in Berlin, Chicago and ondon. Their missionaries have devoted special efforts to win- ing European converts and have achieved a considerable meas- re of success. In their literature they give such a presentation Islam as they consider calculated to attract persons who have ceived an education on modern lines, and thus not only attract on-Moslems and rebut the attacks made on Islam by Christian ontroversialists, but win back to the faith Moslems who have me under agnostic or rationalist influences.

Modern Literature.—Indeed it has been characteristic of much the theological literature of the Mahommedan world for the st few decades, to adopt an apologetic tone and to shake off ose special features which have exposed it to hostile criticism; us polygamy, slavery and intolerance are declared to receive o sanction from the Koran, as rightly interpreted; in Islam the conciliation of religion and science is effected, and the demands the modern spirit of enlightenment are satisfied. Of such odernist literature there has been a considerable output, espe- ally in Egypt and India; it naturally appeals most to those aders who have come under European influences, and excites nsiderable opposition among more conservative orthodox rcles, who remain loyal to the traditional schools of thought s enumerated above) and resent the rejection of traditional, ediaeval theology by the modern thinkers. The older sects ntinue to flourish, and the new thought has not yet attempted organise itself on sectarian lines and has thus remained largely matter of individual opinion.

This lack of sectarian development is possibly in great meas- re due to the absorbing attraction that political problems dur- g recent years have exercised upon the Mahommedan world. nxiety as to the fate of Turkey after the Armistice, the with- awal of the Holy Cities from the control of the Caliph and the cupation of Jerusalem by unbelievers, the separation of the ltanate from the Caliphate (in 1922) and the abolition of the aliphate altogether (in 1924) were circumstances that profound- stirred the minds of pious Moslems all the world over and did t create an atmosphere favourable to the calm consideration purely dogmatic problems. Moreover in many Mahommedan countries some form of nationalism obscured the larger vision of a united Islamic world; in Turkey it took the extreme form of Pan-Turanianism, or Pan-Turkism, which aimed at the union of all sections of the Turkish race in one vast confederacy and sought to purge the national life from all foreign admixture, in language, literature and political institutions; in India nationalist feeling prompted the Hindu-Moslem Entente and gave birth to the oft-repeated sentiment, "I am an Indian first, and a Moslem afterwards"; among the Mahommedan populations of Russia the formation of Soviet Socialist Republics has evoked nationalistic movements which have temporarily thrust purely religious interests into the background; Bolshevik propaganda has also met with a response among the Mahommedans of Java.

But Islam is so closely bound up with every aspect of the life of a Mahommedan people that even a purely nationalist political movement may react strongly on the religious life. This has been notably the case in Turkey, where the Government, besides abolishing the Caliphate, has confiscated the religious endowments and suppressed the religious orders; polygamy has practically been made illegal; the date of Ramadan has been fixed in accordance with astronomical science instead of being made dependent on reports that the moon has been seen (as has been the immemorial custom in the Islamic world); and the discontinuance of the wearing of the veil by women and the adoption of hats by men, are typical of a changed attitude towards the established usages of Mahommedan society. The breach with the past has been nowhere so violent as in Turkey, but throughout the whole Mahommedan world there are indications of a changed attitude towards religious questions. The old orthodoxy still holds the allegiance of the masses, as well as many of the educated, but others, especially those whose education has brought them under European influences, are seeking a re-statement of their religion, more in harmony with their general outlook upon life. To those that seek a solution in the realisation of some nationalist ideal, there remains little save a sentimental attachment to Islam, while they deprive it of any control over law and social organisation; the reformers, on the other hand, claim for the precepts of Islam control over all the relations of human life, but seek to restore it to its primitive simplicity, believing that thus it can be brought into harmony with modern thought and modern conditions.

MAINE (*see* 17.434).—The population of the state in 1920 was 768,014, in 1910 742,371, an increase of only 3·5%, as compared with 14·9% for the United States in the same period and 6·9% for Maine in the previous decade. There was a significant increase in urban population. The proportion living in places of 2,500 or more was 33·5% in 1900, 35·3% in 1910, and 39% in 1920. In 1910 the rural population was 480,123; in 1920, 468,445. The only one of the 16 counties showing a marked increase in rural population was Aroostook, which is one of the richest farming regions of New England.

The principal cities of the state, with their population of 1920 and 1910 and rate of increase, were as follows:—

City	1920	1910	Increase per cent
Portland . . .	69,272	58,571	18·3
Lewiston . . .	31,791	26,247	21·1
Bangor . . .	25,978	24,803	4·7
Biddeford . . .	18,008	17,079	5·4
Auburn . . .	16,985	15,064	12·8
Bath	14,731	9,396	56·8
Augusta . . .	14,114	13,211	6·8
Waterville . . .	13,351	11,458	16·5

Agriculture.—In Maine there were in 1920, 48,227 farms, valued with equipment at $250,000,000. Although the number of farms has decreased since 1910, the value of farm land has greatly increased; and in certain fields such as poultry there have been gains. The poultry co-operative marketing is being successfully conducted; and in other branches of agriculture newer methods of marketing are making up for decreased acreage. Maine's potato crop in 1924 totalled 41,475,000 bushels. Fifty-five per cent of all certified seed potatoes in the United States was grown in Maine in 1924. Figures for that year show 305 bu. of potatoes per ac.; 42 bu. of corn; 26 bu. of wheat; 37 bu. of oats. One of the chief agricultural industries is the production of sweet corn for canning. In 1924, 38,030 tons of corn were cut. Lately canned green peas are coming into equal popularity. In Washington county blueberry production is one of the staple industries. Maine's annual blueberry crop is valued at a million dollars. Hay still leads other crops: 1,432,000 tons in 1924 as against 1,326,289 tons in 1919. Maine has a very low percentage of mortgaged farms; in 1924, 67·5% were free from mortgage indebtedness as against the national average of 52%. Ninety-six per cent of Maine farms are owned by men who operate them. It is estimated that about one-third of the people living in Maine are engaged in, or are supported by, agriculture. But over one-half of the foodstuffs come from outside the borders of the state—a situation that has led to efforts encouraging the use of markets and the development in Maine of agricultural independence.

Forestry and Lumber.—During the past few years much attention has been given to afforestation. Nearly three-fourths the area of the state, 15,000,000 ac., is forest land. Very recently attention has been called to the abundance of hard wood in the Maine forests, a fact that had been overlooked in the unparalleled consumption of pulp wood. The total stand of timber, spruce and fir is estimated at 25,500,000,000 ft.; pine, 5,060,000,000 ft.; cedar, 2,780,000,000 ft.; hemlock, 880,000,000 ft.; hardwoods, 5,000,000,000 feet. The annual cut of lumber is approximately 1,000,000,000 feet. Figured on the basis of population Maine's forest lands amounted in 1925 to 19·5 ac. *per capita*, a ratio exceeding those of all other states east of the Rockies, except Florida.

Shipbuilding and Fisheries.—The shipbuilding industry was stimulated during the World War to a remarkable activity, which, however, subsided in the years immediately following. Bath, the chief shipbuilding city, attained, during the height of this boom, to a population of 15,000.

Manufactures.—In total value of products, paper and wood pulp manufacturing ranks first among Maine industries; cotton goods are second; boots and shoes third; and woollen goods fourth, followed by lumber and timber products. Maine leads all the states in the production of wood pulp; and Old Town leads the country in the manufacture of canoes. There is still much undeveloped water-power; the U.S. Geological Survey credits Maine rivers with a potential maximum of 1,300,000 electrical horse-power, of which 700,000 is undeveloped. The state still refuses to allow the exportation out of the state of water-power; but there are indications that this policy does not meet with as much popular support as it did a few years ago.

Administration and Finance.—Since 1910 there have been adopted 13 amendments to the state constitution, the total number of amendments numbering 47 in 1925. Of amendments adopted since 1920 the two most important provided for a bond issue of $3,000,000 for a bonus to Maine soldiers and sailors in the World War, and for voting by mail. Maine is fast becoming the summer playground of the country. It has been conservatively estimated that nearly a million tourists visit Maine annually; and the summer visitors furnish an important element in the business life of the state. There are 165 summer camps for boys and girls, with an attendance exceeding 7,500. The recreational advantages of the state were emphasised in 1925 by Gov. Brewster in his inaugural address; and an elaborate programme of publicity, based upon the examples of California and Florida, was undertaken under the auspices of the state and with funds provided in part by appropriations granted by the state.

Education.—During the decade 1915–25 much progress was made, particularly in the rural schools. A well-arranged programme providing for school buildings of modern construction was being carried out in cities and towns; and in rural communities the old-fashioned type of isolated, single school buildings was giving way to consolidated buildings, transportation being furnished to pupils from remote homes. In 1925 the total enrolment of pupils was 163,106, as against 154,604 in 1920; 132,853 were enrolled in the elementary schools, and 30,253 in the high schools and academies. Of the farm population of high-school ages, 49·3% was enrolled in high schools, as compared with 42·3% of the non-farm population. Maine claims to have the highest percentage in the country of farm boys and girls attending high schools. The state dept. of education also put into operation a well-devised plan for the gradual elimination of illiteracy through evening schools and adult classes. There were about 1,400 students in the six normal schools, and about 3,300 students in the state university and Bates, Bowdoin and Colby colleges.

History.—In 1911, for the first time since the Civil War, Maine had a Democratic governor, Frederick W. Plaisted, and two Democratic senators, Charles F. Johnson, of Waterville, and Obadiah Gardner, of Rockland. In 1912 Woodrow Wilson won the electoral vote of Maine by reason of the split in the Republican ranks. But in 1916 the split was healed and Maine in every election thereafter ran true to form as a Republican state. The consolidation of various newspapers with other changes in ownership left the minority party practically with no press. The chief contests consequently were in the primaries for the Republican nominations. In 1924 the choice for governor between Frank Farrington, of Augusta, and Ralph O. Brewster, of Portland, was so close that for some weeks the result was in doubt, a recount held by the governor and council finally giving the nomination to the latter. In view of Federal legislation on prohibition and woman suffrage it is interesting to recall that in Sept. 1911 the state of Neal Dow voted to retain the prohibitory amendment to the constitution by the extraordinarily close vote of 60,853 to 60,095; and in Sept. 1917, in a referendum, woman suffrage was overwhelmingly defeated, 38,858 voting "No" and 20,604 voting "Yes." In 1924 the Ku Klux Klan was a very active factor in politics and one of the most discussed issues in the state campaign. The agitation, however, largely subsided following the election of Brewster as Governor in Sept. 1924.

Governors since 1911: Frederick W. Plaisted (Dem.), 1911; William T. Haines (Rep.), 1913; Oakley C. Curtis (Dem.), 1915; Carl E. Milliken (Rep.), 1917; Frederic H. Parkhurst (Rep.), 1921; Percival P. Baxter (acting) (Rep.), 1921–3, elected 1923–5; Ralph O. Brewster (Rep.), 1925– . (K. C. M. S.)

MAIRONIS, (1862–), Lithuanian poet, whose real name was Jonas Maciulas, was born in 1862 at Pasandvaris, in the Kaunas (Kovno) district. After leaving the Kaunas high school, Maironis continued his studies at the University of Kiev and the Kaunas seminary. On graduating from the latter, he entered the St. Petersburg (Leningrad) theological academy, where he took the M. A. degree. He was for 15 years a professor in the academy and received his D.D. for a scholarly work entitled *De Justitia et Jure*. In 1909 he was appointed rector of the Kaunas seminary. He became in 1922 a professor and deacon of the theological faculty of the Kaunas University which he helped to found, and in 1923 was appointed professor.

Maironis began to write at an early age. His prose, *History of Lithuania*, went into four editions. As a poet he excels alike in dramatic, epic and lyrical composition. His *Song of Spring*, a collection of songs, elegies, sonnets, ballads and satires also run into several editions. Many of his songs have been set to music and are sung all over Lithuania. His famous poem *Young Lithuania* describes the national re-birth; *Our Sufferings* is poem descriptive of the Lithuanian national ripening and conquest of independence; his *Magdalen of Raseiniai* castigates the national vices, while his Polish poem *Znad Biruty* appeals to the Polonised Lithuanian nobility. His dramatic works include *Where is Salvation? The Death of Kestutis*, and *Vytautas with the Crusaders*, the two last being historical plays of the 14th century. Maironis also translated the Rigveda into Lithuanian.

MALARIA (*see* 17.461).—Malaria had long been recognised as a disease of world-wide incidence and the cause of a higher ickness and death-rate than any other disease. The finding of malarial parasites in the blood cell by Laveran at Constantine in 880, the demonstration of the life cycles of the quartan and ertian species of parasite by Golgi in 1885, and of the subtertian ever species by Marchiafava and Celli, and the discovery that he disease is transmitted through the agency of mosquitoes first rom bird to bird by Ronald Ross in India 1897–9, and later rom man to man, in conjunction with the investigations and eachings of Patrick Manson and other pioneers, were important actors in a great stimulus to the study of tropical diseases, both of men and of animals in general, and the whole of tropical anitation was powerfully affected.

Parasites.—Malaria is due to small protozoa or animal paraites which pass an asexual stage in man, living and developing n the red blood cells, dividing into young forms or fresh broods n two or three days' time and producing some male and female orms (gametocytes), which are drawn with the blood into the stomach of the female mosquito, and there conjugate and complete a sexual cycle. An oöcyst forms from the female gamete and n this a swarm of young sporozoites develop and, becoming free n the body cavity, pass to the salivary glands, whence they are njected at the bite of the mosquito and begin again the asexual stage in man.

The Parasites.—Malaria parasites are of three species: *Plasmodium falciparum*, *P. vivax* and *P. malariae*, the causal organisms of "subtertian," tertian and quartan fevers respectively. Following the teaching of Laveran, a small body of workers believed that there was but one species, a theory of unity, and on the other hand certain investigators, because of minute differences between examples of the same species, concluded there were even further species and gave names to them. However, as Professor Marchoux pointed out in a thorough review of the question at the First International Malaria Congress held at Rome in Oct. 1924, experimental research generally tended to support the idea of plurality and existence of the three species above named. This was supported by the difference and practically constant periods of evolution of each, the transmission of the same species to healthy subjects, the specificity of culture of the parasites of each of the three species *in vitro*, and by epidemiological studies.

Symptomology.—In malaria symptomology nothing of fundamental importance has been discovered in recent years. There has been advance on our knowledge of the cause and treatment of Blackwater Fever or Haemoglobinuria, the serious nature of which has called forth many investigations, especially in the particular and heavily infected regions where it occurs. Some nvestigators hold that this condition may arise not only in nfections with *P. falciparum*, but occasionally with *P. vivax* and exceptionally with *P. malariae*. The association of an unknown virus with the malarial parasite has been considered as the cause. J. Thomson's work in Rhodesia in 1923–4 gave strong evidence in favour of *P. falciparum* as the causal organism of all local cases and possibly elsewhere. He showed that *P. falciparum* can almost always be found in the blood; and that cases had been living in a district heavily infected by *P. falciparum*. He found one case after five months and another after 40 years' residence; he noted its occurrence only in people who had had attacks of malaria, though possibly unrecognised as such at the time, and had taken their quinine inadequately in amount and over an insufficient period of time. A similar observation was made in the cases which developed Blackwater Fever on their way home, or after they had left an endemic area even for some time. The finding of the other species of parasite, both of which tend more to chronicity and are readily found in the blood stream, may when present be, in Thomson's view, but an indication of a mixed infection.

Diagnosis.—In the diagnosis of malaria in endemic localities the estimate of inhabitants infected is based on the percentage rate of an enlarged spleen or of a positive blood finding amongst a proportion of the population. For the latter, the examinations of a thick and a thin film of blood are made. In the absence of the parasite an estimate of the relative number of large mononuclear (endothelial) cells to other white cells in the blood may be made in certain cases, but the evidence obtained is not conclusive. An increase above the basic figure of 15% endothelial cells of the total white cells was taken by Stevens and Christopher as indicative of actual or recent malaria in Europeans living in the tropics. Blood cell counts made at some time prior and subsequent to the finding of the malarial parasite did not show the presence of a constant relative increase of endothelial cells, nor was this a constant factor in latent malaria, even when the clinical diagnosis was obvious and the most reliable factor, an enlarged spleen, present. With regard to the finding of the parasite in the blood in these cases of "latent malaria in England" it must be remembered that but a small drop is taken and that parasites are not easily found except at the period of a relapse. The clinical signs of latent malaria most commonly found are, in order of frequency, an enlarged spleen, anaemia, functional disorders of the heart and enlargement of the liver. The tendency to chronicity and febrile relapses in malarial infections is very marked.

Distribution.—Malaria is a world-wide disease with endemic foci in all countries. It is most prevalent and extremely common in the tropics with the native population and high infection rate, constant heat, moisture and water for the breeding of the anopheline mosquito and requisite temperature for the development of the sexual stage of the parasite therein. As the poles are approached, the foci of endemicity gradually become less. For the development of the parasite in the mosquito an adequate temperature is necessary. On an average the three forms, *P. malariae*, *P. vivax* and *P. falciparum*, take 14, 11 and 6 days, respectively, the time varying with the temperature. In subtropical countries, malarial outbreaks follow the rainy seasons, when opportunities arise for the breeding of the mosquitoes. Norway and Sweden are examples of countries wherein anopheles are present but malaria absent.

In Great Britain malaria was formerly not very uncommon, but became rare until the return of many infected troops. Related to the presence of these carriers there were 235 indigenous cases in England in 1917, the number falling to four in 1924, thus corresponding with the cure of the malarial carriers. There exist in England three species of *Anophelinae* in which the parasites may develop and be transmitted from man to man, but with treatment of infected cases from abroad there is now practically an absence of the human carrier of the parasites, or at least of parasites with sufficiently numerous sexual forms in the blood, a minimum of 12 per cu. mm. of blood being considered necessary for development in the mosquito. Climatic conditions, particularly temperature and humidity, influence the endemic prevalence of malaria. A mean daily temperature exceeding 60° F. is necessary for its propagation for the full development of the parasite in the mosquito, *P. falciparum* requiring a very high temperature; *P. malariae* completing its cycle at a low one, and *P. vivax* over a wide range of low to high. This explains the seasonal incidence of the three types of malaria, the relatively high incidence of *P. falciparum*, the most malignant parasite, and the large number of infected inhabitants and high death-rate in the tropics and subtropics, and its rarity in indigenous cases in temperate climes, the presence of the endemic foci of *P. malariae* in the cooler hill country in the tropics and subtropics and the universal distribution of *P. vivax*.

Though *P. falciparum* is the most malignant and spreads most rapidly when anophelism is intense, because of its greater output of gametes in the blood, it does not tend to such chronicity in the absence of reinfection as do the other two forms. In the absence of reinfection *P. malariae*, by far the rarest form, is, however, the most resistant and *P. vivax* holds an intermediate place. Of 28,270 blood examinations made in England at one laboratory on cases of malaria contracted during the War, 777 were found positive, and of these *P. vivax* numbered 759, *P. falciparum* 14, *P. malariae* 4. There was a marked falling off as the time in England lengthened, and it was rare to find the parasite after the quarterly period of 12 to 15 months. Seven cases were found after 30 months all with *P. vivax*, one in a double insection with *P. malariae* after 39 months, and one case after 51, and another after 59 months; *P. falciparum* was found after three months in a double infection with *P. vivax* at the 11th month, once alone at the 12th month, and once in a triple infection at the 14th month. The third of the four cases of *P. malariae* had also been home a long time, namely, 16 months. In none of this extensive series was the parasite ever found after five years at home. It is not uncommon to hear a person settled in a non-infective country for many years accusing a temporary febrile attack or period of lassitude as a return of malaria which he once contracted abroad. Proof of this seems wanting. Though malaria has been transferred directly from man to man, the parasites infecting man have not been made to infect any animal. Entomologists have furthered their investigations into the bionomics and classification of mosquitoes and the determination of the species of anopheles that carry malarial parasites.

S. P. James and Dale have recently reported that quinine, quinidine and cinchonine possessed the same curative properties for all forms of malaria, and without difference in their toxicity save for the greater cardiac depressant action of quinidine. Fletcher at Kuala Lumpur has made a careful series of observations on this point.

Prophylaxis and Treatment.—The treatment of malaria is intimately bound up with prophylaxis. Particular reference may, however, be made to the recent therapeutic use of horse serum in the treatment of that severe form of malaria, Blackwater Fever, wherein this serum appears to inhibit the action of an auto-haemolysin and its destruction of red blood cells in the body.

Many clinicians strongly advocate in tropical regions intramuscular and intravenous injections of the bihydrochloride of quinine in serious cases, and injections do act quickly in severe, malignant, remittent and comatose cases, but in ordinary cases oral administration of the sulphate has been satisfactory. In acute attacks it must be borne in mind that 24 hours or more may elapse before the good effects of quinine become manifest.

The classical successes in the reduction of malaria at Ismailia, Hongkong, Havana and elsewhere have encouraged similar work in other localities, but there are few such examples as the long continued labours of Malcolm Watson in the Federated Malay States and the brilliant sanitary victory of General Gorgas and the Americans over both malaria and yellow fever at Panama. The work of Darling, Bass and others in southern United States and in the Islands must also be mentioned. The method of mosquito reduction against malaria, first suggested and tried under Ross in Freetown, Sierra Leone, in 1899, has not been followed as widely as anticipated, and local authorities too often dislike spending money on sanitation and hamper practical efforts of sanitarians by the attitude that it is better to prevent malaria by quinine or by the use of mosquito-nets, measures which are impractical in an uneducated native community. Local conditions must always determine the most suitable mode of prophylaxis, and it is important, as Étienne Sergent points out, to have several methods of control which may well be combined and include with specific measures an educational propaganda. Obviously there must be action to eliminate infection from all carriers of the parasite: in other words, to prevent the mosquito becoming infected, to destroy the species of anopheles in which the parasite may develop, and to prevent their biting and inoculating the parasite into the blood of man. Good results have attended well-applied efforts of this kind. Better health results and there are real economic returns for expenditure. The native must be looked after and enjoined to adopt some sanitary methods until he is taught to share in systematised efforts to protect and cure himself of malaria as of other endemic diseases.

Measures to rid carriers of the parasite are most difficult to put into practice. There is no settled or fixed dosage, or time of administration, of the specific remedy, quinine or other of the cinchona bark extracts. Acute attacks respond readily to quinine; each dose makes a reduction in the number of parasites, and this reduction occurs every day, until finally none of the parasites is left. Treatment must be continued for a long time. Empirically three months appear to be enough, but there are obstinate cases.

Standard Treatment.—For some years a standard line of treatment to procure disinfestation has been adopted by Bass in America and by Ronald Ross and his colleagues in Great Britain and the former has been recently introduced by J. Thomson in Rhodesia. The two former vary slightly. Ross gives 30 grains of quinine daily during the attack and for three days after, followed by 10 grains daily, just before or after breakfast, for three months; Bass ceases after two months. Success has attended these standard treatments, and it is well for administrative purposes that a standard be adopted in each country. It will not cure all cases, but the exceptions appear rare and when detected can be specially treated. Stevens found arsenic, after initial doses of quinine, of great value in helping to eradicate the parasite. Together with quinine or other drug therapy, the important factor of building up and maintaining the general health, so as to assist the natural forces of the body to eliminate the malaria parasite, must not be forgotten.

Regarding the value of quinine prophylaxis amongst carriers the results obtained at the malaria centres and camps during the War showed that any dosage under a total of 60 grains weekly proved insufficient for an adult male. Other salts of quinine, of hydrochloride and bihydrochloride, affect the digestion less and seem to be as satisfactory. The tannate has been much used in Italy, especially for prophylaxis among children. The daily small dose is more easily and therefore more certainly taken by patients (out of hospital) than larger occasional doses which cause some dyspepsia and headache and are therefore frequently postponed. Children can be given a larger proportion by body weight than adults, say, twice as much. Sir Ronald Ross has always felt that, to be effective, quinine should be continued in 10 grain doses daily for three months after a subject has left a malarial country.

Quinine prophylaxis has been of value on particular occasions such as in tiding a body of troops over a critical period of fighting or passing through a heavily infected area, in that it has kept off attacks of malaria during that time. Bodies of troops in Salonika who were given quinine daily remained free as long as they were taking it, but went down with malaria as soon as they stopped it, showing they were infected in spite of it.

Not all people bear quinine continued over a long period well and they may show symptoms of quininism. Occasionally an individual is hypersensitive to quinine and may show symptoms even following an initial dose. On the first appearance of quininism the drug should be stopped for a time, or arsenical treatment substituted. In the hypersensitive case some begin with very small doses to desensitise the patient. Certain investigators in the tropics consider that it is more difficult to eliminate the parasite by quinine therapy in cases that have been taking quinine consistently and who have become infected in spite of it. The cost of quinine and of its supervised administration has frequently rendered quinine prophylaxis impracticable in certain endemic areas.

Quinine prophylaxis should be supported by measures to prevent mosquito bites as far as practicable. In endemic areas and where there are many carriers the infection rate of the mosquito may be very high and frequent reinfection may occur.

The second measure of prophylaxis, *i.e.*, the reduction of anopheline mosquitoes and the prevention of bites, has received more general application. This is difficult and costly, but it results in a lessened sickness and death-rate from malaria, and in profit from the expenditure incurred.

In subtropical regions or where mosquitoes hibernate in dark places in rooms of homes, cellars, stables, outhouses and such places, often attaching themselves to cobwebs, they should systematically be killed directly or by fumigation. The breeding place of the mosquitoes is any still water on which they lay their eggs, and to kill the larvae and pupal forms through which they pass in development is the object in view. Much can be done by the filling in of small pools, cattle foot-marks, draining of rshes, clearing out of long grass and reeds from the sides of eams, the conversion of still to running water when in large sses, the clearing away of all cans and unnecessary water tainers and the covering by gauze of cisterns and tanks and like around the homes. A female mosquito lays about 250 gs at one time and seven to 10 days bring them to maturity. e young aquatic forms may be destroyed by larvicides such kerosene, waste oil, cresol or "paris green," which, when mixed h 100 parts of dust (1 c.c. of the mixture to 10 sq. metres of ter) and blown on to the water, distributed by the winds or pped from aeroplanes, kills the anopheline larva forms and es not injure the fish or the animals that drink therefrom. uable agents against larvae and pupae are the surface-feed- minnows, gambusia, stickleback and perch.

Anopheline mosquitoes do not attack until sunset, when one y remain as far as possible indoors in houses, bungalows and ts protected by close-mesh wire or netted windows and double ors; a bed or head net should cover any exposed part of the dy during sleep. In the early evening the wearing of puttees men and a paper lining under the stockings of women prents bites on the legs. Coolie lines should be placed when ssible a mile from the breeding places of the anopheles, ough this does not mean that the mosquitoes cannot fly much rther. There is little danger to be anticipated from breeding aces over a mile distant, if the mosquitoes have opportunities feeding close at hand (*i.e.*, from other mammals), and if the tervening space be raised, wind-swept and clear of all shrubs d trees. The knowledge that the mosquito will attack man or imal in its thirst for blood has raised certain questions regardg the preservation of game, but up to the present no practical udies on any extensive scale have been made.

Use in Psychiatry.—Following the observation of Wagner uregg in Vienna in 1917, that certain chronic conditions showed provement after malarial attacks, the therapeutic use of alaria in psychiatry has been extensively applied in many untries. Many cases of general paralysis have benefited, some fficiently to be able to return to family and social life. Time ust be given to determine the permanency or otherwise of the melioration. Its use in other cases of cerebrospinal syphilis d also in such mental diseases as *dementia praecox*, confusional sanity and *encephalitis lethargica* is under consideration. The arasite used is the *P. vivax* and it appears more satisfactory to oculate the patient by an experimentally infected mosquito an by infection with blood from a case of malaria. Thereby risks of other infection are avoided, a wise precaution, espeally in an endemic region where other species of the parasite cur. Infected cases are allowed to have 6 to 10 febrile attacks malaria and are then given quinine which in these experimenl cases readily cures the attacks.

War Malaria.—The following were the British War Office figures the number of cases admitted to hospital in four of the fighting reas during the War: Mesopotamia: 1916, 680; 1917, 744; 1918, ,202. Salonika: 1916, 31,059; 1917, 71,413; 1918, 59,087. East frica: 1917, 58,236; 1918, 20,015. Egypt: 1916, 1,423; 1917, 8,480; 918, 30,241.

Until the War spread to the eastern fronts British armies suffered ttle from tropical diseases. In the summer of 1916 an epidemic of alaria occurred among the troops on the Salonika front; and coninued until the end of the War.

Following the outbreak of malaria at Salonika, Sir Alfred Keogh, he Director-General, Army Medical Services, early in 1917 appointed special malaria hospital in each Command in the United Kingom, for the express purpose of finding a permanent cure if possible, nd of treating the thousands of men who were being returned home ick with malaria from the eastern fronts, Sir Ronald Ross being also ppointed Consultant in Malaria at the War Office. The fact that oderate doses of quinine will control actual attacks within a few ays was fully verified, and with very few exceptions. Almost every orm of treatment that had ever been suggested—enormous doses of uinine reaching 100 grains *per diem;* smaller doses continued for hree weeks or more; additional medication with arsenic and other rugs; continuous doses lasting for a month, and various kinds of nterrupted dosage—all proved uncertain. Thirty grains of quinine, ontinued every day for three weeks, proved a failure. Intramusular injections and even intravenous injections did no better. Men vho were presumed to be cured relapsed again after returning to uty; a large proportion of those infected with malaria became almost useless for further service. Numerous nostrums advocated for malaria proved valueless, the only exceptions being one or two arsenical preparations, which, however, were *no better* than ordinary quinine.

Now, in all these attempts, treatment had seldom been continued for more than one month and rarely or never for more than two months—owing, of course, to military exigencies. It was decided to deal with the large numbers of discharged soldiers by a longer period of treatment. In 1918 two whole divisions, full of malaria, had been brought from Salonika to France and were there subjected to a longer course of treatment preparatory to their being sent again into the firing-line. The regiments arrived in an extremely bad condition, were all placed in camps in the Dieppe region, and the men were given 15 grains of quinine in solution once daily for a fortnight, followed by 10 grains of quinine in solution daily for 2½ months more. The course, designed and carried out by Col. J. Dalrymple, had marvellous results, almost the whole of the two divisions being found fit for the front at the end of the three months. About the same time large malaria concentration-camps were established in England, where cases were given similar treatment, but for shorter periods; and it was found generally that: (1) doses of less than 10 grains daily did not suffice to prevent relapses even while they were being taken; (2) doses of 10 grains daily did so suffice, except in about 6% of the cases, most of whom, however, relapsed during the first days of the treatment; (3) 15 grains a day reduced the relapses still further, but only to about 4 or 5%.

The long-continued treatment of malaria was now proved to be satisfactory, and was extended to pensioners also. In one London clinic alone nearly 30,000 pensioners have been treated in this way. The results have been admirable, and probably very few men who have taken the treatment properly have returned. But the 10 grains of quinine must be taken religiously every day, and it is well to associate this with or follow it by a course of arsenic. Quinidine replaced the quinine in a small number of these cases. Good food and care in building up the general health are important factors in overcoming malarial infections. Empirically, three months appear to be enough, but in obstinate cases four months might be better. There are rare individuals who are hypersensitive to quinine or who may be desensitised prior to the introduction of the standard dosage. Even long courses of treatment will not necessarily cure people who are subject to reinfection during treatment; and it is even possible that they are not so effective during the first six months or the first year of infection as they are later. The results described above were obtained among returned cases in Britain. Other salts of quinine besides the sulphate were tried. The hydrochloride and bihydrochloride affect the digestion less and seemed to be as satisfactory.

The prevention of malaria on the battle-front was always difficult and sometimes impossible. Mosquito-reduction in the face of enemy fire is impracticable; quinine prophylaxis was under such conditions disappointing; and the armies were obliged to fall back upon mosquito-nets and mosquito-proof tents and bivouac shelters—which were carefully designed by the British War Office. Better results were obtained at the bases of operations, especially in Palestine; and a very successful campaign of mosquito-reduction was carried out by Col. J. C. Robertson at Taranto in Southern Italy.

Lemaire, *Malaria in Macedonia*, ed. by Sir Ronald Ross (1918); War Office, *Observations of Malaria by Medical Officers of the Army*, H.M.S.O. (1919); M. Watson and others, *The Prevention of Malaria in the Federated Malay States* (1921); Sir R. Ross, *Memoirs: With a Full Account of the Great Malaria Problem and Its Solution* (1923).

(R. Ro.; W. B.-A.)

MALAY STATES, FEDERATED (*see* 17.478).—For over 16 years all matters of common interest to the Federation have been settled by the federal council, a body created in 1909 in accordance with the general wishes of the individual rulers. The council consists of the high commissioner (president), the chief secretary to the Government, the four ruling Sultans, the four British Residents, the legal and financial advisers and eight nominated unofficial members; it meets generally three times a year and all Federal legislation is passed by it.

Population.—The growth of the population is the measure of the States' prosperity. According to the census of 1921, the population was 1,324,890, having increased since 1911 by 27·7%; it is still rising rapidly, and was estimated at the end of June 1924 to be 1,418,455. There are approximately 510,000 Malays, 494,000 Chinese, 305,000 Indians and 5,700 Europeans. The increase among Malays, especially in Selangor, is largely due to the influx of foreign Malays who have settled in the coast districts to plant rubber; and the increase in the Indian population also synchronises with the development of the rubber industry. There are indications that the immigrant races, who have done so much to develop the resources of the Federated Malay States, are ceasing to regard these States as a place of temporary sojourn and tend more and more to make them their permanent home.

Commerce and Industry.—An indication of the continued prosperity of the States is afforded by the fact that for the six years following the World War there was a considerable trade balance; and for the years 1919, 1923 and 1924, the estimated value of the exports, which consist chiefly of tin, rubber and copra, was well over twice that of the imports. The average value of the exports is over 200,000,000 dollars. The export of tin-ore reduced to a metallic basis and of block tin has averaged 40,000 tons, and the market for this commodity, as also for rubber, has been greatly assisted by the policy of withholding stocks against current prices. In the case of tin the holding or releasing of stocks was arranged by voluntary agreement between the Government, which held large stocks, and private holders.

Government assistance to rubber growers was given by the Export of Rubber (Restriction) Enactment, under which the percentage of release of stocks at the minimum duty rose or fell according to the ruling market price. By this means a fair price was obtained for growers, and many plantations were saved from the ruin that must have resulted from the premature tapping of trees. The Government continues to make a grant to the Rubber Growers' Association in connection with propaganda for new uses and markets for rubber. The establishment of a rubber research institute was approved in 1924, to be maintained by a special export duty on rubber. Important research work had been done, before this, on the deterioration of rubber in storage, which was found to be due mainly to surface oxidation, from which it is indicated that the slab form is preferable to the crêped form for storage. The mouldy rot disease (in Negri Sembilan) and the brown bast disease were further investigated. A Government experimental coconut plantation has been started. The commercial timbers of the country are in process of being scientifically investigated, and the distillation of native woods has also been made a subject of research.

Tin-mining continues to be the chief industry in Perak and Selangor and rubber the chief industry in Negri Sembilan and Pahang. Other ores produced are tungsten (wolfram and scheelite) and gold. The Raub gold mine in Pahang is the only gold mine now working in these States; but alluvial gold is recovered in various places. Coal also is produced, the tonnage averaging between 350,000 and 400,000 tons annually. Coconuts and rice are widely grown in Perak, Selangor and Negri Sembilan, in which last-mentioned state coffee is now but little grown, its place being taken by rubber. The timber industry is in process of development, and the whole question of the exploitation and conversion of timber is receiving the active consideration of the Government. Already there are some 5,000 sq. m. of forest reserves, and the areas are being extended.

Railways.—Communications in the Federated Malay States keep pace with the growing requirements of the tin and rubber industries. The total length of line now open to traffic under the Federated Malay States railway administration is over 1,000 miles. This includes the Johore state railway, which at Gemas branches into the west coast line to Prai and to the Siamese frontier; and the east coast line, which runs northward towards Tumpat. The Kelantan section is being extended southward to the east coast line to provide direct communication between Kelantan and Singapore. Through traffic, over the west coast line, with the Siamese state railways was opened in 1918, and between the Federated Malay States and Kelantan via the Siamese railway in 1921. The Johore causeway, which connects Singapore with the peninsula, was opened in 1924. The causeway carries two lines of rails and a roadway; its total length is 3,465 ft. and its average headway at low tide is 47 feet.

Education.—In 1919 important movements for the extension of education were set on foot, despite difficulties encountered in increasing the number of teachers and the improvement of the teaching standard. A temporary scholarship scheme for sending teachers to Hongkong University was set on foot, to serve until more training colleges were established and pending the opening of Raffles College, founded in Singapore. A Malay college is established at Kuala Kangsan; the Sultan Idris training college provide Malay vernacular teachers; and there are many Chines and Tamil vernacular schools.

MALAY STATES, NON-FEDERATED (*see* 17.482).—These are Johore (*see* 15.475; this form of the name, rather than Johor has come into official and general use), Kelantan, Trengganu Kedah and Perlis. The populations according to the census of 1921 were Johore, 282,234; Kelantan, 309,300; Trengganu, 153,765; Kedah, 338,558; Perlis, 40,087.

Malaria is severe except in Trengganu, and infant mortality high, but both this and the general death-rate have been reduced with improvements in sanitation and provisions for medical service introduced under British supervision. To this, and to the more settled conditions brought about under it, is attributed in large part the substantial increase of the population recorded in all the States; although, as in Trengganu about 1920, the benefits to the commercial classes were not immediately reflected in improved conditions for the peasantry.

By an agreement made in 1885, the Sultan of Johore placed his foreign affairs under British Govt. control and undertook, when required, to receive a British agent at his court. No such appointment, however, was made until 1910. In 1914 a subsidiary agreement was concluded whereby a General Adviser was appointed with powers similar to those exercised by British Residents in the Federated Malay States. The other States, Kelantan, Trengganu and Kedah, came under British protection in 1909 by virtue of a treaty signed at Bangkok in 1909 under which the Siamese Govt. transferred to the British Govt. all its rights over them. The officer administering the government of the Straits Settlements is the British High Commissioner for all protected States in the Malay Peninsula.

Johore.—Most of the interior of Johore is covered with jungle, but already over 800,000 ac. have been alienated, chiefly in small holdings, for cultivation. Rubber plantations occupy half this area and coconut crops about 90,000 acres. Other agricultura products are padi, betel nuts, African oil palms, tapioca, sago palm, gambia, pineapples, tuba and patchouli. The chief minera resources are tin-ore and iron-ore. China-clay is worked, but owing to impurities, has not been found suitable for use in the Bombay cotton-mills. Good forest country exists north of Labis, and timber production averages 20,000 tons a year. The export trade is of the average annual value of $50,000,000, of which rubber represents three-fifths, copra, tin-ore, preserved pineapples, areca nuts and gambia, the greater part of the remainder. The Johore State Railway from Kuala Gemas to Johore Bahru is now leased to the Federated Malay States. The total length of roads maintained by the Government is over 600 miles.

Kelantan.—The dominating physical feature of Kelantan is the flat plain of 1,000 sq. m., extending behind the low sandy coastline. This plain is densely populated, and closely cultivated with rice, coconut and fruit trees. Of the total population in 1921 286,363 were Malays, for the most part born in Kelantan. Chinese numbered about 12,000. The broken hilly country south of the plain is thinly populated, but it contains the bulk of the foreign-owned estates. The staple produce is rice, most of which is grown for domestic consumption. Rubber, coconuts and betel nuts come next in importance. Other notable industries are fishing and weaving; but there is no mining worth mention, though tin mining is likely to develop with increased transport facilities. Recent prospecting indicates the possibility of gold being found in payable quantities. The total volume of trade is valued at about $9,000,000, of which exports represent about $5,500,000. The chief exports are gums and resins (mainly Para ubber), copra, dried betel nuts, dry and salted fish, poultry and attle, silk and cotton goods and dried hides.

Trengganu.—With the transfer to Great Britain of the Siamese uzerainty over the State of Trengganu in 1909, the sending of he triennial tribute of Bunga Mas (gold and silver filigree flowers) o the King of Siam ceased, and a British Agent with consular owers was appointed. In 1919, following the report of a commission of inquiry, the agent was replaced by a British Adviser, whose advice must be sought and followed in all matters of general administration and all questions other than those touching the Mahommedan religion. The soil and climate are suitable for the cultivation of Para rubber, coconuts, coffee and pepper; but the otentialities of the country lie in its mineral resources. Trengganu is the least opened up of the Unfederated States; but it is undoubtedly rich in minerals: tin (lode and alluvial) and wolfram are worked, and graphite, hematite, magnetite and monazite have been found. The total value of the trade of the State is about $9,000,000, of which exports represent nearly $5,500,000. The bulk of these, consisting of Para rubber, dried fish, tin-ore, and copra, go to Singapore. Agriculture employs over 48,000 people and fishing 9,000. About 95% of the population are Malays. Many of the Malay inhabitants show special commercial aptitude, and it is noteworthy that there are here intances, rare elsewhere, of Chinese trade financed by Malay apital.

The suzerainty of Kedah also passed to Great Britain in 1909 and the administration of the country was finally adjusted by a treaty signed at Singapore in 1923. The population in 1921 was 38,544, of whom 237,043 were Malays, 59,403 Chinese and 3,019 Indians. Only about 100 of the aborigines (Sakeis) are eft, these being mostly located in the forest region of the Muda iver. In North Kedah the people are mainly employed in ultivating rice, and in South Kedah, rubber, coconuts and apioca. The estimated annual value of the exports is about 21,000,000, over 50% of which represents rubber. There are everal good metalled roads communicating with Province Wellesley, Singgor and North Perak. The Federated Malay States railway administration has extended its service through Kedah into the independent and protected State of Perlis and rains have been running regularly since 1915. Bangkok and Singapore are now linked up by a connection through Perlis.

Perlis.—The principal industries in the small State of Perlis are rice cultivation and tin-mining. Most of the exports go to Penang, with which country there is regular and frequent steamer ommunication.

Survey and Land Settlement.—One of the principal reforms undertaken under British advice has been that in land settlement, the demarcation of property boundaries, and the issue of itles. To this end trigonometrical surveys have been underaken. In Johore by 1925 a Settlement Act was in force in the districts of Muar and Batu, but not in other districts owing to he want of surveyors. In Kedah the survey is expected to be inished in 1927, and the Survey Department of that State has also supervised the work in Perlis. In Trengganu a settlement enactment was passed in 1924. Education has also received lose attention. The new system in Johore, in which English s taught concurrently with Malay, promises success. The chief English school is that of Bukit Zohara at Johore Bahru. Educaion has also notably advanced in Kedah, where there are government English schools at Alor Star and Sungei Patani.

A notable inscription in Malay on a stone pillar, of date 1303, was discovered in 1923 near Kuala Trengganu. It has a strong admixture of Sanskrit and some of Arabic, and deals with certain phases of Islamic law. No example of this association of languages of earlier date than 1468 was previously known, and this inscription, which has been deposited in the Raffles Museum at Singapore, forms by far the earliest known record of the penetration of Mahommedanism into the Malay Peninsula.

MALINES, Belgium (*see* 17.489), had a population of 60,429 in 1923. The town was bombarded three times during the World War, and much damage done. The old Palais de Justice, restored shortly before the War, the school of music and the picturesque houses round the Bailles de Fer were ruined, and the south side of the cathedral and the chimes badly damaged. The cathedral was in progress of restoration in 1926. The Cloth Hall, also restored before the War, is used as the town hall. In 1924 the conversations between the Archbishop of Malines, Cardinal Mercier, with some dignitaries of the Anglican Church about the cause of Christian Reunion brought Malines again into public notice.

MALLOCK, WILLIAM HURRELL (1849–1923), British author (*see* 17.492), died at Wincanton, Somerset, April 2 1923.

MALMÉDY: *see* EUPEN AND MALMÉDY.

MALTA (*see* 17.507).—The period 1910–25 comprises changes of paramount importance in Malta, of which the most important are consequent on the World War of 1914–8. The Maltese provided a garrison for Malta, many seamen and stokers for men-of-war and minesweepers, and labour battalions for Gallipoli and Salonika; and they did excellent service in the hospitals. These services contributed to the grant of responsible government, which was established by the constitution of 1921.

Constitution.—On June 12 1920 the governor, Lord Plumer, communicated the decision of the British Govt. to grant a form of self-government which provided for responsible control by the Maltese ministers of local affairs. The letters patent came into force on May 16 1921, and provided for the creation of a senate of 17 members, with a legislative assembly of 32, the latter elected by proportional representation and having control of its own ministers. Judges are to be appointed by the governor in council, and can only be removed by a joint address from both Houses of the Legislature. The police are under ministerial control. Each House makes its own standing orders and rules, and defines its privileges; such powers, however, are not to exceed those of the British House of Commons. Debates may be conducted in English, Italian or Maltese; but all official entries are to be in English or Italian. All persons are to enjoy full religious liberty, no person is to be subjected to any disability or exclusion from office on the grounds of religion. A covering despatch empowered the legislature at its first sitting to declare Roman Catholicism the state religion. English is declared the official language of the administration: Italian is to be the official language of record in the law courts. British subjects, not of Maltese birth, may claim to be tried in the English language.

By the new Letters Patent, power to make laws regarding reserved matters—including everything pertaining to defence, the control of foreign relations, coinage and external trade—remains in the hands of the governor and commander-in-chief, assisted by a nominated council consisting of the lieutenant governor and the legal adviser (as ex-officio members) with senior officers of the navy, army and air force.

Population and Emigration.—The civil population, including Gozo and Comino was estimated on Dec. 31 1924 at 223,088; according to the census of 1911 it was 219,311. The death-rate in 1924 was 23.22 per 1,000 as against an average of 22·57 during 1910. Economic conditions became critical after the cessation of the War. The number of unemployed was swollen in 1919 by the discharge of about 15,000 men by the naval and military establishments, whereupon organised emigration was necessarily resorted to in order to ensure a suitable outlet for Maltese labour. The number of emigrants in 1924 reached the total of 3,277. The distress prevailing among the poorer classes after the War caused the Government to continue the bread subsidy in 1920 and a grant in aid thereof amounting to £250,000 was made from Imperial funds. General want and discontent led to serious disorders and to loss of life by riots on June 7 1919.

Schools.—On Dec. 31 1924 the number of Government day schools was 597. There were 58 private schools with a total of 26,744 scholars. The estimated expenditure on all branches of education for the year 1925 to April 1 was £92,370, excluding buildings. The teaching of Italian in the infant schools and in the first and second year of the elementary schools was entirely abolished in 1923.

Finance and Trade.—The revenue for the year ending April 1 1925 was £773,015 and the expenditure was £757,966; as against, in 1910, revenue £436,200 and expenditure £458,012. The amount of British treasury currency notes in circulation on March 31 1925 has been estimated at £750,000.

The total number of acres under crops in 1924 was returned at 42,964. It is estimated that the agricultural produce of the islands could only support the present population for three months in the year; the balance of foodstuffs and necessaries has to be paid for by work done for the Imperial forces, for the dockyard and for visitors and tourists, and also by large remittances to relatives at home which are received from Maltese abroad; moreover interest from investments outside the islands, and accumulated capital furnish margins to adjust the adverse balance.

Trade (inclusive of goods by parcel post but exclusive of bullion and goods in transit) was as follows:—

	1914	1924
Imports	£2,510,934	£4,416,453
Exports	1,053,854	1,451,766

The exports in 1924 include £443,798 value of coal furnished to merchant ships. In 1924 the value of imports from the United Kingdom was £1,367,291. The number of British steamers calling (not including war vessels and transports) was 349, with the aggregate tonnage of 989,517, and of foreign vessels 411, tonnage 696,501.

Defence.—The increased importance of Malta as a naval base was developed considerably in 1925, producing a period of increased prosperity; a floating dock was installed in 1925 capable of lifting the largest ships. An aerodrome has been built at Hal Far, suitable for main line airways. The greater part of the fortifications has been made over for civil purposes, in view that the importance of aircraft has altered fundamentally the needs and methods of military defence.

Antiquities.—Palaeological investigations have been continuous and excavations at the cave of Ghar Dallam have yielded important results among which were the discovery of human teeth assigned to the Neanderthal period and remains of many species of animals. In the period of 1910–25 archaeology has been enriched by further excavations of neolithic temples, and by the announcement of Professor Keith that the collection of bones at Ghar Dallam are due to that locality having been adapted by the prehistoric inhabitants as a pitfall to catch elephants and other wild animals when Malta was part of an isthmus which connected Italy with Africa, and was in the neighbourhood of a fresh-water lake.

See M. H. Egan, *Notes on Malta* (1922); P. F. Bellanti, *Studies in Maltese History* (1924). (G. St.*)

MALVY, LOUIS JEAN (1875–), French politician, was born at Figeac Dec. 1 1875. In 1906 he entered the Chamber as a Socialist-Radical and was an under-secretary in the Monis and Caillaux cabinets (1911), Minister of Commerce and Postal Services under M. Doumergue (Dec. 1913) and minister of the interior in the Viviani Ministry (June 1914). He retained this post under M. Briand and M. Ribot. On July 22 1917 M. Clemenceau charged him with lax administration in dealing with defeatists and agitators, and he resigned on Aug. 31. In October M. Léon Daudet brought against him a general accusation of treason. A commission, appointed at M. Malvy's own suggestion, decided on behalf of the Chamber that the Senate, sitting as a high court, should pronounce judgment on all the stated charges. On Aug. 6 1918 the high court acquitted M. Malvy of the charge of treason, but found him guilty of culpable negligence in the performance of his duties as Minister of the Interior from 1914–7, and sentenced him to banishment for five years, which he passed in Spain. In 1924 he represented France at the Morocco negotiations which took place in Spain, and in Oct. of the same year became president of the finance commission of the Chamber. M. Malvy again became Minister of the Interior in the Cabinet formed by M. Briand in March 1926, but he resigned in the following April. (*See* FRANCE.)

MAN, EVOLUTION OF.—The late Sir E. B. Tylor, writing on the evolutionary theory of man's origin, made the following statement: "In one form or another such a theory of human descent has, in our time, become part of an accepted framework of zoology, if not as a demonstrable truth, at any rate as a working hypothesis which has no effective rival." When Sir Edward Tylor made this statement in 1910 he was in his 78th year; his memory could carry him back to a time when it was believed that man had come into the world as a special creation some 4,000 years before the birth of Christ and owed no kinship to other living things. He was 27 years of age when Darwin's *Origin of Species* was published in 1859; in 1865, two years after Huxley had issued his renowned treatise on *Man's Place in Nature*, he himself published a work which threw a new light on human history, *Researches into the Early History of Mankind and the Development of Civilization.* When Darwin's *Descent of Man* came out in 1871, Tylor's *Primitive Culture; Researches into the Development of Mythology, Philosophy, Religion, Art and Custom*, kept it company. By the end of the 19th century he had seen chair after chair in the universities of the world filled by men who were convinced that evolution was true; at his death in 1917, at the age of 85, he had seen another generation of inquirers grow up who, after applying Darwin's teaching to all departments of man's world—to his body, mind and culture—remained convinced that, as a working hypothesis, the doctrine of evolution had no rival.

SUMMARY OF THE EVIDENCE

Embryology.—No matter what aspect of man the student of to-day may select for study, the conviction that evolution (*q.v.*) is true is forced on him. If he investigates the development of the child in the womb he comes across a complicated series of appearances which can be explained only if Darwin's teaching is accepted.

Comparative Anatomy.—If he studies the structure of man's body he finds it framed on the mammalian plan, and if he compares it with that of anthropoid apes he finds the points of resemblance to be so numerous and so close that he cannot think that such a degree of resemblance could be a result of mere chance. If he inquires into the periods through which a newly born child passes to reach manhood or womanhood, he finds the animals which are most human in this respect are the great anthropoids—the gorilla, chimpanzee and orang. If he takes into consideration the diseases to which man is liable, he finds that human diseases are more readily communicated to the great anthropoids than to any other living animals. Particularly is he impressed by the fact that the blood of man and of the anthropoid apes, when tested against each other, react almost in the same way. To account for the presence of so many vestigial structures in man's anatomy, he feels impelled to suppose that man has come of an ancestry in which these vestiges were fully grown and useful. A child may be born with its body malformed; it may suffer from hare-lip, cleft-palate or many other kinds of deformity, including the presence of a tail; medical men cannot account for such malformations if they look on man as a special creation; they can give a rational explanation of their occurrence in man's body if they accept the teachings of evolution.

Palaeontology.—In recently formed strata of the earth fossil forms of man are found; those from the older strata are more ape-like than those from the newer. In still older strata are found fossil fragments of great anthropoids; in still more ancient, the remains of small anthropoids; deeper still in the earth's records no trace of anthropoid has yet been discovered. In these older strata occur fossil remains of small monkey-like primates. The geological records, so far as they are yet known, support Darwin's theory of man's origin; they are altogether against the belief that man appeared suddenly—a special act of creation.

Human Races.—More especially is the student of human races driven to Darwinism for an explanation of his many problems; even if he believed that man had appeared originally by an act of special creation he must formulate a theory of evolution in order to account for the divergent races now living.

Although in thought and deed man rises far above any member of the brute creation, yet students of his brain find that it is modelled, part for part, on exactly the same pattern as that of he anthropoid ape. Those who inquire into man's mental qualities, his emotions, his habits, his tendencies and his modes of thought, find much which can be explained only by supposing hat he has ascended from a lower order.

For these reasons all present-day students who are applying hemselves seriously to the unravelling of man's history accept he theory of evolution as a truth. This conviction has spread rom professional circles into the public thought of our time and altered the outlook of a large section of the lay mind; yet here still remain numbers of the public of Europe and of America who, impressed by the great and real differences which separate the mentality of the lowest grades of mankind from hat of the highest grade of ape, cannot believe that man has arisen from a lower form by any natural or evolutionary process. The State of Tennessee has passed a law forbidding, in state-supported schools, "the teaching that man has descended from a lower order of animals." In June 1925 Mr. Scopes, a school teacher, was prosecuted under this law, found guilty and fined $100. Since then certain other states have enacted similar laws.

Man's Genealogy

Darwin's Views.—Although there is a complete agreement among professional students that man is a member of that order of mammals to which Linnaeus gave the name "Primates" and that his lineage, when traced backwards, will be found to branch off from the primate tree, there is a sharp difference of opinion as to the exact point in the tree, and the approximate date in geological time, at which the human branch separates from those other main branches which represent the lineage of anthropoid apes and of monkeys. It is clear from statements made in the *Descent of Man*, that Darwin regarded the gorilla and chimpanzee as more nearly akin to man than other living primates and, on the evidence available in 1871, thought it probable that man and the African anthropoids were co-descendants of a common anthropoid which had its habitat in Africa (fig. 1). He regarded the catarhine type of monkey—the type exemplified by the monkeys of the Old World—as representatives of a still older ancestral form. Darwin traced the common anthropoid stock, which gave birth not only to the ancestral lines of man, the gorilla and chimpanzee, but also to those of the orang and gibbon, back to a common catarhine type. This catarhine type, he presumed, was the offspring of a still older common simian or monkey-like type, one which existed in the Eocene period of the earth's history and gave origin not only to the catarhine monkeys of the Old World but also to the platyrhine monkeys of the New World. Thus man's history, as Darwin saw it, did not begin until after the ancestral type of anthropoid had been evolved; the appearance of an anthropoid type from a common catarhine ancestor and this from a common simian stock, represent prehuman stages in the evolution of the higher primates. It is noteworthy that Darwin's mind remained open as to the exact point at which the human stock branched off from the general primate tree; more than once in the *Descent of Man* he writes as if the human lineage might have come off, not from the anthropoid stem, but lower down in the primate tree, from that of the common catarhine stock (fig. 1a).

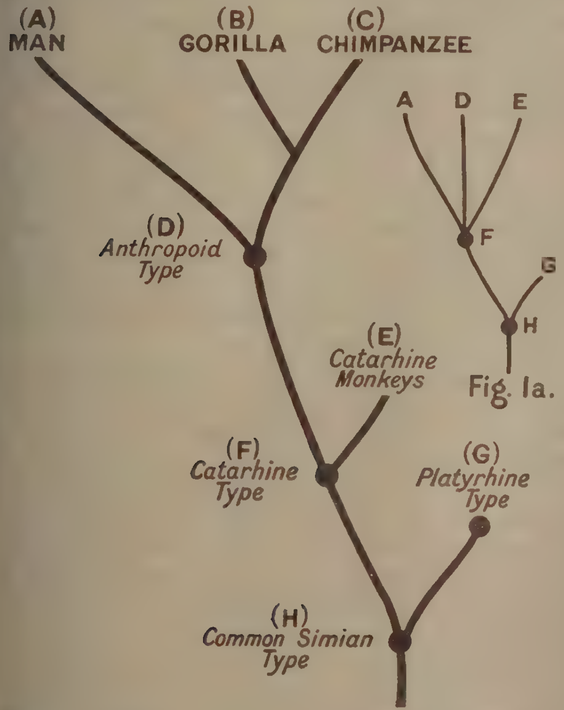

FIG. 1.—A diagram to illustrate Darwin's conception of Man's lineage.
FIG. 1a.—Another possible relationship, also mentioned by Darwin.

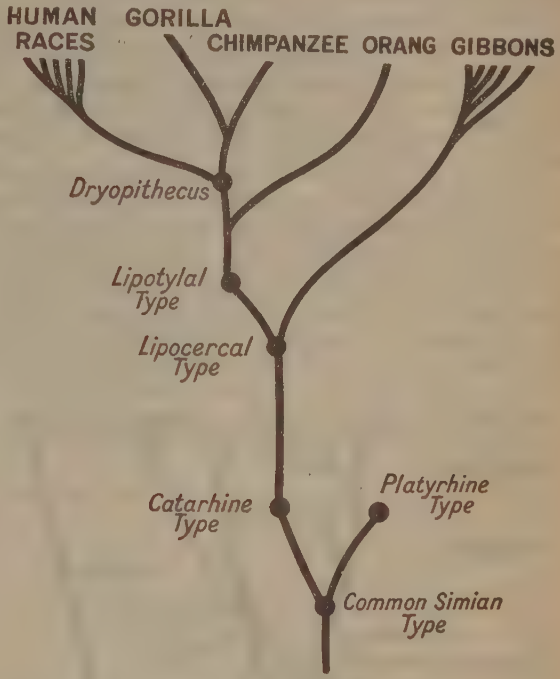

FIG. 2.—Haeckel's conception of Man's descent as illustrated by a phylogenetic tree, published in 1866.

Haeckel's Views.—On no occasion did Darwin throw his conception of man's lineage into a diagrammatic form. The first to construct an evolutionary tree of man's descent was Ernst Haeckel; this appeared in his *Generelle Morphologie* published in 1866, five years before Darwin's *Descent of Man* was issued. This pedigree is still worthy of study (fig. 2). Haeckel perceived that the small form of anthropoid ape, the gibbon, was more primitive and earlier in point of evolution than the three living great anthropoid apes (orang, chimpanzee and gorilla) and supposed that in the evolution of the great anthropoids from the ancestral catarhine type there was interposed a small anthropoid stage to which he gave the name Lipocerca (λιπεῖν, to lack, κέρκος, tail). This small anthropoid stock (Lipocerca) gave origin, he supposed, to gibbons and to the ancestral stock of the great anthropoids—for which Haeckel proposed the name Lipotyla (λιπεῖν, to lack, τύλη, cushion)—anthropoids which, unlike the gibbons, were destitute of ischial callosities or natural cushions on which gibbons and Old World monkeys seat themselves. This cushionless anthropoid stock (Lipotyla) he regarded as ancestral to the various races of mankind. From the Lipotyla, which gave origin to man, there also branched off, at an early stage, the ancestry of the orang and, at a later, the common ancestry of the chimpanzee and gorilla. Thus Haeckel regarded the gorilla and chimpanzee as more nearly related to man than other living anthropoids. It is also remarkable that he placed the extinct Miocene form of anthropoid ape, known as Dryopithecus, on the line which led up to the gorilla and chimpanzee on the one hand and to human races on the other. Thus it will be seen that in Haeckel's opinion man was the descendant of an anthropoid ape.

Later, he introduced considerable modifications into this family tree. In the third edition of his *Evolution of Man* (English translation, 1879) he interpolated into man's ascent from an anthropoid to a human state an intermediate stage represented by *ape-like* men—beings who were manlike in form and in gait but lacked man's power of speech. To such hypothetical beings he gave the name *Pithecanthropi.*

Modern Views.—In 1892 Prof. E. Dubois discovered in the island of Java the fossil remains of a being which answered very well to this hypothetical stage, and named this fossil form of evolving man *Pithecanthropus erectus.* Haeckel presumed that his pithecanthropi had lived in the Pliocene period; Prof. Dubois is of opinion that his transitional form of man lived in Java towards the end of the Pliocene period. Discoveries made by Dr. G. E. Pilgrim of the Geological Survey of India and by members of that survey in the latter part of the 19th century have proved that India, during the Miocene period and the earlier part of the Pliocene, was the home of great anthropoids of many and diverse kinds, several of them belonging to the type of Dryopithecus which Haeckel, at an early period, regarded as a possible ancestor to man. Others of these fossil Indian or Siwalik anthropoids show affinities to the orang, to the chimpanzee and to the gorilla, while still another—*Sivapithecus*—is regarded by Dr. Pilgrim as an early representative of the human family. Notwithstanding these revelations from India and taking all their bearings into consideration the majority of modern authorities (Dubois, W. K. Gregory, Elliot Smith, Keith), in constructing diagrams to illustrate the affinities and lines of descent for the higher primates, depict the human stem (fig. 3) as springing from the vicinity of the stem which gave rise to the gorilla and chimpanzee. The conception, first formulated by Haeckel, that a Miocene anthropoid of the type of Dryopithecus (fig. 3) may stand as a common ancestor to man and to the African anthropoids is still regarded as possible.

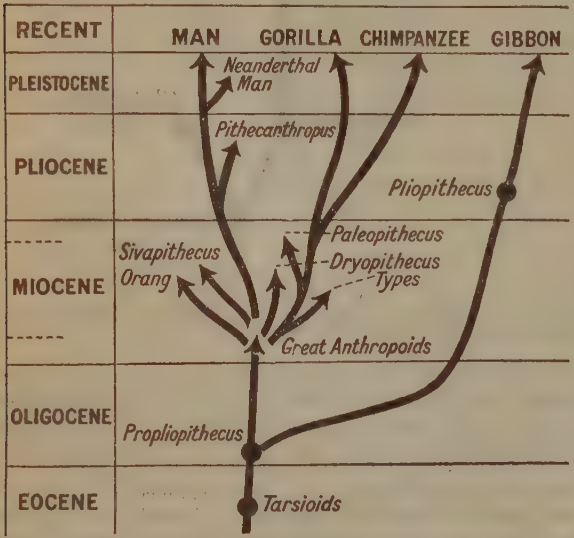

FIG. 3.—A phylogenetic tree of the higher primates (after W. K. Gregory, 1916).

Doubts Raised by the Occurrence of Parallel Evolution.—There is a line of evidence, accumulating at the present moment, which tends to undermine the confidence of those who have drawn up phylogenetic trees of man's descent. All who have inquired into the evolution of horses and elephants, by the study of fossil forms found in widely separated regions of the world, have become impressed by the fact that horses and elephants in America have passed through evolutionary changes of the same kind and in the same order as have done their representatives in the Old World. This tendency for the descendants of a common ancestry to undergo *parallel* or even *converging* evolution, has been very fully expounded in the published works of Dr. Henry Fairfield Osborn (*Origin and Evolution of Life*, 1918). That parallel evolution has been potent in the order of mammals to which man is assigned there can be no doubt. The monkeys of the New World parted company from those of the Old early in the Eocene period; it is probable that at the time of their separation they had only reached the stage represented by the Tarsioids, a family of monkey-like primates, which has now only one living representative—the Tarsier (*Tarsius spectrum*) of Borneo and other islands of the Malay Archipelago. Although parted thus early, New and Old World monkeys have acquired corresponding structural modifications—modifications of a kind which we cannot regard as having been present in their common ancestor. The brain of the South American spider monkey (Ateles), that of the Old World monkeys of the semnopithek type, and that of the small anthropoid or gibbon, have many common characters which could not have been present in the brain of their Eocene ancestor.

We may legitimately infer, however, that a bias or tendency to produce similar or almost identical modifications was latent in the common ancestor. If parallel evolution has been at work in one section of the order of primates it may have been at work in another, and we must therefore keep in mind the possibility that man and the gorilla may have acquired their many and striking points of structural similarity independently. Cope (1882) and Hubrecht (1897) supposed that human lineage had parted from that of the anthropoids near the base of the primate phylum; if this were so man would have an independent pedigree of immense length. In more recent times Prof. F. Wood Jones (*The Problem of Man's Ancestry*, 1918) has put forward the theory that man, because of the number of primitive and generalised features of his structure, is to be traced back to an independent origin from a tarsioid ancestor. Such a view entails the need of supposing that the multitude of structural similarities shared by man and the great anthropoids must have been acquired by each independently—a supposition which is unacceptable to the majority of those who have made a special study of the higher primates living and extinct.

Klaatsch (*Die Stellung der Menschen im Naturganzen*, 1911), (*Evolution and Progress of Mankind*, 1923) made a larger demand on the powers of evolution to reach the same end by diverse routes. This voluminous author traced the origin of mankind to an anthropoid ancestry, but supposed that the ancient inhabitants of Europe—Neanderthal man, known only from his fossil remains, and the living Negro peoples of Africa had arisen from the same stock as the gorilla and chimpanzee, while Mongolian peoples and men of the modern European type had sprung from the same lineage as the orang. Klaatsch believed in the polygenetic origin of human races, whereas nearly all modern authorities hold a monogenetic theory of man's evolution. They cannot believe that black and white races, which although outwardly dissimilar are yet structurally so alike and freely capable of interbreeding, could have sprung from different branches of the primate tree. They rely on the axiom that likeness in structure means similarity of descent.

Man an Aberrant Primate.—In charting the family tree of the Higher Primates modern authorities differ as to the position which should be assigned to man. Prof. Eugène Dubois represents the human stem as the main and direct continuation of the trunk of the primate tree (*Nature*, vol. 53, p. 245, 1896): from this main trunk all the other members of the primate order re made to come off as side branches. Man is given the central osition of his order; he forms the apex of the primate tree. Prof. lliot Smith (*Evolution of Man*, 1925) also gives the human amily the central position as a direct continuation of the main rimate stem. In reality man is the most aberrant member of is order; in brain and in the modifications of his lower limbs he as departed farther from the ancestral primate state, so far as e know that state by the study of fossil remains, than any member of the order; he has retained less of the structural organisaon of the original primate than all the others. Apparently in he evolution of the higher primates there has been the same endency as is to be noted in modern political parties—a tendncy for an extreme wing to move ever further from the central roup of conservatism. The human family represents the exreme wing in the order of primates; *Tarsius*, greatly modified s it is, retains the essentials of the central or conservative group.

MAN'S ZOOLOGICAL POSITION

Zoologists classify animals into families, sub-families, genera nd species, according to their degrees of structural likeness; hey presume, although fully aware that parallel evolution can nd does take place, that two animals, such as the gorilla and himpanzee, which are so similar in the structural details of their odies, owe that similarity to their descent from a common anestry. Darwin urged rightly that in settling the zoological elationship of one group of animals to another, more weight nust be attached to the points wherein they agree than to those n which they differ.

Huxley's Views.—In the masterly analysis of man's strucural relationships given by Huxley in *Man's Place in Nature* 1863), more stress was laid on the anatomical differences which eparate man from the gorilla than on the points wherein they gree. Huxley held that differences of a like kind and of an qual degree separated the gorilla from any form of catarhine or latyrhine monkey a critic might choose for comparison. He eld that if evolution could produce the structural gap which eparates a monkey from the gorilla it could also bring about the byss which divides the gorilla from man. Huxley's conclusions re still valid; indeed, the modern anatomist is convinced that he structural hiatus which lies between a baboon or any other orm of monkey and the gorilla is much wider than that which es between the gorilla or chimpanzee and man. When tested by nodern methods, the blood of the chimpanzee shows a much loser affinity in its reactions to that of man than to that of any Old World monkey; the blood of monkeys of the New World, hen submitted to the same tests, reveals a still more distant ffinity (Prof. G. H. Nuttall, *Blood Immunity and Blood Relationship*, 1904). Huxley included in one family the great anthropoids (gorilla, chimpanzee and orang), the small anthropoids siamang, gibbons), and the various genera of monkeys of the Old World; if we are to be guided by anatomical considerations e must give to each of these groups the rank of a family. The ame rank—that of a primate family—must be given to the ection which embraces all the various races and types of mankind, living and extinct. The various genera of New World nonkeys make up a fifth family of primates.

The Primate Families.—Thus in that part of the living animal ingdom to which man belongs, there are five families—the uman family, that of the great anthropoids, that of the small nthropoids, the family of catarhine or Old World monkeys and he family of platyrhine or New World monkeys. These families re separated by structural gaps of about equal magnitude. rom the platyrhine monkeys upwards, these families form an scending series in the sense that each succeeding family marks further departure from the ancestral tarsioid type, the point f highest differentiation being reached in the human family.

EVIDENCE OF MAN'S DESCENT

Anatomical.—The members of these five families of primates ave a common structural substratum—an inheritance from the ncestral stock from which they have all descended. Each amily in the course of evolution has come by anatomical features which are peculiar to itself. A full analysis of the structural details of man's body shows that about 30% of them are peculiar to himself. The corresponding characters of the gorilla number 16%; the gibbon has about the same proportion of features peculiar to its own family (Keith, *Rivista di Antropologia*, vol. 20, p. 1, 1916). As examples of man's peculiar characters we may cite his nude skin, his projecting nose with well marked wings, the size of his brain, the strength of his thigh, the form of his leg, the shape of his foot.

Common Characters.—Further analysis reveals in man's body a series of characters which he shares with only two other living animals—namely, the gorilla and chimpanzee. These amount to nearly 9% of the total points selected for comparison, but if we include in this group features which man shares with the gorilla alone or with the chimpanzee alone, then man has in his body about 26% of characters which he shares with gorilla and chimpanzee or with gorilla alone or chimpanzee alone. Such characters, we presume, are derived from a common ancestor which gave birth to man and to the great anthropoids of Africa. As examples of characters common to the three we may cite the air chambers which branch off from the nasal cavity. These have the same arrangement and are of the same number in man, gorilla and chimpanzee. Another example is to be found in the small bones of the wrist. Of the higher primates, only in these three has the *os centrale* disappeared as a separate unit from the carpus; yet in a foetal stage this bone is present in all three; and as a separate element in adults of all the other higher primates.

Descending still lower in the strata of human anatomy we encounter a group of characters which man shares with the three great anthropoids. We may speak of man and these three as the giant primates, for compared with the earlier types they are giants, or we may apply to this group Haeckel's convenient name—*Lipotyla*. Man shares with the other giant primates 10% of similarities of structural detail; to this we may add 5% which he shares with the orang and with the orang only, characters which the chimpanzee and gorilla have apparently lost or perhaps never possessed. Going still lower in our analysis, we find over 8% of characters which are common to the gibbon as well as to the great anthropoids. With the gibbon man shares 8% of structural features which are not to be seen in the bodies of the great anthropoids. In this case, again, we have to suppose that man and the gibbon came by those characters long after they separated from a common ancestor, or that the great anthropoids have lost them in the course of evolution while man and the gibbon have retained them.

Lower in the scale of our analysis we come upon features in man's body which he has apparently retained from a catarhine ancestry; at least, to find their counterparts we have to go to the bodies of Old World monkeys. In man's body there are 5% of such catarhine features; in the gorilla's body such features are three times as numerous. It is remarkable that platyrhine characters, features to be seen in the bodies of the New World monkeys, should be as numerous as catarhine in man's body.

There is a small residue of anatomical details in human anatomy attributable to a still more distant past, a heritage from a tarsioid or lemuroid ancestry. From the details revealed by anatomical analysis it is plain that evolution has not proceeded in an orderly or simple manner in shaping the bodies of the higher primates; characters are curiously scattered. Yet to explain the distribution of characters in the various families we must suppose that man's ancestry is linked closely to that of the African anthropoids—the gorilla and chimpanzee. In some instances we obtain help in explaining the distribution of characters by calling in the aid of *collateral* or parallel evolution; in other cases Mendel's discoveries in heredity assist us; further, we see that the body of man and of ape is a great mosaic work of structural elements and that progressive changes may occur in one set of units while retrograde changes affect another set.

In recent years the formation of the human embryo in the womb, the complicated changes which transform the embryo into a foetus and the elaborate processes which produce the organs of the ripe child from embryonic rudiments, have been studied by an ever-growing army of inquirers and by methods which show an ever-increasing precision. Embryologists find it necessary to assume that the law of evolution holds for man; unless they make this assumption they can offer no rational explanation of the complex changes which engage their attention. In its broad lines development pursues the same course in the human body as in that of all vertebrate animals. What Francis Balfour in 1885 saw taking place with diagrammatic clearness in the embryo of the dog-fish has given clues to the more complex and obscure processes now known to occur in the embryo of man.

The developing human egg, when it becomes established in the mother's womb, undergoes a series of elaborate and peculiar changes. The investigations carried out by the late Dr. Emil Selenka (*Menschenaffen. Studien über Entwickelung und Schädelbau*, 1898–1906) revealed the fact that only in the wombs of four other living mammals, the gorilla, chimpanzee, orang and gibbon, do the same changes take place. The process by which the placenta is formed, thus establishing a means of supplying the unborn child with nourishment, is exactly the same in man as in anthropoid apes. It is true that in *Tarsius* we see outlined the basal plan of placentation met with in the higher primates, but it is also true that in the placentation of the monkeys of the Old World and also in that of the New World we see a stage which leads on from the lower or tarsioid condition to the higher or anthropoid form. In the embryos of man and of the anthropoids an external jointed tail is produced in the fifth week of development; by the end of the eighth week it has shrivelled and become submerged, leaving a dimple at the point of the caudal region where it sinks below the surface. These are a few examples of some of the remarkable similarities which link the embryological history of man with that of the anthropoid apes.

Recapitulation, Interpolation, Adaptation.—When in the later decades of the 19th century anatomists applied themselves to unravelling the development of man's body, they expected it to recapitulate, in full detail, the various stages of his evolution. In this they have been disappointed, because in the growth of the embryo and of the foetus we see three different processes at work. We see recapitulation taking place; we also see new characters being interpolated from the time the embryo makes its first appearance until all the parts of a formed child are laid down; further we see at every stage the body of the embryo and of the foetus being adapted to a life within the womb. When gill-clefts appear in the neck of the human embryo towards the end of the first month of development we see a recapitulatory and very distant phase exemplified. When we look at the developing human foot, with the expectation of finding an anthropoid phase, we search in vain. The great toe is never a free and separate member in the human foot as it is in the adults of all other primates. There is a stage in the development of the feet of primates when all the digits diverge equally from the tarsal base; man and ape pass through this stage and man clings to it as it were, whereas all the other primates pass on to a final prehensile stage. Yet in the sole of the newly born child we see the same flexion lines as in that of the gorilla; we find the same muscles in the great toe of the human foot as in that of the gorilla; we find the joint at the base of man's great toe, especially in the foetus, moulded in the same form as the gorilla. We cannot explain these appearances unless we believe that the human foot has been evolved from one like that of the gorilla, more especially as the foot of the gorilla shows a curious blend of human and monkey-like features.

The human great toe does not recapitulate ancestral history; developmental changes which mould the great toe into the human pattern set in just when the simian ones are due; the human changes do not succeed but replace those that give the ape its prehensile foot. New changes have been intercalated in the evolutionary sequence. In a multitude of details the human embryo no longer recapitulates the series of changes gone through by its ancestors. It is true of every part of the human body; human characters begin to peer through its higher primate qualities before development is a month old.

Of the changes which affect the developing human body those which represent adaptations to life within the womb are the most important. The child draws its living from its mother's body; it is sheltered and kept warm; it has not to seek its living nor defend itself; such qualities need not be attained until the time of birth; until then nature is free to work out what experiments she will. It is a remarkable fact that many of man's distinguishing features are to be met with during foetal stages in the development of anthropoid apes. A stage which is transient in the foetal ape becomes permanent in man. We may take as an example the comparative hairlessness of man's body. A foetal chimpanzee, in the eighth month of development, resembles a human foetus of the same age; both have hair growing freely on their scalps, but the rest of their bodies, although provided with lanugo, appear to be nude. By birth the chimpanzee's body is covered with hair, but the human child retains the foetal state. Yet all known primates save man have their bodies thickly covered with hair; hairlessness is not an ancestral condition, but one made possible by the retention of the young in the shelter of the womb. The skin provides us with another example of foetal inheritance. In the fair or white stock of mankind the skin has become relatively free from pigment. In their earlier stages of foetal development apes are unpigmented; they darken as the time of birth approaches. White men have come by their colouring through the inheritance of a foetal condition, one which is certainly not ancestral.

Many examples might be cited of man coming by distinctive characters by retaining foetal states, but the following may be taken as representative. In all foetal primates the brain is relatively large and the jaws absolutely small; this is certainly not an ancestral state, for in all the older forms of primate the brain is small and the jaws large. Man is distinguished by the large size of his brain and the relatively small size of his teeth and jaws. How he compares with adults of great anthropoid apes may be seen from the following data. We may take the capacity of the cranial cavity to represent the size of brain and the area of the palate to represent the size of the jaws. In a well-grown adult European male we expect a cranial capacity of 1,500 c.c. and a palatal area of 25 sq. cm., there being 60 c.c. of brain space for every square centimetre of palate. The average male gorilla has a cranial capacity of 470 c.c., a palatal area of 72 sq. cm., that is 5·8 c.c. of brain space for every square centimetre of palate. The corresponding figures for the average male orang are: 412 c.c., 62 sq. cm., giving a cranio-palatal ratio 6·6:1; in the average male chimpanzee the figures are: 390 c.c., 46 sq. cm., giving a ratio of 8·5:1. There is a wide gap between the European cranio-palatal ratio 60:1 and that of the chimpanzee, 8·5:1. We may fill the gap somewhat by citing a Tasmanian skull with a capacity of 1,350 cc., a palatal area of 36·7 sq. cm., and a ratio of 36·7:1.

We find a still nearer approach to the anthropoid condition in the fossil skull of Rhodesian man in which the cranial capacity is 1,300 cc., the palatal area 41 sq. cm., the cranio-palatal ratio 31·7:1. Even this ratio is far above that of the chimpanzee, 8·5:1; but if we take a suckling chimpanzee, in which the cranial capacity is 260 c.c. and the area of palate 13·6 sq. cm., we obtain a ratio 19:1, an approach to the human proportion. If we take a still earlier stage, such as may be observed in a chimpanzee foetus during the eighth month of development, we find a ratio which is human in its magnitude. Man has come by his small palate by retaining a foetal anthropoid condition, and this is true of all the parts of man's skull which are concerned in mastication. This tendency to foetal inheritance is not confined to the human branch of primates; in certain genera of New World monkeys, particularly in Chrysothrix and Cebus, we see in their small jaws and large heads the same law at work.

The belief that many of man's foetal characters do not reflect ancestral stages, but foreshadow the trend of future evolution, was held by several anatomists in Germany towards the end of the 19th century, particularly by Ranke. The law of foetal inheritance, so far as it relates to man, has been greatly extended during recent years in a series of papers by Prof. L. Bolk of

Amsterdam (*Proc. of the Roy. Acad. of Sc. of Amsterdam*, 1921–5).

Embryological evidence, if it has failed to reveal the pithecoid states through which man has passed in his ascent, does provide conclusive evidence of his simian ancestry. In the development of his brain, for example, we see that the first fissures to appear are those which occur in the brains of the higher monkeys; the next are those which are found in the brains of the great anthropoids, and later still the secondary human sulci are formed; but never at any stage does the human brain correspond to that of monkey or of anthropoid. If embryology has failed to reveal the details of man's history, it has shown that the processes of evolution are at work on the foetal body; if the study of the foetus does not help us to decipher man's past, it does seem to provide a basis on which we may forecast the future of the human body. The brain of the gorilla, in the totality of its characters, is the most like that of man; these two are structural allies, yet evolution has moulded their bodies in opposite directions. During growth the gorilla replaces all its foetal characters by those of brutality and strength; in man the tendency has been to retain the delicate physique of the young and to shed those of a more brutal nature. Why the one fate overtook the gorilla and another fell to man remains an enigma.

BIOLOGICAL EVIDENCE OF MAN'S EVOLUTION

Blood Tests.—Not only are the bodies of man and anthropoid apes fashioned on similar lines, but, as was demonstrated at the beginning of the present century, their living tissues give like reactions. In 1900 Dr. Hans Friedenthal injected a small amount of human blood into the veins of a chimpanzee; its vital qualities were so similar to those of the chimpanzee that no disturbance followed the operation. When an equal amount of the blood of a macaque monkey was injected into the veins of the chimpanzee there was a slight reaction; the corpuscles of the macaque's blood were destroyed and ejected by the kidneys. When the blood of an ox was used a violent reaction was produced, the foreign blood being destroyed and thrown out.

Prof. G. H. F. Nuttall, of Cambridge University, thereafter elaborated a more precise method of estimating blood-affinities, by which very small quantities of blood can be tested against specially prepared antisera. In 1904 appeared his classical work *Blood Immunity and Blood Relationship*, containing the results of tests carried out on three species of anthropoid ape, 28 species of Old World monkeys, and nine species from the New World. The blood of all these species was tested against a human antiserum. The blood of the anthropoids gave a full reaction—100%; that of the Old World monkeys gave a lesser reaction or precipitation, one equivalent to 92% of the full; that of the New World monkeys 78 per cent. At the time Prof. Nuttall was making these investigations in England, Dr. Uhlenhuth was carrying out independent inquiries in Germany, and reached corresponding conclusions as to degrees of affinity. The tests devised by Nuttall and by Uhlenhuth utilise the fluid or serum of the blood. Recently Drs. Landsteiner and Miller (*Jour. Experim. Med.*, vol. 42, p. 841, 1925) have utilised the corpuscular elements of the blood and find that they give more delicate reactions than those given by the serum. They devised tests which serve to distinguish the blood of the chimpanzee from that of man, but which failed to discriminate the blood of the white man from that of the negro.

Disease Reactions.—The reactions of living tissue are also tested by disease. Man is peculiarly susceptible to syphilis; the animals most akin to him in this respect are the great anthropoid apes. Monkeys are difficult to inoculate with syphilis, and when they suffer, take the disease in its mildest form. Anthropoid apes are almost as suceptible to typhoid fever as man is. When chimpanzees are kept in confinement they are liable to that modern disease of man—appendicitis. Anthropoids react to stimulants, sedatives and poisons in the same manner as human beings. The brains of the great anthropoid apes are smaller and are less convoluted than is the case in man, yet when the living cortex is stimulated by electrical methods, be it in man or anthropoid ape, the same reactions follow when corresponding convolutions are excited. Surgeons have found that observations made by experimental physiologists on the brains of anthropoid apes afford reliable guidance when they have to operate on the brain of man. Thus the evidence supplied by vital tests bears out the conclusions forced on anatomists by similarity of structure—namely, that great anthropoid apes, in an evolutionary sense, are near akin to man.

EVIDENCE OF VESTIGIAL STRUCTURES

Nearly all the structures which have become greatly reduced or are mere vestiges in the body of man have undergone a similar fate in the bodies of the anthropoid apes. In them as in man the tail has disappeared, all save its basal part, which has sunk beneath the surface to form the coccyx. It is true that the vermiform appendix of man is smaller than that of any of the anthropoid apes, and that in half of the Europeans who reach the age of 70 its lumen has become closed, yet it is more than doubtful if this structure should be reckoned vestigial in the body of either man or anthropoid. The *palmaris longus*, the *plantaris*, the *pyramidalis*, muscles which are reduced or fibrous in man, are in the same state in anthropoid apes. Such evidence points to a common origin for anthropoids and man, but it throws no light on man's more immediate relationship to any member of the anthropoid group.

There are two muscular vestiges, however, which point to man's kinship to the African anthropoids. There is a muscle in the neck of monkeys which helps to lift the shoulder; it is called the *levator claviculae*. It has almost disappeared from man's body; it is met with only once in a hundred dissections. This muscle shows definite signs of reduction in the gorilla and chimpanzee, but not in the orang or gibbon. All monkeys have a strong muscle called the *latissimo-condyloideus*. When a monkey is climbing, and has seized a branch with its hand, it uses this muscle to pull the trunk upwards. It is a particularly strong muscle in the gibbon, well developed in the orang, somewhat reduced in the chimpanzee, partly fibrous in the gorilla, wholly fibrous in man, although in 5% of human bodies some muscle fibres may be detected. Lately Dr. A. H. Schultz, of the Carnegie Institution of Washington, has found a remarkable example of the persistence of a vestige in man's body (*Amer. Jour. Physic. Anthrop.*, vol. 7, p. 149, 1924). Lemurs, which branched off from the primate stem at a very distant geological period, have a tuft of touch vibrissae at the wrist. Monkeys were supposed to have lost these vibrissae; Dr. Schultz found them in foetal stages of monkeys both of the Old World and of the New. On examining the wrists of human foetuses in the second month of development he found a raised plaque at the spot where the touch vibrissae are situated in lemurs.

THE EVIDENCE OF FOSSIL REMAINS

Pithecanthropus Erectus.—The discovery which throws most light on the evolutionary progress of man was made in Java during 1891–2 by Prof. Eugène Dubois, then a surgeon in the colonial military service, and later professor of geology in the University of Amsterdam. In a stratum which contained the fossil bones of many extinct species of animals he obtained five fragments of a strange kind of being, one which he regarded as a transitional form between man and ape—a real missing link. He named it *Pithecanthropus erectus*, and assigned it to a separate family of primates—one lying on the borderline between anthropoids and man. (*Pithecanthropus erectus, eine menschenaehnliche Uebergangsform aus Java*, 1894.) The five fossil fragments found were: a skull cap which outwardly had the form which might be expected in a giant form of gibbon, a left thigh bone and three teeth. The most distant of the fragments were twenty paces apart. Later he added a sixth fragment—part of a lower jaw found in another part of the island but in a stratum of the same geological age. The skull cap is flat, low and has great eyebrow ridges; its characters are more simian than human, yet when Prof. Dubois succeeded in obtaining a cast from the interior of the skull cap, that cast bore on it the convolutionary pattern of the brain of Pithecanthropus, and that pattern proved to be altogether human. Pithecanthropus, the fossil man of Java, had a brain which was smaller, simpler and infinitely more primitive than that of the lowest living men.

By this discovery Prof. Dubois caught the human brain in the act of evolving. Certain cortical or convolutionary areas in man's brain are known to be concerned with sight, hearing and touch, and the reception of messages from other sense organs; a "motor" area is concerned in the initiation and control of voluntary movements. Between these primary areas of the cortex lie association areas which have to do with the memory and the interpretation of what is seen, heard or felt. The cortex of part of the frontal lobe—the prefrontal cortex—is concerned in the acquisition of skilled movements. These secondary or association areas of cortex, which lie between and separate the primary areas, are the basis of man's educability—his capacity to learn from experience. In the brain of Pithecanthropus the association areas are much less developed than in the brains of the lowest of living human races. Yet all the essentially human parts are represented. It is even possible that the owner of this brain was capable of speech.

A further study of the brain-cast has convinced Prof. Dubois that Pithecanthropus must be placed in the human family (*Proc. Roy. Acad. Sc. Amsterdam*, vol. 27, nos. 5, 6, 1924). The brain of this "fossil" man is now estimated to have had a volume of at least 900 c.c.; the largest-brained gorillas rarely rise above 600 c.c.; the lowest-brained of human beings occasionally falls below 1,000 cubic centimetres. Pithecanthropus in size of brain lies on the verge of humanity. His teeth, if large, are essentially human in form of crown and root; the socket for the canine, in the fragment of lower jaw, shows that this tooth was not massive and pointed as in anthropoid apes. The thigh bone is human altogether, and gives proof that Pithecanthropus walked as men do.

Pithecanthropus was assigned by Prof. Dubois, on reliable evidence, to a date late in the Pliocene period; others on weighing the evidence suppose that he lived early in the Pleistocene period. If we accept the duration of the Pleistocene as 250,000 years, and regard Pithecanthropus as representing the evolutionary stage reached by mankind at the beginning of this period, then we have to conclude that man's body had become adapted to its peculiar posture and gait before the end of the Pliocene period, and that the higher development of the brain took place in the ensuing Pleistocene period.

Eoanthropus.—The discovery which ranks next in importance to that of Pithecanthropus was made by Mr. Charles Dawson at Piltdown, Sussex, between the years 1911 and 1915. He found the greater part of the left half of a deeply mineralised human skull, also part of the right half; the right half of the lower jaw, damaged at certain parts but carrying the first and second molar teeth and the socket of the third molar or wisdom tooth. The lower jaw, on the region beneath the chin, had a bar of bone known as the "simian shelf," which until then had been regarded as a mark of the ape. Later a pointed upper canine tooth was added; its characters were simian rather than human. The stratum of gravel proved to have been laid down early in the Pleistocene period, and it is certain that the fossil fragments of this human skull were as old as the date of deposition. From the fossil fragments thus found, Sir Arthur Smith Woodward reconstructed an extinct genus of mankind, *Eoanthropus*, the dawn-man (*Quar. Jour. Geol. Soc.*, 1913–5). Subsequently (1915) in the deepest part of the gravel stratum there was found a remarkable bone implement hewn from the thigh bone of an extinct kind of elephant; in a neighbouring field two other fragments of a skull of the same kind came to light, and another molar tooth.

Some experts still doubt whether a lower jaw which resembles that of a chimpanzee in several respects should be assigned to a skull which is purely human in its characters. At first there were differences of opinion as to the size and characters of the brain of Eoanthropus. Amongst British authorities there is now agreement that the skull and jaw are parts of the same individual, and that the brain, as revealed by casts taken from the interior of the skull, is human in its size and in all its characters. If we divide living races into three classes according to the size of brain, the large-brained having a cranial capacity above 1,450 cu.c., the small-brained a capacity under 1,350 cu.c., then Eoanthropus certainly reached the upper limits of the small-brained class if not actually a member of the medium-brained group. The brain of Eoanthropus has risen many stages above that of Pithecanthropus; the bone implement affords evidence of manual skill and of inventive ability on the part of its owner. The eyebrow ridges of Pithecanthropus are shaped as in the gibbon, chimpanzee and gorilla; in Piltdown man they are fashioned nearer to the form seen in the skull of the orang. The discovery at Piltdown shows that at the beginning of the Pleistocene period a race of mankind had come by a brain that had reached a human estate, and that this race still retained certain definite simian characteristics in its jaws, teeth and face.

Neanderthal Man.—In 1857 while workmen were clearing out the Neanderthal cave near Düsseldorf, Germany, they found the vault of a fossilised skull and limb bones of a man who proved to be, in the light of further discoveries, a representative of an extinct species of man—*Homo neanderthalensis.* A fossil skull which was dug up at Gibraltar in 1848 is of the Neanderthal type. Fossil remains of the same kind have been found in Belgium (at Naulette, 1866, and at Spy, 1886), but the caves of France have proved the richest source of Neanderthal remains, particularly those in the valley of the Dordogne.

The evidence found at La Chapelle (1908), at La Ferrassie (1909), at Le Moustier (1908) and at La Quina (1911) made it quite clear that this extinct type of man, marked as he was by many simian traits of body, buried his dead with signs of respect. He worked flint implements with great skill, in the style or culture known as Mousterian. He was a hunter and lived in caves and rock shelters. His molar teeth were often shaped in a peculiar manner; his teeth have been found in cave deposits in Jersey (1911) and in Malta (1917). His remains have been found in Moravia (1906) and at Krapina in Croatia (1899–1906). His culture has been found in Italy and in England, but no trace of his body. Only once have fossil remains of Neanderthal man been found outside the limits of Europe, in a cave situated on the western shores of the Sea of Galilee (1925).

Neanderthal man appears to have been the sole occupant of Europe during the middle of the Pleistocene period—throughout the time in which the Mousterian culture prevailed in that continent. The date of this culture may be put down tentatively as extending from 40,000 B.C. to 20,000 B.C.; perhaps its duration was much longer. Remains of Neanderthal man rather more primitive in type, and found in strata older than the Mousterian strata of France, have been discovered at Taubach (1895) and at Ehringsdorf (1914), both of these sites being near Weimar, Germany. *The Heidelberg mandible* was found at a depth of 78 ft. in a sandpit at Mauer, ten miles to the east of Heidelberg, in 1907. The stratum in which it was found belongs to the deeper and older Pleistocene series; this fossil jaw thus represents a race which lived long before the men who practised the Mousterian culture. Yet so like is the mandible of Heidelberg man to that of Neanderthal man, in the majority of its characters, that we may safely regard him as an ancestral representative of the Neanderthal species. In Heidelberg man the canine tooth did not project above its neighbours as in Eoanthropus.

At one time it was believed that Neanderthal man represented an ancestral phase of modern man. Every bone of his body shows distinctive markings, many of these being of a simian nature. His eyebrow ridges were like those of the gorilla and chimpanzee; the roof of his skull was low like theirs, and yet in size of brain he equalled, if he did not surpass, modern Europeans. He had, however, certain specialisations of structure which modern or Neanthropic man does not possess. Besides, the archaeological evidence is now complete that he was replaced in Europe by the arrival of men of the modern kind—represented by people of the Cromagnon type. For these reasons Neanderthal man cannot be regarded as an ancestor of modern man. Neanderthal man and men of the modern type, however, have so much in common that they must be looked upon as descendants of a common ancestor.

Rhodesian Man.—The fossil remains of Rhodesian man which were discovered in the Broken Hill Mine, Northern Rhodesia, in the summer of 1921, also bear evidence to the truth of man's evolution. His fossil remains lay deep in a filled-up cave; he was probably alive in Africa when men of the Neanderthal type dominated Europe. His limb bones show that he was tall, quite 5 ft. 10 in. in height, and stoutly made, after the manner of modern man. His skull, which is complete save the lower jaw, possesses many primitive traits. His brain space was small (1,300 c.c.); in point of development the brain falls below that of Eoanthropus. The eyebrow ridges are extremely massive, and the face has features which recall those of the gorilla. Yet his teeth, although large, are human in every respect and were ravaged by caries. Rhodesian man might well stand as an ancestral type to modern man.

Cromagnon and Other Races.—The Cromagnon type of man and other forms which appear in Europe after the disappearance of Neanderthal man are fully developed men of the modern type; they differ from us only in robusticity of build and strength of jaw. The fossilised, capacious skull discovered at Boskop, Transvaal, in 1913, represents an extinct form of man of the Bushman type. The Talgai skull, derived from a Pleistocene deposit and described by Dr. S. A. Smith (*Phil. Trans.*, ser. B, vol. 208, p. 351, 1918), is of the same form as that of living Australian aborigines, but possesses additional primitive features. Prof. E. Dubois discovered a Pleistocene form of man at Wadjak, Java, one with a very large cranial capacity (*Proc. Roy. Acad. Sc. Amsterdam*, vol. 23, pt. 7, 1920). Such discoveries, although they bear out the truth of evolution, do not throw light on man's evolutionary pedigree.

GEOLOGICAL EVIDENCE OF MAN'S ANTIQUITY

Artefacts in Pliocene Deposits.—If we accept Pithecanthropus as representative of man's estate towards the end of the Pliocene period, then we must infer that man had come by his posture and his gait before the close of the Pliocene period, and that his brain underwent its greatest expansion in the earlier part of the Pleistocene period; an inference which postulates a rapid rate for human evolution. In size of brain Pithecanthropus was approaching the human minimum. It is difficult to conceive him as a maker of tools, yet in geological deposits which were laid down in East Anglia during the Pliocene period Mr. Reid Moir has found flints which must have been shaped by beings which possessed skilled hands (*Pre-Palaeolithic Man*, 1921, *The Great Flint Implements of Cromer*, 1923). Such evidence indicates that other genera of the human family may have marched towards the human goal more rapidly than Pithecanthropus.

The Early Anthropoids.—If man is a descendant of a great anthropoid, and the great anthropoid of a small, then a knowledge of the geological levels at which these two forms occur should throw some light on the date of man's evolution.

The oldest trace of a small anthropoid so far discovered comes from strata of the Fayum, Egypt, laid down in the earlier part of the Oligocene period. The half of a lower jaw with its teeth is all that has been found of this small anthropoid, which was described by Von Schlosser in 1911. He named it *Propliopithecus*, and regarded it as an ancestral form of gibbon (W. K. Gregory, *The Evolution of the Human Dentition*, 1922).

No fossil remains of great anthropoid apes have been found in strata older than those of the Miocene period. Of Miocene great anthropoids, at least nine species have been discovered; one of them, *Sivapithecus*, known from fragments of jaws and teeth found in the Siwalik deposits of India, is regarded as a possible ancestor of man by Dr. G. E. Pilgrim, but a full consideration of the evidence leaves the expert unconvinced. In 1922 a tooth was found in Pliocene beds of Snake Creek Quarry, Nebraska, which has been attributed to an anthropoid ape with human leanings to which the name *Hesperopithecus* was given by Dr. Henry Fairfield Osborn. Unfortunately, the tooth was worn and its true characters hard to decipher; the fact, however, that such competent authorities as Dr. Osborn, Dr. W. K. Gregory and Dr. W. D. Matthew are convinced that a trace of a humanoid anthropoid has been found in America will secure consideration for Hesperopithecus.

Early in 1925 Prof. Raymond Dart announced the discovery of the fossil skull of a young anthropoid ape, found in a limestone quarry at Taungs, on the eastern border of the Bechuanaland Protectorate, near the Transvaal frontier (*Nature*, 1925, vol. 115, p. 195). The geological evidence goes to show that this anthropoid, which Prof. Dart named *Australopithecus*, cannot be older than the beginning of the Pleistocene period, which eliminates it from any place in the line of man's ancestry. Its anatomical characters place it in the same group of anthropoids as that to which the gorilla and chimpanzee belong. In some respects Australopithecus is more human than either of the two living African anthropoids.

Summary.—Thus, taking all lines of evidence into consideration, anatomical, biological, embryological and geological, we are led to the conclusion that man has been evolved from a lower form, and that human races, as we know them to-day, are the products of evolutionary processes. There remain great blanks in the line of evidence which links the origin of modern man to an extinct form of anthropoid ape. Between the highest kind of anthropoid and the lowest type of man, represented at present by Pithecanthropus, there remains a great gap; the transitional forms which fill this gap still remain to be discovered. Yet the evidence as it stands, imperfect as it is, points to man's departure from an anthropoid status early in the Miocene period, certainly 1,000,000 years ago, perhaps more; that in the Miocene and Pliocene periods his body and limbs became adapted to a plantigrade posture; that his brain underwent expansion in the Pliocene, and particularly in the earlier part of the Pleistocene period, and that as the brain reached a full human status the coarser outward appearances of the ape were shed. Of the vital processes which brought about these changes we are as yet ignorant, but it is manifest that in his evolutionary progress man has tended to acquire and preserve in adult years states which appear at first as transient conditions in foetal or infantile stages.

It is becoming clear that the machinery of evolution is that which regulates development and growth, and in these matters knowledge is growing. Experimental embryologists have proved that one group of developing cells can and does regulate the growth and behaviour of a neighbouring group. The theory of hormones has thrown a flood of light on the machinery of evolution (Prof. Chas. R. Stockard, *Publications of Cornell University Medical College*, 1924, vol. 10; Keith, *Supplement to Nature*, Aug. 18 1923). It has been proved that substances or hormones are carried by the circulation throughout the living body from a series of glands which include those of reproduction, the adrenal, the thyroid, the pituitary and pineal, and that the substances thus liberated in the body do control its vital reactions and its structural form.

MANAGEMENT: *see* SCIENTIFIC MANAGEMENT.

MANCHESTER, England (*see* 17.544), has an area of 21,688 ac. (including areas incorporated in 1910 and 1913), and an estimated population of 761,320. Since 1918 10 members have been returned to Parliament, and the city was brought entirely under one board of guardians in 1915 and one board of overseers in 1916. The birth-rate varied between 1·86 and 2·37 in 1921–5, and the death-rate between 1·36 and 1·44.

Housing and Improvements.—Several housing schemes, including a number of wide new roads, have been undertaken, the largest being at Blackley, Moston, Wilbraham Road, Anson and Gorton, but the house shortage was still acute in 1926, although more than 5,300 houses had been built by the municipality since 1919, besides those erected privately. The council aim at completing 10,000 more by 1930, and had under consideration the question of the purchase of a site of 4,500 ac. in rural Cheshire beyond and to the south of the city limits. In this area stand the Wythenshawe Hall and grounds (comprising 250 ac.), presented to the corporation for park purposes. A number of large parks and open spaces have been acquired, and include Cringle Fields, Burnage (54 ac.); Broadhurst Park, Moston (84 ac.); Fletchermoss Playing Fields, Didsbury (21 ac.); and Green Bank Fields, Levenshulme (24 ac.). New parks are planned for Withington (48 ac.) and Chorlton-cum-Hardy (37 ac.), which have grown rapidly since the World War.

New Buildings.—The Horsfall education museum, Ancoats Hall, has been transferred to the corporation; the old parsonage, Didsbury, was opened as a branch art gallery in 1923; and Platt Hall was handed over in 1925 as a branch art gallery and museum. A new art gallery, surrounded by a wide, open space, for which the design was approved in 1925, is to be built on the site of the old Royal Infirmary in Piccadilly. The infirmary has been moved to Oxford street, and several other hospitals have been built in its vicinity. A large Wesleyan hall and institute was opened in Peter street in 1910, the Y.M.C.A. building in 1911 and the Church House in Deansgate in the same year. The Exchange was extended and reconstructed in 1914–21; the historic Free Trade Hall in Peter street was bought by the corporation in 1921, and plans were made in 1925 for the extension of the town hall, to include the central library, then in temporary buildings on the Piccadilly site.

The new office being erected in King street in 1926 for the Ship Canal Co. will be the highest commercial building in the city. A textile institute, with its headquarters at St. Mary's Parsonage, was founded in 1910; and a British Cotton Industry Research Assn., with offices and laboratories at Didsbury, in 1919. Premises are to be built at Fallowfield for the grammar school. A radium institute, the first in the country exclusively for the use of radium in hospital treatment, was opened in Nelson street in 1921. A statue of King Edward VII. was unveiled in Whitworth Park in 1913, one of Abraham Lincoln in Platt Fields in 1919 and a large war memorial on the foundations of old St. Peter's church in 1924. Playing fields and a pavilion have been acquired at Stretford as a memorial to men of the Manchester Ship Canal Company.

Public Works.—Two additional pipe-lines have been laid from Thirlmere, and the North Cheshire Co.'s water undertaking was purchased in 1921. In 1925 a beginning was made with the large Haweswater scheme, to involve 84 m. of aqueducts, tunnels and pipes. It is hoped to finish the work by 1934. A new electric power station was opened at Barton in 1923, and in 1925 it was decided to double its capacity. Parliamentary powers were obtained in 1921 for the construction of a large gas-generating station at Partington, and the present stations in the city will eventually be used only for distributing. Parliamentary powers were also obtained, in 1911, for a comprehensive scheme to result in the whole drainage of Manchester being carried to works at Davyhulme. In 1925 the possibilities of an electric underground railway were under discussion.

Port Improvements.—In 1925 there were eight docks with a water area of 120 ac. and 5¾ m. of quays in the port. Trafford Wharf was rebuilt and re-equipped in 1924, and in 1925 the last five miles of the Ship Canal were being deepened to allow vessels drawing 28 ft. to come up to Ellesmere Port. Road and railway improvements were also in hand at Ellesmere Port, which is leased by the Ship Canal Co., more wharves are to be built, and the company have acquired 1,000 ac. of land for industrial development. The corporation have determined to undertake a comprehensive civic survey. When the survey has been completed, recommendations will be made as to future action in matters municipal, social, economic, housing, parks, recreation facilities, commerce, industry, communications, and transportation.

Though best known as the business and warehousing centre of the cotton industry, Manchester has also become a great manufacturing and distributing centre for chemicals and dyes, and is one of the chief ports for importing oil. Some of the greatest engineering workshops in the world are in the city or its immediate neighbourhood. Motor-cars and commercial vehicles are made, and rubber manufacture and the ready-made industry are extending. (O. J. R. H.)

MANCHESTER, VICTORIA UNIVERSITY OF (*see* 17.545).—The development of the University of Manchester during the 20th century, in common with that of the other English universities, has been greatly affected by the War. At the same time, valuable contributions both to the defence of the country and to knowledge were made, especially by the scientific, technological and medical staffs who were called upon to face problems raised by the War. The number of students, which had reached 1,691 in 1910, increased immediately after the conclusion of hostilities, and in 1920 was 2,900. It had in 1926 apparently stabilised itself at about 2,500. Perhaps the most significant feature of this increase was the continued growth of the number of women students—730 in 1926 as against 336 in 1910. The botanical and physical laboratories and the extensions of the museum and library, completed during the four years 1910–4, were followed by the erection of a building to house most of the departments of the faculty of arts (1919), while new accommodation was provided for the metallurgical department, and the medical school was internally reconstructed. The continued growth of the library, which contains over 200,000 volumes, led to further extension, and a bequest of Mr. Jesse Haworth made possible the erection of a new wing of the museum, to provide galleries for the exhibition of the valuable ethnographical collections made by the late Mr. Charles Heape and presented by him to the university in 1923.

Developments.—An appeal for funds in 1919 produced a sum of £250,000, and this made it possible to satisfy some of the needs rendered urgent by post-War conditions. New chairs have been instituted in Russian and Italian, in addition to a second chair of French. The lectureship in textile technology has been raised to the status of a professorship, and a similar development has taken place in psychology and in commerce and administration. A chair in English language has been instituted in addition to that in literature, and the second chair in law and the chair of comparative religion have been revived. The institution of a faculty of education in 1914, with a post-graduate degree of master in education, led to interesting researches in educational method and administration, and the faculty received a valuable addition by the endowment by Sir James E. Jones of a lectureship in the training of teachers of the deaf. The same donor also endowed a hall of residence primarily for the accommodation of women students preparing for the certificate instituted in that subject. A gift from the Carnegie United Kingdom trustees led to the establishment of a special library available for teachers and others interested in the education of the deaf.

The university athletic grounds have been extended. They now cover 28 ac. and possess a finely equipped pavilion. The facilities for the residence of the men students have been increased by the recognition of two more halls; while for women students three new halls have been recognised, and the existing Ashburne Hall has been extended to accommodate about 130 students. This extension, opened in 1925, includes a central block, providing a large hall, and beneath it a library in which have been placed the 8,000 volumes bequeathed by Lord Morley for the use of women students of the university. Closer relations between the university and the local education authorities have been established. There are three county and eight municipal authorities contributing annual grants.

The resignation of Lord Morley as Chancellor of the University took place just before his death in 1923. The Earl of Crawford and Balcarres was elected as his successor. Sir Henry A. Miers, previously principal of the University of London, and appointed vice-chancellor of the University of Manchester in 1915, retired during 1926. Mr. W. H. Moberly, principal of University College, Exeter, was appointed to succeed him.

MANCHURIA (*see* 17.552).—In 1911 an agreement was concluded by the "Four Nations" consortium, to finance the development of Manchuria, but was blocked by Russia and Japan until their participation under conditions which secured to them continuance in their privileged position had been conceded. A treaty in 1911 and an agreement in 1916 further strengthened Russia's position in North Manchuria, while the formal annexation of Korea by Japan in 1910 placed the numerous Koreans in Manchuria under Japanese consular jurisdiction. By the beginning of 1911 the "peaceful penetration" of Manchuria and Eastern Inner Mongolia was proceeding steadily and under conditions generally similar to those which had characterised Russia's forward policy from 1898 to 1905.

In 1912 the railway from Changchun to Kirin was opened to traffic. In May 1915, by the terms of a new treaty concluded by China as the result of the Japanese ultimatum accompanying the "twenty-one demands," the lease of the South Manchurian Railway and of the Antung Mukden line was extended to 99 years (*i.e.*, to 2002 and 2007 respectively). By the same treaty Japanese subjects became entitled to lease land for trade, manufacturing and agricultural purposes, and to reside and travel freely in South Manchuria. By notes exchanged as the result of the same "twenty-one demands" China was to permit Japanese subjects to open more mines in South Manchuria. No foreign loans were to be made for the construction of railways in South Manchuria and Eastern Inner Mongolia without the preference being given to Japanese capitalists; preference was to be given Japanese in employing foreign advisers in South Manchuria; and other promises were made favouring the Japanese. In 1917 the whole of the railway system of Korea was linked up with the South Manchurian Railway and placed under its administration. Under these conditions the activities and influence of the railway rapidly became dominant factors in the economic life of Manchuria. In 1916 Japan and Russia agreed by treaty to support each other's rights and interests in the Far East.

In Dec. 1915 a loan agreement was signed between the Chinese and Japanese Govts. for the construction of a railway from Ssupingkai (120 m. north of Mukden) to Chengchiatun; this line was completed in Dec. 1917. In Oct. 1917 a revision of the Changchun-Kirin loan agreement was concluded between the Chinese Govt. and the South Manchurian Railway Company, the result being a loan of 6,500,000 yen for a term of 30 years, during which period the management of the line is vested in the South Manchurian Railway, on behalf of the Chinese Government. In 1918 there were agreements with Japanese interests for the development of mines and forestry and for the construction of four railways.

Russo-Japanese Rivalry.—The disorganisation of the central Government in China and the collapse of Russia after 1917 served to increase the economic, financial and political ascendancy of Japan in Manchuria. For example, after China's entrance into the World War, some of the loans made to Japanese by the Peking Govt. had as security properties and resources in Manchuria. As a result, however, of the negotiations initiated by the United States in July 1918 for the establishment of a four-Power consortium to co-operate in Chinese finance, and of the subsequent *pourparlers* between the British and Japanese Govts. on the same subject, the latter finally agreed (May 1920)—with some important reservations—to withdraw the claims, previously put forward by the Japanese bankers, to exclude from the scope of the Consortium "all the rights and options held by Japan in the regions of Manchuria and Mongolia where Japan has special interests." Japan's power in South Manchuria, however, continues to grow, but at the same time the Chinese have by no means given up control, for they continue to form the great majority of the population, and the provincial organisation and administration are actively maintained. The dominant Chinese figure in Manchuria has increasingly been Chang Tso-lin. General Chang, in 1924 still in middle life, had once been connected with a band of Hunghutze, or bandits, but he had been taken into the service of the Chinese Govt. and in 1911 he was military Governor of Fengtien. From then on, his power grew until by 1920 he was one of the major figures in the Chinese political situation, and Manchuria had become virtually a semi-independent principality under his control. Russian influence, moreover, did not disappear with the collapse of the old régime. For a time it was weakened, but with the establishment of regular diplomatic relations between the Soviet Govt. and China in 1924, Russian power, while by no means fully restored, was again increasing.

Despite an agitation in Japan, the Japanese Govt. has maintained its policy of strict neutrality in the civil war—a policy reiterated by Baron Shidehara, the Japanese Minister for Foreign Affairs, in the Diet in Jan. 1926. Some alarm seems to have been aroused in Moscow by a contract given in April or May of 1925 by Chang Tso-lin to the South Manchurian Railway Company for the construction of a line from Taonanfu in Inner Mongolia to Tsitsihar in northwest Manchuria on the ground that it invades the old Russian sphere of influence in North Manchuria. Rapid progress was made by the Japanese with this railway which was expected to be open for traffic as far as the Nonni river by Aug. 1926. The Soviet authorities are also reported to have protested against the strengthening of the Japanese forces in North Manchuria in 1925 as a violation of the spirit of the Japanese-Soviet Treaty of 1924. (*See* CHINA; CHINESE EASTERN RAILWAY.)

Trade Statistics.—The economic progress achieved in Manchuria had been very rapid since 1912. This might have been expected in regions with vast undeveloped resources and with an increasing, industrious population. Much of the expansion of its trade and industries must also be ascribed to the enterprise shown by the Japanese in the development of mines, forestry and agriculture, and in improving transport, communications and currency.

Figures show the rapid increase of South Manchuria's trade and reflect the effects of the Russian débâcle upon the commerce of the northern province. In 1916 the maritime customs receipts in the northern provinces were 21 % of the total for Manchuria. In 1920 they were 12 % of the total, and in 1922 17 per cent. In 1919 the total direct foreign trade of Manchuria was taels (Hongkong) 299,523,736 and in 1922 it was 285,861,094. Dairen (Dalny) now ranks second only to Shanghai in the list of China's maritime ports. In 1922, 56·5 % of Manchuria's direct foreign trade passed through Dairen (Dalny). In 1908 the trade of Manchuria represented 11·5 % of China's total; in 1918 the proportion had risen to 16·8 %; in 1922 it was 17·5 per cent. Naturally the bulk of South Manchuria's foreign trade was with Japan. The anarchical conditions prevailing in Russia and Siberia after 1917 served to increase Japan's economic and financial influence in Northern Manchuria, the rouble note being replaced in many parts of the country by the yen notes of the Bank of Chosen, which in Jan. 1918 was given control of the treasury business of the Japanese Govt. in Manchuria. At the end of 1918 this bank had 18 branches operating in Manchuria (as against 10 in Korea), and notes in circulation to the amount of 30,000,000 yen. According to the statistics compiled by the South Manchurian Railway, the population of Manchuria in 1916 was 20,112,100. The post office estimate for 1922 was 22,083,434. (*See* CHINA.)

(K. S. L.)

MANDATE.—The mandate system is a term applied to the conditions set up by the Treaty of Versailles for the administration of the former overseas possessions of Germany and Turkey. Mandatory Powers are those Powers which were selected by the Supreme Council of the Allies to administer these territories under mandate. The system is a novel experiment in the relations between a sovereign State and a country under its control, involving new departures in international law. It was created by Art. 22 of the Covenant of the League of Nations, which formed part of the Treaty of Versailles, and has thus gained the recognition of all States that are members of the League.

In its origin it was in the nature of a compromise. After the War the victorious Allies naturally wished to retain the German and Turkish colonies, in the conquest of which they had in most cases made great sacrifices. It was believed that these colonies had been subjected to misrule; pledges had been made to the native inhabitants, some of whom had taken part with the victors in the fighting, that they should not be handed over to the vengeance of their former masters; and finally, a misgiving existed lest, in case of rendition, Germany might use them as recruiting grounds for black armies, and their ports as bases for submarines in a future war. On the other hand the Allies had declared—more particularly in the pre-Armistice statement of Nov. 5 1918—that annexation of territory was not their aim in the War.

International control of some kind was the only alternative. Joint administration was condemned as impracticable and opposed to the interests of the people. Even as a condominium between two Powers only, it had given rise to friction in Egypt, Samoa and the New Hebrides. The only other course lay in the appointment of an individual Power in whom could be vested responsibility for the administration of each separate territory as an agent, or mandatory, of the League. For this course there were analogies in the delegation of quasi-sovereign powers to British and Dutch chartered companies and in the control of the Ionian Is. on behalf of the Powers by Great Britain in 1859. Individuals also had been appointed as mandatories of the Powers, as when King Leopold undertook control of the "International Free State of the Congo," or when Prince George of Greece was made Governor of Crete in 1898.

The main defect of these delegations of sovereignty was that they provided no machinery to ensure the due execution of the trust, and it is the distinctive feature of the mandate system that it attempts to remedy this defect. The League of Nations afforded just such a supervisory authority as was needed, and its supervision is exercised through the medium of a standing committee, known as the "Permanent Mandates Commission." The League had nothing to do with the assignment of the mandates or with their terms, or with the extent and boundaries of the territories. These were determined by the Supreme Council. The United States, not being a member of the League, was no party to this arrangement, and she insisted that as an Associated Power her consent was necessary. The mandates therefore were submitted to her, and approved on condition that "free and equal treatment in law and in fact was secured to the commerce of all nations." Where the mandate did not ensure this she negotiated separate treaties with the mandatory concerned.

Terms of the Mandates

The mandates were formed to give expression in detail to the principles embodied in Art. 22 of the Covenant (*q.v.*), and since that article prescribes that their character must vary with the varying conditions of each territory they were divided into three classes to correspond with the three paragraphs of that article.

Class A includes the former Turkish vilayets of 'Iraq, Palestine and Syria whose independence "can be provisionally recognised, subject to the rendering of administrative advice and assistance until they are able to stand alone." The two former were assigned to Great Britain, the latter to France.

Class B comprises the ex-German Central African colonies—Togoland, Cameroons, Tanganyika and Ruanda—in which the mandatory is responsible for the administration and undertakes to promote the moral and material welfare of the people. Tanganyika, and a small part of the Cameroons and Togo fell to Great Britain, the major portions of the two latter being assigned to France, while Belgium became responsible for Ruanda.

Class C territories include those which "can best be administered under the laws of the mandatory as integral portions of its territories, subject to the safeguards in the interests of the indigenous population" which are laid down for Class B. They are South-West Africa, Samoa, New Guinea, the islands north of the equator in the West Pacific and the tiny island of Nauru. For these respectively the Union of South Africa, New Zealand, Australia, Japan and the British Empire accepted mandates.

In the case of Nauru, Great Britain, Australia and New Zealand had by agreement in July 1919 (before the issue of the mandate), jointly acquired control of the phosphate deposits, which constitute the sole value of the island, and they jointly undertook the execution of the mandate. Since, however, the British Empire has no single code of laws, the administration was assigned by the two others to Australia for five years.

The "safeguards in the interests of the indigenous population" to which reference is made are: (1) freedom of conscience and religion, subject only to the maintenance of public order and morals; (2) prohibition of abuses such as the arms and liquor traffic and the slave-trade; and (3) prevention of fortifications, naval and military bases, and the military training of natives except for police and the defence of the territory.

The mandates were conferred by the Supreme Council of the Allies, and after acceptance by each mandatory were submitted to the Council of the League, which was charged with the duty of seeing that their terms were in accord with the Covenant. They were finally approved by the United States. The A class could not be issued until the Treaty of Lausanne came into force (Aug. 1924). Meanwhile an Arab government had been set up in 'Iraq, and a treaty had been concluded by Great Britain with it. On Sept. 27 1925 the Council formally accepted the undertaking of the mandatory to see that the terms of this treaty (which embodied the obligations of the Covenant) were adhered to, and this undertaking was substituted for the mandate. These long delays were very prejudicial to the welfare of the people of Asia Minor. The territories were, however, administered in accordance with the terms of the Covenant or under draft mandates. These terms are explicit. The mandate is a "sacred trust of civilisation" to be assumed by nations who (*inter alia*) "by reason of their resources can best undertake this responsibility and are willing to accept it." The altruistic nature of this pledge was confirmed in a reply to a German protest. "The Mandatory Powers," said the Allies, "in so far as they may be appointed trustees by the League of Nations, will derive no benefit from such trusteeship."

A mandated territory differs from a protectorate in that the protecting Power in the latter obtains rights over the population and against other Powers, whereas a mandatory in its capacity as guardian assumes obligations both toward the population and the League. These thus acquire rights as against the mandatory.

League Control.—The system, it has been said, differs from such partial precedents as have been cited, in that it attempts to set up machinery by which the proper execution of the mandate may be assured. This consists in the unqualified right of supervision vested in the League which imposes upon each mandatory the obligation to submit an annual report on its administration.

The Permanent Mandates Commission examines these reports in the presence of an accredited representative. The commission consists of nine members of the following nationalities: Belgian, British, Dutch, French, Italian, Japanese, Portuguese, Spanish and Swedish—to which has recently been added an "additional member" (Swiss). The majority are nationals of non-mandatory states. They are selected "for personal merit and competence" as private individuals, and not as representatives of their respective nations. They are nominated by their governments, but approved and appointed by the Council of the League, and may not hold any office under their government. A representative of the International Labour Office attends the sessions, and takes part in any discussions relative to labour. This international composition negatives any suspicion of bias, and gives to the commission the aspect of an impartial tribunal of practical men, whose object it is to promote co-operation while fearlessly exposing any breach of the Covenant. Its functions are purely advisory to the Council.

A permanent secretariat, under a director, collects and circulates all documents of interest concerning mandates and conducts the routine business. The duties of the commission are not confined to the annual review of the reports of the mandatories. It receives any petitions and memorials from inhabitants of the territories and others interested, and these, unless trivial or irrelevant, are forwarded to the mandatory concerned before examination by the commission, which also makes a special study of questions arising either in relation to the system or to the various problems of administration. Notes for guidance in preparing their reports are circulated to mandatories, dealing with such matters as slavery, labour, traffic in arms, liquor and drugs, liberty of conscience, the judicial system, military forces, economic equality, education, public health, land tenure, public finance and matters relating to general administration and the moral and material welfare of the people. The proceedings are conducted in French and English, and are generally held in private to facilitate freedom of discussion. Full minutes are printed, which, together with the memoranda on special subjects and all other pertinent papers, can be obtained from the League publication department, or from its agents in London and other European capitals. The Commission meets at least twice in the year at Geneva, and its procedure is governed by rules approved by the council.

The weak point in the system lies in the impossibility of independent verification of statements contained in the reports. This difficulty is inherent in the circumstances, for it would clearly be impossible either for the whole commission or any part of it to visit a mandated territory officially, and to sit in judgment on the policy of a Sovereign Power. Even an official visit for the purpose of acquiring information would be of doubtful wisdom, as tending to weaken the prestige of the mandatory and to afford opportunity for malcontents to manufacture grievances. For information not contained in the report, therefore, the commission must rely on those public bodies or individuals who interest themselves in the welfare of native races, and on such memorials and petitions as may be presented to it.

The sole means at its disposal—or at the disposal of the League—for compelling the proper execution of the mandate is the force of public opinion, though in case of deliberate violation of the mandate and of gross maladministration, the council could no doubt send a commission of enquiry, and in theory the legal possibility of revocation for failure on the part of the mandatory to fulfil its contract no doubt exists. In order to obtain more accurate information, the actual administrators now generally appear as the mandatory's representatives. Steps are also being taken to secure a wider distribution of the sessional papers of the commission, with a view to enlarging the orbit of well-informed public opinion and perhaps of exerting an influence on the standards of colonial administration.

Interpretation of Article 22.—The creation of the mandates system—though a task of enormous importance, involving issues new to international law and affecting the destinies of many millions of the human race and of property in every quarter of the globe worth many hundreds of millions sterling, was only one of the many preoccupations of the Versailles Conference. Owing to the circumstances of the moment many matters of less permanent and historic importance claimed an undue attention. Critical examination and practical experience have therefore detected many points which require elucidation or authoritative interpretation. In some particulars, for instance, the mandates do not strictly conform to the terms of Article 22. In the A mandates the treaty enjoins that "the wishes of the communities must be a principal consideration in the selection of the mandatory," and it is common knowledge that the communities concerned were never consulted. The paragraphs in Art. 22 on which the B and C mandates were framed do not contain any similar injunction, though explicit statements to the same effect had been made.

Military Service.—Again, the French mandates in West Africa —unlike the British mandates for portions of the same territories (Cameroons and Togo)—contain a clause to the effect that "troops thus raised" (*i.e.*, for purposes of local defence and police) "may in the event of general war be utilised to repel an attack, or for defence of the territory outside that subject to the mandate." It is difficult to reconcile this clause with the words of the Covenant. At the instance of the Mandates Commission the British Govt. was willing to go even further than the Covenant prescribes, and to agree to pledge itself not to enlist the natives of a mandated territory, even though they offered themselves for enlistment outside its frontiers—thus limiting its sovereign rights in adjacent territories not under mandate. The French Govt. has declared its willingness to accept the same restriction.

The original intention of the treaty would seem to have been to exclude all mandated territories and their inhabitants from participation in a general war; but the mandates for Palestine and Syria authorise the mandatory "to make use of the ports, railways and roads for the passage of its troops and of all materials, supplies and fuel," and local forces may be used for purposes other than defence. These countries thus automatically became involved in any war in which the mandatory may be engaged. It is not clear what is the position of the C mandates in this regard.

Liquor Traffic.—The Covenant enjoins the "prohibition of abuses such as the slave-trade, the arms traffic and the liquor traffic." Some have urged that these words mean the enforcement of total prohibition alike for natives and non-natives. The mandates, however, only prescribe a "strict *control* over the sale of spirituous liquors," and the St. Germain Convention (Sept. 1919), concluded soon after the Versailles Treaty by the same signatories, forbids the import of "trade spirits" only. Relying on these facts, others contend that the term "liquor traffic" is used in the Covenant in the technical sense in which it is usually employed in West Africa, and means the "importation of cheap, distilled liquors for sale or barter as an article of trade with the natives." The Mandates Commission has consequently asked the council for an authoritative definition of this and other ambiguous terms used in the Covenant.

In the matter of equal commercial opportunity for all nations, the Covenant itself failed to fulfil the expectations raised by the pre-Armistice declarations of the Allies. No obligation in this regard is imposed in the C mandates, while in the B class it is restricted to States which are members of the League.

Legal System.—The essential distinction between the B and C classes of mandates, in the terms of Art. 22, lay in the dictum that the latter "can best be administered under the laws of the mandatory, as integral portions of its territory," but the British and French mandates for Cameroons and Togo, and the Belgian mandate for Ruanda (all of the B class) contain a clause in identical terms.

Boundaries.—Yet another cause of practical difficulty is presented by the fact that in many cases the boundaries of the territories assigned under mandate were not defined, and it was apparently left to the individual mandatories to adjust them without reference to the League. In the case of 'Iraq this has led to an acute dispute with Turkey. In Palestine the boundaries of Trans-Jordania are still undefined. In Northern Syria the French, having, as it was understood, agreed to accept a mandate for Cilicia, abandoned it to Turkey without apparently any authority from the League to do so, and the frontiers are still indeterminate. So again in Ruanda, where an adjustment, involving the cession of a considerable area by Great Britain to Belgium, was effected and approved by the League. On the northern frontier of South-West Africa negotiations are in progress between the Union Govt. and the Portuguese.

Sovereignty.—Wider issues are raised by such questions as the nature and extent of sovereignty exercised by a mandatory and the international status of the inhabitants of a mandated territory. The former—which has been much debated by American publicists—is rather academic and juridical than of practical interest. It suffices for practical purposes that the mandatory has the absolute right to make and enforce laws, to raise troops, to set up tribunals, to appoint officials and to raise and spend revenues. Sovereignty was not ceded by the Treaty of Versailles to the League, but to the victorious Allies—indeed the highest court in South Africa has recorded the opinion that the territories were not ceded at all, but placed by Germany at the disposal of the Allies, to be administered under mandate—a status new to international law.

The mandatory's powers are exercised "in its capacity as such." It has, for instance, been satisfactorily established by the Mandates Commission that such terms as "crown (or state) lands" and *domains d'état*, where they appear in local ordinances, refer only to lands which are the property of the mandatory as such, in other words, to the mandated territory, and that any action on the part of the mandatory which had for its object (or would ultimately involve) annexation—as for instance the acquisition of large monopolistic rights, or of essential public services—would be contrary to the spirit of the Covenant and the mandate.

Status of Natives.—The status of the indigenous inhabitants of a B or C mandate territory has on the other hand been the subject of special definition. Obviously, since the country is not annexed, they do not become the subjects of the mandatory. The formula was therefore adopted by the Council that "they should be designated by some form of descriptive title which will identify them as such," viz., as "persons administered or protected under mandate." This confers no juridical status, and no privilege of citizenship, but Art. 327 of the treaty stipulates that they should be entitled to the diplomatic protection of the mandatory when outside the mandated territory, and individuals may if they so desire become naturalised subjects of the mandatory. Since residents in a British Protectorate cannot acquire British nationality, and since a person "protected under mandate" could not be placed in a more favourable position in such a matter than a resident in a British Protectorate it was decided at an Imperial Conference that the power of granting certificates of imperial naturalisation should be extended to persons resident in certain named protectorates, and in mandated territories. Extradition treaties with France have similarly been extended, the natives being regarded for this purpose as "assimilated" to those of a colony.

The application to mandated territories of special conventions, entered into by a mandatory Power, has also been the subject of investigation and recommendation by the Mandates Commission, in order to ensure that "persons protected under mandate" shall not be in a less favourable position in regard to their persons and property and their economic interests than the inhabitants of a protectorate or colony.

Permanence of Mandates.—The revocation of a mandate for maladministration, though theoretically possible, is in practice unthinkable. Voluntary transfer or abandonment (with the sanction of the League) is hardly more conceivable. The terms of the Covenant therefore contemplate self-government as the natural fruition of the mandate—in the case of the A class at no distant date. The new state—as is proposed in the case of 'Iraq—would then take its place as a member of the League, or perhaps, as in the case of South-West Africa, would be federated with the mandatory.

Conclusion.—The mandate system enforces, for the first time in history, the principle of trusteeship, and of public responsibility to a supervising authority for the obligations laid down in the trust deed in regard to mandated territories. The annual report forms an effective means of inviting a popular verdict on the fulfilment of the trust, and this supervision constitutes a fundamental distinction from annexation, whatever the degree of assimilation to other possessions of the mandatory. The League exercises supervision but not control, for the ultimate authority to which the stewardship of the mandatory is submitted is the public opinion of the civilised world. The standards of the Covenant must obviously in the future be regarded as principles of general application. The mandate system is an international acknowledgment of the responsibility which the advantages of a superior intellectual culture and twenty centuries of Christian ethics no less than the physical superiority conferred by the monopoly of firearms impose upon those Powers which have accepted control of backward races. *See* LEAGUE OF NATIONS.

MANGANESE (*see* 17.569).—The principal use of manganese is in the manufacture of iron and steel, about 95% of the world's production of manganese ores, manganiferous iron-ores, and manganiferous zinc residuum being consumed in metallurgical processes. Its chief chemical uses are as a constituent of oxidising agents and colouring materials, and as a flux in the smelting of silver and lead ores. Salts of manganese are used as fertilisers and massive rhodonite as an ornamental stone. Manganese is also used for medical purposes. Ores of the metal are widely distributed, but deposits of commercial importance are known only in a few countries. The principal of these are Russia (Caucasus), the ore of which consists mainly of pyrolusite; India, Brazil and West Africa. Minor producers of the metal are Italy, Spain, the United States, Cuba and Japan; while deposits are also known in Germany, Greece, Egypt, Canada, Mexico, Colombia, Chile and Queensland.

For many years before the World War, Russia was the main producer, the figures for 1913 being 1,234,900 tons. The Russian industry suffered severely during and after the War, however, and the export figures in 1923 had fallen to 407,401 tons. These figures, however, represent a considerable advance on those of the years immediately preceding. The circumstances which acted so detrimentally to Russia imparted great impetus to the Brazilian manganese industry, the United States absorbing practically the whole of the much increased output of the South American States. In 1916 the United States obtained 80%, and in 1917 83%, of its manganese ore from Brazil. In the Morro de Mina mine, in the state of Minas Geraes, Brazil has what is probably the largest manganese mine in the world.

Production in India began in 1892, in the Madras Presidency, but in 1899 rich deposits were discovered in Central India and from this date the industry in India assumed importance. The India ore is more suitable for blast furnaces than the softer ores of the Caucasus, and, owing to more careful selection, is exported in more uniform quality. Its main constituent is psilomelane, with an important amount of braunite.

In the Gold Coast, West Africa, large deposits of manganese were discovered at Dagwin, near Taquah. Work was commenced here in 1916, and the first shipment of 174 tons made in the same year. In 1923 the production had risen to 139,634 tons. The Dagwin mineral generally is psilomelane, though pyrolusite is occasionally found. The average percentage of manganese plus iron is 55–56.

Production of Manganese by Principal Leading Countries.
Quantity (long tons)

Country	1913	1918	1923
India	815,047	517,953	695,055
Gold Coast	..	30,292[1]	139,634[1]
Russia and Georgia	1,234,900	150,000[2]	407,401
Italy	1,596	31,383	9,451
Austria	16,280	177	23,647
Brazil	120,335	387,066	232,041
Spain	21,247	76,465	28,175
United States	4,048	305,869	31,500[1]
Japan	17,755	56.109	4,926

MANGIN, CHARLES EMMANUEL (1866–1925), French soldier, as born at Sarrebourg, Moselle, July 6 1866 of a military amily, his father having been a general of division. ne of his brothers was killed on active service at Tongking; hile another, formerly a White Father but during the War a ergeant in the Senegalese Tirailleurs, died in the North African esert a few months after the Armistice. Mangin, himself, was ot unworthy of his family history. He left the École Spéciale ilitaire at Saint Cyr in 1888 for Africa, and with the exception f three years spent in Tongking, and 10 months in France, he emained for 26 years in different parts of Africa. In 1891 he ecame a lieutenant, in Nov. 1897 a captain, in Jan. 1900 the ommander of a battalion, in Dec. 1905 lieutenant-colonel, nd later, colonel. In Aug. 1913 he was promoted to the rank of eneral of brigade. His travels in Africa were extensive; he isited Dahomey, Senegal, the Sudan, the Congo, Morocco and ake Chad. He was a member of Marchand's expedition and vas one of the legendary company who were said to have narched "for three days without a halt." It was he who, at the ead of 5,000 men, routed the bandit El'hiba and all his followers n the plain of Ben Guerir and so relieved Marrakesh. His coniderable literary abilities, which he had rarely the leisure to xercise, were also devoted to Africa; and his book, *La Force oire* (1910) brought home to Frenchmen the immeasurable esources of their empire.

When the World War broke out General Mangin was 48 years f age. At first in command of the 8th Brigade and, after April 1916, of the 5th Infantry Division, he threw the enemy back pon Douaumont, which he reached on May 22. Five months ater, on Oct. 24, he hurled two divisions against the Germans and ook Douaumont and Vaux. In 1917 he was in command of the . Army, and in the following year at the time of the April ffensive the Supreme Command imposed upon him the hard ask of checking the German offensive directed against Comiègne. Eight fresh divisions were entrusted to him, and with hese 60,000 men he checked von Hutter's advance at Noyon. ubsequently he was entrusted with the X. Army and was rdered, in conjunction with General Degoutte, to break in the erman salient south of the Aisne. This he accomplished; the hemin-des-Dames, the Château de Coucy and Laon were uccessfully re-occupied. At the time of the Armistice, he would ave been the first to enter Metz at the head of his troops, in ompany with Marshal Pétain, had not an unfortunate accident t the last moment prevented this. For a year he commanded the rmy of Occupation on the Rhine. In June 1921 he was sent as mbassador Extraordinary to represent France at the celebrations f the centenary of Peruvian independence.

General Mangin held the Grand Cross of the Legion of onour, was a member of the Supreme War Council, was nspector General of the Colonial Forces, and presided over the upreme Council for National Defence. But his life work was to evelop to the maximum his country's African resources. He ied on May 12 1925, and was buried with military honours in he Montparnasse Cemetery. Above his head stands a simple tone bearing this inscription: "Ici repose un soldat français." (M. Gu.)

MANIPULATIVE SURGERY.—The earliest practitioners of bone-setting"—the old misnomer for what is now more corectly described as manipulative surgery—date back into very emote times, and Hippocrates, although not versed in a knowldge of structural anatomy, was the author of a treatise on disocations which will bear comparison with many presentlay publications on the subject. The history of the Roman epublic tells of successful practitioners of this ancient craft.

During the years when surgery was gradually being regularised and its seats of learning were being established, "bone-setters" were the only orthopaedic surgeons of those days, and the doctors apparently countenanced them as legitimate exponents of that section of therapeutics. The famous surgeon, William Cheselden, in the middle of the 18th century, who was a warden of "The Master Governors and Commonalty of the Art and Science of Surgeons of London" used to send cases to the bone-setters for treatment, and frankly admitted that he did so because he was not competent to treat them himself.

Hunter's Attitude.—The renowned surgeon, John Hunter, with great foresight and acumen, was amongst the first of eminent surgeons to realise the value of early movements in cases of sprains and joint injuries. He wrote: "Nothing can promote contraction of a joint as much as motion before the disease is removed, but when all inflammation is gone off . . . a little motion and frequently repeated is necessary to prevent healing taking place with the parts fixed in one position."

Paget's Advice.—The world of conservative surgery owes an unpayable debt of gratitude to Sir James Paget who, in his desire for the public weal and the true interests of science, wrote to *The British Medical Journal* in January 1867, urging his professional brethren to "learn what was good in the methods of the bone-setter, and eschew what was harmful." Paget stood on firm ground and spoke with unshakable certitude when he declared that "too long rest is by far the most frequent cause of delayed recovery after the injuries of joints, and not only to injured joints but to those that are kept at rest because parts near them have been injured." But notwithstanding the high position in the profession of this far-seeing practitioner, his exhortations passed almost unheeded and the tradition of rest persisted in spite of its frequently disastrous results.

Later, Dr. Wharton Hood, who had conceived the greatest admiration and respect for Robert Hutton, the bone-setter, and who recognised the false teaching of his profession in regard to many forms of joint injuries and derangements, made a thorough investigation of Hutton's methods, and after the bone-setter's death published a description of them in *The Lancet.* But Wharton Hood's motives were wrongly interpreted. He was accused of associating with a "quack," and prejudice once more dealt a heavy blow at the progress of science. But happily, the seed thus sown is to-day beginning to result in a harvest of delayed therapeutic methods which are of the greatest usefulness to crippled humanity, and the early pioneers who were so bitterly assailed and persecuted will find in posterity their full reward.

Types of Cases.—Flat-foot, with its distressing deformity and painful crippling of the patient, occupies a front place amongst those cases which yield most satisfactorily to skilled manipulative treatment. To commence to correct this abnormality in its early stages is important, though cases might be instanced of patients, even up to 60 years of age, making perfect recoveries. The time of puberty is the period at which the irregularity usually makes its appearance, and the progress of the trouble is usually rapid and the deformation very marked.

It is difficult to assign with certainty the predisposing factor in such cases, though heredity probably plays some part in its origin. As many as four members of one family have been known to suffer from the complaint. The hands of the operator—if sufficiently powerful—constitute a much more effective instrument for forcing the foot and ankle into their normal positions than the Thomas wrench which is largely used even now. Several corrections should be made at short intervals, followed immediately by certain exercises in place of the one or two adjustments which used to be considered sufficient. The encasement of the joint in plaster of Paris is secure immobilisation and rest in bed must on no account be recommended. The anatomical contour of the foot is palpably bettered even after the first manipulation, and each operation brings the patient nearer full recovery. Almost all cases of adhesive and acquired flat-foot should recover. Congenital cases are much less satisfactory, though even in these improvement can generally be looked for. The technique is difficult and should be taught by cinematographic pictures so slowly reproduced that students can follow each manipulation carefully.

The Shoulder Joint.—The habitual derangement of the shoulder joint—sometimes on the slightest provocation, such as sneezing, stretching or ordinary reaching—is a most troublesome affection and is usually attributed to a rent or tear in the capsule, brought about in the first instance by a severe wrench, although cases could be recorded where no history of accident can be remembered. The disability is probably more often caused by adhesive contracture of a section of the capsule with an accompanying exaggerated relaxation of the remaining portion which allows the dislocation to take place. Although surgeons frequently advise a surgical operation, certain manipulations bring about a condition of the capsule which will enable it to exercise normal control of the head of the bone followed by exercises designed to re-establish the surrounding weakened tissues. Out of a number of cases only 2 or 3 can be remembered as not having yielded satisfactorily to treatment—even after a repetition of the operation. The procedure, under an anaesthetic, is quite devoid of danger, and the after-effects are of brief duration and only slightly painful.

Subluxations and Dislocations.—The actual reductions of gross dislocations do not enter to any great extent into the purlieu of the manipulative surgeon. There is, however, a large number of conditions due to minor displacements which constitute an important branch of his work. Principal among these must be placed displacements and fracture-displacements of the semilunar cartilages of the knee-joint. This field is an enormous and most important one, for the number of persons of both sexes who sustain such injuries is legion. In original unreduced displacements, reduction must be carried out by appropriate manipulation at the earliest possible moment. In chronic or recurrent cases, manipulation is also very frequently effective in bringing about a cure of a very troublesome and disabling condition.

The brilliant results obtained in this type of case have been known for many years, but the underlying pathology has been a profound puzzle until it was recently shown:

(a) that by far the commonest type of injury of the internal semilunar cartilage is the complete longitudinal tear;

(b) that in this type of case, the outer portion of cartilage is nearly always found in the interior of the joint;

(c) that by appropriate manipulative technique this displaced fragment may be made to retrace its steps and come into apposition with the inner fragment;

(d) that when this has been effected, there is a good chance of repair occurring between the two fragments.

Cases with Adhesions.—These constitute another important class. It is essential first of all to make quite clear what we mean by the term " adhesion." It is probably known to most that an inflammatory process is usually accompanied by the exudation of lymph from the blood-vessels of the part. This lymph tends after a short while to become organised, *i.e.*, changed into connective tissue, or, as it is usually called, " fibrous tissue." Let us imagine, for example, that owing to a severe sprain of the knee the lining membrane of the joint has become inflamed. As a result there is an outpouring of this lymph by the blood-vessels of the membrane, and various folds and layers of this selfsame membrane tend to become adherent by this inflammatory exudate. When this has become converted into fibrous tissue, adhesions are actually present which may give rise to marked disability. It is characteristic of adhesions that, when pulled upon or stretched, severe pain usually results. Further adhesions give rise to a variable amount of limitation of some particular movement or movements of the joint, which is apt to be overlooked unless a most careful examination be made.

Swelling of the joint after exercise, muscular wasting, and a sensation of weakness and often an actual giving-way of the joint, are not infrequent characteristics of adhesions.

Danger of Rest for Joint Cases.—As previously stressed, the doctrine " rest inflamed structures " has been responsible for the formation of countless thousands of joints disabled by adhesions. However true the doctrine may be in certain other organs and structures of the body, and even this is debatable, in the case of a joint it is dangerous, for the function of a joint is movement and movement must always be instituted at the earliest possible moment in almost any inflammatory condition, except in those ultra-acute conditions where movement is impossible and in some cases of tubercular disease and of myositis ossificans. When a joint has become crippled owing to the presence of adhesions, how is the joint to be restored to its pristine health and vigour? The answer is manipulation.

It is obviously impossible, in a short article of this nature, to detail the various technical methods of manipulation that apply to the different joints. Anaesthesia, although not absolutely essential, is a valuable aid in many cases, owing to the complete muscular relaxation thereby attained. The cases that are attended with the greatest success are those in which the adhesions are slight and in which the subsequent reaction is negligible. In more marked cases much benefit often follows from a series of manipulations separated by short intervals.

Although particular emphasis has been laid on adhesion in connection with joints, it is most important to remember that this may occur in many other important situations, particularly in the vicinity of muscles, or in their sheaths, or between different groups of muscles. This may also occur in connection with tendons and their sheaths, and in fascial or connective-tissue structures.

Functional or Hysterical Cases.—These constitute an interesting and important group in which good results by manipulation are sometimes attained. It must be remembered that a functional case is primarily mental and this condition is particularly apt to occur after injury in a person of nervous temperament. Although there is no actual organic disease of the joint—at any rate in the early stages—yet it is extraordinary how a functiona condition of a joint may simulate some organic disability of the same joint. Great experience and clinical acumen are often required to form a correct diagnosis of such types.

The great value of manipulation in these cases is that a vicious circle is thereby broken, and, although an anaesthetic is not absolutely essential, yet, if some such anaesthetic as ga or gas and oxygen be given, it has a powerful suggestive effec upon the patient. It is usually found that, as soon as the patien is under the influence of the anaesthetic, the joint, which previously was held awkwardly and stiffly, becomes relaxed. Th surgeon places the joint in the position which was erstwhile impossible and retains it thus until the patient is fully conscious The patient is then shown the increased mobility and encourage immediately to move the joint through this increased range Much subsequently depends upon the patient being surrounde by an atmosphere of cheerfulness and encouragement, an everyone with whom the patient comes in contact must endeavour to play his or her part in the cure and to assure the patien of its completeness and finality. A great responsibility thus devolves upon friends and relations that the good work of th manipulator may not be subsequently jeopardised by misplace sympathy or injudicious advice.

It must be borne in mind that in cases of long standing, actua organic changes may occur in an hysterical contracture, and the contracture, which was previously due to muscular sprain, becomes fixed by scar tissue. It is therefore important that manipulation should not be delayed too long in these cases, especially as the mental state becomes more fixed and more difficult t treat with the passage of years.

Cases Relieved by Manipulation.—This large group includes a great many conditions due to disease rather than injury, the principal probably being the group of infections and intoxications usually known by the name " rheumatic," especially in its mor chronic forms. Here again it is obvious that those cases in which only a slight degree of stiffness of a joint is present are muc more satisfactory from the point of view of treatment tha cases of marked stiffness or cases in which well-marked destruction of the joint surfaces has occurred. It is important also to wait until all signs of activity have subsided and furthermore to eradicate the cause wherever possible before having recourse to manipulative measures. In nearly all cases of strains and sprains entle manipulation at the earliest moment is recommended be-use the reparative processes of nature act most effectually hen, as far as possible, no interference whatever with their unctions is resorted to. (H. B.*)

MANITOBA (*see* 17.584), a province of the Dominion of anada. By an Act of the Canadian Parliament passed in e session of 1911–2 the eastern boundary of Manitoba was xtended north to lat. 60° N. and northeast to the point where e meridian of 89° W. intersects the southern shore of Hud- on Bay. This gave the province possession of two ports n Hudson Bay—Fort Churchill and Port Nelson. The effect f the change was to increase the area of Manitoba to 251,832 q. m., of which about 13,500 sq. m. are covered by lakes. The opulation of Manitoba in 1921 was 610,118 an increase of 2·23 % over 1911. The rural population was 348,502 and the rban 261,616. The legislative assembly consists of 55 members ith an executive council of the premier and six members. The rovince is represented in the Dominion Parliament by 17 mem-ers of the House of Commons and six senators. There is an xcellent secondary and public school system. Higher education provided by the University of Manitoba which has affiliated ith it several church colleges and professional schools. The lanitoba Agricultural College, near Winnipeg, is supported by e province.

Production and Industry.—The following table shows the otal yield in bushels of the principal field crops for 1910, the nnual average 1922–4, and 1925:—

Crop	1910	Av. 1922–4	1925
Wheat	34,125,949	45,773,000	39,453,000
Oats	30,378,379	67,955,333	71,770,000
Barley	6,506,634	31,837,333	52,156,000
Rye	29,205	5,857,667	5,152,000
Flax	176,675	1,844,000	1,664,000

In 1925 the number of live stock amounted to: horses, 359,839 ttle, 720,745; sheep, 101,997; and swine, 298,507. Dairying ecame firmly established after 1915, and both production and port greatly increased. In 1924 the chief dairy products were reamery butter, 12,632,804 lb.; dairy butter, 9,285,464 lb.; heese, 500,633 lb.; and milk over 200,000,000 gallons. Large uantities of fish are obtained from Lakes Winnipeg and Mani- oba, principally whitefish, sturgeon, pike and pickerel. The nnual value of the fisheries during the post-War period exceeded 1,000,000.

Copper ore occurs in the Pas district. Gold has been found in ntiguous areas. A mottled limestone is quarried at Tyndall, east Winnipeg, and is in wide demand as building stone. Gypsum eposits are mined northeast of Lake Manitoba. Portland cement is anufactured at Winnipeg and Babcock. The average annual pro- uction of minerals from 1919 to 1923 was valued at over $2,500,000. he province possesses extensive water power resources. The avail- ble power at ordinary minimum flow is estimated at about 250,000 horse-power. The turbine installation in 1925 was only 69,325 horse-power. The chief industries are meat-packing and ur milling. In 1922, 768 manufacturing establishments with a pital of $84,662,378 gave employment to 13,789 employees, who ceived $17,891,064 in salaries and wages, and utilised $54,619,248 orth of material in producing goods valued at $94,417,608.

Communications.—Railway mileage increased from 3,221 m. in 910 to 4,521 m. in 1925. The transcontinental lines converge at innipeg. Branches have been constructed linking up these lines ith the area west of Lake Winnipeg and with Hudson Bay. Direct nes south to Minneapolis and St. Paul give connection with the nited States. Great progress was made in the construction of ads after the passing of the Manitoba Good Roads Act in 1914: 191 m. of roads had been authorised and $10,985,497 expended by he Government and municipalities between the passing of the Act nd Aug. 31 1924. (*See* CANADA.) (D. A. Mac. G.)

MANIU, JULIUS (1873–), Rumanian politician, was born t Simlaul Sylvanie (Transylvania). He studied at the uni- ersities of Cluj, Vienna and Budapest, and was for many years rofessor of law at the theological academy in Blaj. At the ge of 26 he joined the National Rumanian party of Transyl- ania. In spite of the bitter opposition of Count Stephen Tisza, Maniu was elected deputy and sat in the Parliament at Budapest from 1906 till 1910. When the World War broke out Maniu was sent to the front and in 1918 was fighting against Italy. When he realised that the collapse of the Central Empire was in sight, he went to Budapest, where a National Rumanian Council was formed, Maniu taking charge of military and foreign affairs. He then went to Vienna and organised the revolt of Hungarian regiments, composed of Rumanians of Transylvania, stationed in Vienna and Prague. On Dec. 1 1918 the Rumanian National Assembly at Alba-Iulia proclaimed the union of Transylvania and the Banat with Rumania and elected Maniu, president of the *Consiliul Dirigent* (local government) which took over administrative control throughout Transylvania. In 1919 Maniu was elected president of the National Rumanian party of Transylvania, which in 1925 coalesced with the Nationalist-Democratic party. Maniu became the chief of this new formation, which took the name of the National Rumanian party.

MANN, THOMAS (1875–), German poet and novelist, was born at Lübeck June 6 1875. At the age of 19 he went to Munich where he was at first employed in a fire insurance company, but wrote novels at the same time. He then abandoned his practical calling and attended lectures at Munich University in literature, history and the history of art. He visited Italy, and was afterwards, for a time, editor of *Simplizissimus*. His chief work, excellent in both style and construction, is the period novel, the plot of which is laid in Lübeck, *Buddenbrooks, Verfall einer Familie* (1903, Eng. trans. 1924). His other books include *Königliche Hoheit* (1915), *Der Zauberberg* (1925), and a number of shorter novels including *Der Tod in Venedig* (1912) and *Tonio Kröger* (1914). He also wrote one drama, *Fiorenza* (1906) and *Betrachtungen einer Unpolitischen* (1918), a declaration of Conservatism. See Fr. Leppmann, *Thomas Mann* (1916).

MANNING, WILLIAM THOMAS (1866–), American Protestant Episcopal divine, was born in Northampton, England, May 12 1866. He graduated at the University of the South, Sewanee, Tenn., and entered the ministry from the diocese of California, being ordained deacon 1889 and priest 1891. He became rector of Trinity Church, Redlands, Cal., 1892, and was appointed professor of theology in the University of the South, 1893. He became successively rector of St. John's, Lansdowne, Pa., 1896; rector of Christ Church, Nashville, Tenn., 1898; Vicar of St. Agnes's Chapel, Trinity Parish, New York City, 1903. In 1904 he was appointed assistant rector of Trinity Church, New York City, becoming rector in 1908. He was consecrated Bishop of New York May 11 1921. A constant advocate of Christian unity, he was prominent in promoting the World Conference on Faith and Order. In 1925 he inaugurated the public movement for the completion of the Cathedral of St. John the Divine, New York City.

MANOEL II., ex-King of Portugal (1889–), was born at Lisbon Nov. 15 1889, the younger son of Carlos I. by his wife Marie Amélie of Orleans. On the assassination of King Carlos and of the Crown Prince Luis, Duke of Braganza, Feb. 1 1908, Dom Manoel succeeded to the throne of Portugal, but he only retained it for a short time, as the revolution of Oct. 3 1910 forced him to flee the country (*see* PORTUGAL). He took refuge with his mother in England, and finally settled at Fulwell Park, Twickenham. On Sept. 4 1913 he married, at Sigmaringen, Princess Augusta Victoria of Hohenzollern, daughter of Prince Wilhelm of Hohenzollern. Dom Manoel supported the Portuguese Royalist risings of 1911 and 1912, and in the latter year met the pretender to the Portuguese throne, Dom Miguel, at Dover in order to concert a common plan of action. On the outbreak of the World War, however, he appealed to all classes of his former subjects to lay aside political feelings and unite against the Central Powers.

MANSFIELD, KATHERINE (1890–1923), British writer, was born at Wellington, New Zealand, the daughter of Sir H. Beauchamp, and spent most of her girlhood in New Zealand. She published *In a German Pension* (1911), and in 1913 married John Middleton Murry, the critic, with whom she had been associated in the publication of a literary review, *Rhythm*. Her brilliant talent for the short story form was displayed in a collection issued as *Bliss* (1920), and her acute critical powers in frequent contributions to *The Athenaeum*, then edited by her husband. This was followed by *The Garden Party* (1922), but a career of great promise, and small but perfect achievement, was cut short by death, after a long illness, at Fontainebleau Jan. 9 1923. Further stories, *The Doves' Nest,* appeared later in that year, also a volume of *Poems*, and in 1924, *Something Childish,* tales and fragments of minor interest.

MANSHIP, PAUL (1885–), American sculptor, was born at St. Paul, Minn., Dec. 25 1885. He studied at the St. Paul Institute of Art, the Pennsylvania Academy of Fine Arts at Philadelphia, and in New York City. In 1909 he went to Rome, having been awarded a scholarship at the American Academy there, and remained abroad three years. On his return to the United States his works quickly attracted attention by their individuality and his figures, exhibiting archaic traits skilfully coupled with intensely modern feeling, placed him in the front rank of American sculptors. In 1914 he was awarded the G. F. Widener Memorial Gold Medal at the Pennsylvania Academy of Fine Arts, obtaining also a gold medal at the San Francisco Exposition, 1915. He devoted himself chiefly to classical subjects, but executed two very striking portraits, " John D. Rockfeller " and " Miss Manship," the latter being a study of his daughter, aged three days, which is in the Metropolitan Museum of Art, New York City. Among his other chief works are the J. P. Morgan memorial in the Metropolitan Museum of Art; the " Infant Hercules " fountain in the courtyard of the American Academy at Rome; " Dancing Girl and Fauns " and " Indian and Prong-Horn Antelope " in the Art institute, Chicago; " Yawning," in the St. Paul Institute; and " Centaurs " and " Little Brother " (statuette) in the Detroit Museum of Art.

MAP (*see* 17.629).—Steady progress was made in all branches of map construction until the outbreak of the World War, when a type of map not hitherto in general use in warlike operations came into demand. With regard to normal topographical maps a useful landmark was the publication in 1908 by the U.S. Geological Survey of a book on *The Interpretation of Topographic Forms.* Three matters stand out as deserving of special attention—the revival and standardisation of the *International Map of the World;* the striking progress made in the few years immediately preceding the War with the mapping of the British Empire; and the great part which maps played, in all armies and in the fighting on all fronts, during the War, but especially on the Western Front. (*See* SURVEYING.)

International Map of the World.—The official title of this international undertaking is *Carte du Monde au Millionième*, and references to it will generally be found under this title. It owes its origin to the initiative of Prof. A. Penck, who put forward the project of a map of the world on a uniform scale at the Geographical Congress held at Berne in 1891. The scale proposed was one-millionth of nature, equivalent to 1 km. to 1 mm., or 15,178 m. to 1 inch. The scheme and the scale were accepted by the congress, and an international, but unofficial, committee was appointed for the purpose of prosecuting the idea. This committee reported to successive Geographical Congresses held in London in 1895, in Berlin in 1899 and in Washington in 1904, but not very much progress was made.

An important step was, however, taken at the Geographical Congress held at Geneva in 1908. At this congress the delegates of the United States made a proposal for the definite standardisation of the map and for the drawing-up of fixed rules to govern its production. The next step in its history is that the geographical section of the British General Staff took up the subject, and a promise was given at the Geneva Congress that, if possible, an official conference should be assembled to deal with the matter. This promise was carried into effect in the following year.

In Nov. 1909 an official conference assembled at the Foreign Office in London, on the invitation of the British Government. The countries represented were, in addition to Great Britain, Australia, Austria, Austria-Hungary, Hungary, Canada, France, Germany, Italy, Spain, Russia, the United States, *i.e.*, the British Empire and the other European and American Great Powers. The conference came to unanimous conclusions, and an account of it was published in a report issued by the British Government. The object of having an official, rather than a non-official or academic, conference was that experience had shown that without the support of the official map-making bodies, such as the great survey departments, little or nothing would be done in the way of actuallv producing the international sheets.

At the Geographical Congress at Rome in 1913 the scheme as formulated in London was accepted generally, but there was a feeling that a more comprehensive official conference was needed in order to put the matter before those countries not hitherto represented officially. Accordingly, after some correspondence between the British and French Governments, it was agreed that the latter should issue invitations to an official conference to be held in Paris in Dec. 1913. Thirty-four states sent representatives, and a very thorough examination was made of the London resolutions. In the main they were accepted, and the modifications made were not in matters of principle but of detail. The scheme had in fact got into a definite standard form, and the *Carte du Monde au Millionième* is now a world undertaking on lines accepted by practically all civilised countries.

The Paris Conference took an important step in approving of the establishment of a " *bureau permanent,*" comprising a central office to be located at the headquarters of the Ordnance Survey at Southampton, with a branch office in London, at the Royal Geographical Society, where visitors to London can obtain all information with regard to the international map and its progress.

Maps for War Purposes.—The Conference came to an end on Dec. 18 1913, but the report was not published when War broke out early in Aug. 1914. The effect of the War on the scheme was twofold. First, it resulted in the immediate cessation of all work on the map so far as the belligerent countries were concerned; but in the second place it led to a demand for maps on, or about, the one-to-a-million scale, and so in England and France, particularly the former, much official cartography was carried out on the million scale, and a large series of maps was produced by the initiative of the General Staff.

This important series comprises 90 maps extending from the Persian Gulf to the Arctic Ocean, and from the western shores of Ireland to beyond the Caspian Sea. Its sheets were selected by the Peace Conference for use in determining the new European frontiers. It differs from the regular international series in small technical details. The international map, interrupted by the War, has since been taken up again and satisfactory progress has continued to be made.

The trench warfare of 1914–8 in France and Belgium created a demand for maps on a larger scale than had hitherto been in general use by great armies, and large scale maps became indispensable for the operations of trench warfare particularly in connection with the use of artillery. With regard to that portion of the line which passed through northeast France, the 1:80,000 map, the best then available, was enlarged to 1:20,000 which made an unreliable map. Bit by bit, these enlargements were corrected and eventually all the maps of the Western Front were redrawn from special surveys, air photographs and revised cadastral manuscripts, the chief scale in use being 1:20,000. The map showed the enemy's trench system in detail, and all the maps were provided with a system of " squares," or co-ordinates, which enabled any point to be defined within a few metres. The use of " squares," or co-ordinates, is typical of modern military maps. An example of a typical trench map of the Western Front on the scale of 1:20,000 is shown on the plate[1]

---

[1] 1. The large rectangles on the map lettered A, B, C, etc., are divided into squares, 1000 yd. side, which are numbered 1, 2, 3, etc. Each of these squares is subdivided into four minor squares of 500 yd. side. These minor squares are considered as letters a, b, c, d (see square No. 6 in each rectangle). A point may be thus described as lying within square B.6, M.5, b, etc.

2. To locate a point within a small square, consider the sides divided into tenths and define the point by taking so many tenths

Progress of Cartography.—Modern topographical maps in- asingly use colour. The old black, engraved maps were beau- ul as specimens of engraving, but were never very easy to d, and in no case did they convey so much, or such accurate, ormation as do the modern topographical maps printed in e or six colours. But it is doubtful how long the modern col- red map will last; the paper is not nearly so durable as that ich is used for the printing of copper-engraved maps, and the ours are in some cases none too permanent. These remarks ply with special force to the "layered" maps; changes in the aes of the layers will greatly alter their character.

Topographical Maps.—In Great Britain the new popular ition of the ordnance map on the scale of one inch to one mile in colours with contours at 50 ft. intervals. It is completed England and Wales and is one of the best topographical ps in existence. The new quarter-inch ordnance map, in er form, is completed for Great Britain. An excellent map Roman Britain has been published by the Ordnance Survey. Canada an important series of topographical maps on the le of one inch to one mile is being published by the Dept. Militia and Defence. These maps have been in progress since 07. About 90 sheets have been issued covering an area of out 40,000 sq. m. in the provinces of Ontario and Quebec. e only complete series of topographical maps of the Union of uth Africa are those of the Orange Free State; these are on the ale of 1:125,000, or about half an inch to one mile. They were inted by the geographical section of the General Staff. There s been a marked improvement in the character of the topo- aphical maps of India. Up-to-date methods of colour printing ve been adopted with success. India, also, has produced the rgest block of sheets yet published of the regular series of the ternational map.

Ceylon is gradually being covered by an admirable series of e-inch maps in colour. The new one-inch map of the Federated alay States is a very satisfactory production. The mapping Kenya and Uganda, which has made good progress, was opped by the War and has not been resumed. Work is being rried on in the Gold Coast and Nigeria and in the Sudan.

The admirable and well-known series of maps of the U.S. Geo- gical Survey continues to be issued. The production of the borate French 1:50,000 series in colour was completely stopped ring the War; it is now being published in a simpler form. The alians are mapping Tripoli and Italian Somaliland on the 1:100,- o and 1:50,000 scales, and the map of Italy on the 1:100,000 th brown contours and vertical hachures is a clear and useful ap. The map of Spain on the 1:100,000 scale in colours, published by the Spanish General Staff, is in progress. There is an excellent series of maps of Denmark on the 1:400,000 scale, published in colours by the Danish General Staff, and some fine maps have been issued by Norway. A good start is being made with the mapping of Poland.

Bibliography.—For examples and criticism of various kinds of topographical maps, see A. R. Hinks, *Maps and Survey* (Cambridge, 1923); C. F. Close, *Text Book of Topographical and Geographical Surveying* (Stationery Office, London, 1925); see also R. D. Salisbury and W. W. Atwood (U.S. Geological Survey), *The Interpretation of Topographic Maps* (Washington, 1908). (C. F. Cl.)

MARC, FRANZ (1880–1916), German painter, was born at Munich July 4 1880, the son of the painter, Wilhelm Marc; his mother was of French extraction. He studied at the academy in Munich under Hackl and W. von Dietz. For the first seven years of his career as a painter he showed little originality. The decisive impulse came only when he got into touch with the group of painters including Kandinsky, Jawlenski and Macke who founded the "Blue Knight" (*Blauer Reiter*) in 1911. One of his most famous pictures entitled "Tierschicksale" (Destinies of Beasts) is characteristic of his whole work, which is singularly compact, not merely in choice of motive, but also in pictorial composition. A certain leaning towards metaphysics, towards abstraction from the world of reality, gives many of his pictures a problematic character. He also wrote a series of articles pleading the cause of the new painting. Marc was killed near Verdun on March 4 1916.

MARCH, FRANCIS ANDREW (1825–1911), American philologist (*see* 17.688), died in Easton, Pa., Sept. 9 1911.

MARCH, PEYTON CONWAY (1864–), American soldier, was born at Easton, Pa., Dec. 27 1864. He graduated from Lafayette College in 1884 and four years later from the U.S. Military Academy. He graduated from the artillery school in 1898, and on the outbreak of the Spanish-American War went to the Philippines, remaining there three years and rising to the grade of lieutenant-colonel of volunteers. After honourable discharge from the volunteers in 1901 he was appointed captain of artillery in the regular army. From 1903 to 1907 he was a member of the general staff and in 1904, during the Russo-Japanese War, was with the Japanese Army in Manchuria as observer. He was promoted major in 1907, lieutenant-colonel in 1912 and colonel in 1916. Soon after America's entrance into the World War in 1917 he was made a brigadier-general, U.S.A., and later major-general of the national army and in Sept. 1917, major-general of the regular army. In 1917 he was with the A.E.F. in France in charge of the American artillery forces. In March 1918 he was appointed acting chief-of-staff, and the following May chief-of-staff with the rank of general. On June 30 1920 his rank reverted to that of major-general, and at his own request he was retired from active service Nov. 1 1921. As chief-of-staff of the army, he reorganised the War Dept., consolidated the regular army, National Guard and national army divisions into a single army—the U.S. Army; and initiated and carried into execution a programme which landed in France, by the time of the Armistice, 2,000,000 men.

MARCHAND, JEAN (1883–), French painter, was born in Paris Nov. 22 1883. He studied at first with Bonnat and Merson (1902–6), after which he deserted conventional teaching, and exhibited for the first time at the Salon des Indépendants in 1908. He visited Russia and England on several occasions. Though Marchand came under the influence of cubism between 1910 and 1912, his work in general was not greatly affected by it. His human forms are treated with power and discretion, while his landscapes and still life are tinged with an intense melancholy. Exhibitions of his work were held at the Carfax Gallery, London, in 1915 and 1919. Among Marchand's pictures may be mentioned "Les Gueux" (1906); "Le Départ" (1910); "Suzanne au Bain" (1911); "Trois Baigneuses" (1912); "Le Carafe" (1913); "La Gardienne du Foyer" (1914); "Nocturne" (1915); "Le Soir" (1919).

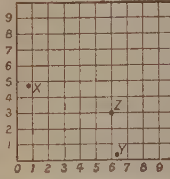
MARCHAND, JEAN BAPTISTE (1863–), French general and African explorer, was born at Thoissey (Ain) on Nov. 22

---

m W. to E. along southern side, and so many from S. to N. along stern side, the S.W. corner always being taken as the origin, and e distance along the southern side being always given by the first ure. Thus the point Z would be 63; *i.e.*, six divisions east and three visions north from origin.

3. When more accurate definition is wanted (on the 1:20,000 or 10,000 scale) use exactly the same method, but divide sides into o parts and use four figures instead of two. Thus 0847 denotes 08 rts east and 47 parts north of origin (see point X). Point Y is 03.

4. Use 0 but not 10; use either two or four figures; do not use actions ($8\frac{1}{2}$, $4\frac{1}{2}$, etc.).



The system of reference by squares shown the map and described above was used roughout the War by the British armies on e Western Front. Although clear and simple practice it was not ideal for gunnery pur- ses. For this reason it was decided shortly fore the Armistice to supersede it by another d more universally useful system.

Colours.—The topography was represented three colours. The detail including towns, uses, railways, roads, woods and grid lines and numbers, was inted in grey, water in blue and contours in brown.

Military details such as trenches, battery positions, mine craters, stacles, etc., were shown in blue (British) and red (German). ritish trenches were not shown *in extenso*, but only for such dis- nce from the front line as might be assumed to be already well sur- eyed by the enemy.

Conventional Signs.—The signs used for objects of military nature anged considerably during the War as the result of alteration of pes of defensive and offensive works.

1863. After four years' service in the ranks, he was, in 1887, appointed a sub-lieutenant. In 1889 he was on active service in Senegal, was twice wounded, and made a chevalier of the Legion of Honour. In 1898 he carried out his historic occupation of Fashoda (*see* 1.341), and for this he was promoted to commander in the Legion of Honour, having been previously raised to the grade of officer. In 1900 he became lieutenant-colonel, and was made colonel two years later. Shortly after the outbreak of the World War he was appointed to command the Colonial Brigade of the XIV. Corps, and in Feb. 1915 was promoted a temporary-general of brigade. In the following May he assumed command of the 10th (Colonial) Division. He was wounded in Sept. 1915, and was made a grand officer of the Legion of Honour. On March 25 1916 he was made a substantive-general of brigade. On April 4 1917 he was promoted general of division and confirmed as commander of the 10th Colonial Division. He retired from the army in 1919 and was given the grand cross of the Legion of Honour in the following year.

MARCONI, GUGLIELMO (1874–), Italian wireless telegraphy inventor, was born at Bologna on April 25 1874. His father, Giuseppe, was an Italian country gentleman who, in 1864, married Miss Annie Jameson, daughter of Mr. Andrew Jameson of Daphne Castle, County Wexford, Ireland. The issue of the marriage was two sons, of whom Guglielmo was the younger. He was educated privately at Bologna, Florence and Leghorn. As a boy he took a keen interest in physical and electrical science. In 1895 the idea became firmly rooted in his mind that a system of telegraphy through space could be provided by means of electric waves, the existence of which had been foreseen mathematically by Clerk Maxwell in 1864 and later investigated experimentally by Heinrich Hertz, Oliver Lodge, Righi and others. Interesting scientific experiments had been carried out in London and elsewhere with these electric waves, but Marconi was the first to devise the practical means by which they could be made to provide a new and revolutionary method of telegraphic communication.

In the early summer of 1895, Marconi conducted a number of experiments at his father's country house at Pontecchio, near Bologna. These experiments, made with crude and inefficient apparatus, soon began to give results which appeared to Marconi to be remarkable, communication being established in that year over distances in excess of a mile. The first considerable advance which he made was his discovery of the marked effect of the simultaneous use of elevated transmitting and receiving aerials connected to the ground through the generators (transmitters) and detectors (receivers) of electric waves. He discovered that by connecting one of the spheres of the spark-gap by means of a vertical wire to a metal plate buried in the earth, he was able to multiply many times the range of communication for a given amount of power.

In his receiver Marconi used the form of coherer, or sensitive detector, employing nickel and silver filings, connected to the earth and to an elevated conductor, in the same way as was done at the transmitting end, and provided with connections to a relay and other mechanical arrangements, which made it capable of receiving and recording the impulses of telegraphic signs transmitted through space from the sending station. In these early days, Marconi also discovered that the distance of communication increased very rapidly if the height above ground of the elevated aerials was increased. This fact was pointed out in his first patent and was also clearly described in a letter dated Nov. 14 1896 addressed by him to Mr. William Preece, afterwards Sir William Preece, engineer-in-chief of the British Post Office.

In 1896 Marconi came to England, and on June 2 of that year took out the first patent ever granted for wireless telegraphy based on the use of electric waves. He continued his experiments in London, and in the same year demonstrated his invention before officials of the Post Office and other representatives of British and Foreign Govt. departments. These demonstrations were first carried out on the roof of the General Post Office, St. Martin's-le-Grand, London. Later experiments for the Post Office were carried out on Salisbury Plain and acro the Bristol Channel from Penarth to Brean Down, near Westo super-Mare, ranges first of two, then of four, and afterwards nine miles were obtained.

In June 1897, at the invitation of the Italian Gov Marconi went to Spezia, where a land station was erected an communication with Italian warships was established up to distance of 12 miles. He was then invited to demonstrate h apparatus in Rome, where successful tests were carried out the presence of the late King Humbert and Queen Margherit Other tests also took place at the Italian Chamber of Deputie

The time was now almost ripe for wireless telegraphy to h applied to commercial and utilitarian purposes, and in Jul 1897 a company was formed in London to acquire the Marco patents in all countries except Italy. This company was calle the Wireless Telegraph and Signal Company Limited, which i 1900 changed its name to that of Marconi's Wireless Telegrap Company Limited. For some time the company's efforts we confined to furthering Marconi's pioneer work. A number interesting tests and demonstrations were undertaken round th coasts of the British Isles and abroad. Permanent stations we erected at Alum Bay in the Isle of Wight and at Bournemouth this station being subsequently removed to Poole, 14 m. fro Alum Bay.

Wireless telegraphy was first used for commercial purposes i 1898, when the Kingstown regatta races were reported for *Th Dublin Express* by Marconi by means of wireless apparatu installed on a tug which followed the yachts in the Irish Sea In the same year, during Cowes week, Marconi was called upo to establish wireless telegraphic communication between Osborn House in the Isle of Wight and the Royal Yacht "Osborne," t enable the late Queen Victoria to communicate with the Prince o Wales, later King Edward VII. In this year also wireless teleg raphy was first employed as a means of communication betwee lightships and the shore by installations on the East Goodwi lightship and the South Foreland lighthouse, separated by a dis tance of about 12 miles. The utility of wireless in saving life at se was demonstrated for the first time when, on March 3 1899, tha lightship was run down by a steamer. The accident was at onc reported by wireless to the South Foreland, enabling life-boat to be promptly sent to the assistance of the light vessel. I March 1898 Marconi established communication across th English Channel between England and France. During thi year wireless was also first utilised in the naval manoeuvres fo communication between warships over distances of 74 miles The first military application of wireless took place during th South African War.

During this period numerous improvements embodied i patents taken out by Marconi were utilised. On April 26 190 he applied for a patent for "tuned or syntonic telegraphy a well as multiplex telegraphy with a single aerial." The importa novelty was the incorporation of tuned closed with tuned ope circuits in both the transmitter and receiver. This patent, th number of which was 7777, became famous in the history o wireless, and its validity was upheld in the High Court by a decision of Mr. Justice Parker. The principles on which this patent was based were fully described in a lecture given by Marconi on "Syntonic Wireless Telegraphy" before the Society o Arts in May 1901.

In Oct. 1900 the erection of a long distance wireless telegraph station in Cornwall was commenced by Marconi and preliminary tests were carried out up to a distance of about 20 miles. On Dec. 12 1901 Marconi, on his first attempt, succeede in transmitting and receiving signals across the Atlantic Ocean from Poldhu in Cornwall to St. John's, Newfoundland. This achievement completely confirmed Marconi's opinion that electric waves would not be stopped by the curvature of the earth and therefore could be made to travel any distance separating any two places on our planet, a view he had held for many years in the face of considerable opposition. The wireless conquest of the Atlantic may be regarded as the culminating point of Marconi's pioneer work.

n 1902 Marconi, during a voyage on the American liner S.S. hiladelphia," received messages up to a distance of 700 miles day and 2,000 miles by night, thus first discovering the now l-known fact that wireless signals can usually be received r much greater distances at night than during the hours of light. Marconi read a paper dealing with this phenomenon ore the Royal Society on June 12 1902. At the time his clusions were severely criticised and his results doubted, but r experience completely confirmed his observations. In 1902 rconi designed and patented a practical form of magnetic ector based on the effect of electrical waves on iron or steel n subjected to a varying magnetic field. This magnetic re- er replaced the receivers up till then in use, and for over ten rs remained the standard receiver on the great majority of -going vessels equipped with wireless.

n 1905 he took out his patents for the horizontal directional ial, which marked an advance in the design of long distance tions. During the same year, in a lecture delivered before the yal Institution, Marconi first pointed out that most probably eless transmissions right round the world to places near the ipodes would be carried out with greater ease and at lesser enditure of electrical energy than would be necessary to much rer places. Later results fully confirmed the correctness of se views. In 1910 Marconi, assisted by Mr. H. J. Round, re- ved signals and messages at Buenos Aires from Clifden (Ire- d) over a distance of about 6,000 miles. In 1912 he devised a method for generating continuous waves, commonly known "the timed spark system." This system was employed for eral years at many important long distance stations and by means Marconi sent the first messages ever transmitted by eless from England to Australia on Sept. 22 1918.

In 1916, during the World War, experiments were commenced Marconi in Italy with very short waves, with the object of ising a directive, or beam system, of wireless telegraphy for r purposes. This was a principle on which he had also worked ring his earliest experiments, but work on these lines had n put on one side in favour of the use of longer and longer ves combined with higher power. Later, in England, with the istance of Mr. G. S. Franklin, important results were obtained the use of 15-metre waves between London and Birmingham. e result of the tests with short waves carried out in 1916 d 1922 were fully described in public papers by Marconi and anklin in 1922. (*See* WIRELESS TELEGRAPHY.)

These anticipations of Marconi were fully justified by the re- ts obtained since that time with short waves by British and eign experimenters. Marconi was the first to discover in Oct. 24 that short waves of the order of 30 metres in length could transmitted and received over the greatest distances during ylight. Short waves have proved themselves capable, even en used with a minimum of power, of carrying out com- nications by night as well as by day over any distance, even the antipodes. Marconi demonstrated that short waves are ch more amenable to control than long waves and they have very great advantage over long waves that by the use of itable reflectors, or by an efficient system of directive aerial, ey can be directed in a beam as light waves are directed from lighthouse or searchlight.

Marconi stated publicly that this possibility of focussing and recting short electric waves would soon be applied universally d that except for broadcasting and shipping purposes it would longer be necessary to send out waves at random in every rection.

During the World War Marconi served in both the Italian my and navy. He also visited America as a member of the alian war mission to the United States Government. In 1919 e King of Italy appointed him plenipotentiary delegate to the ace Conference in Paris, and in that capacity he attended the eetings of that conference and signed on behalf of Italy the ace Treaties with Austria and Bulgaria. He also attended in e same capacity the meetings of the commission on mandates ld in Paris and in London, and in other ways rendered valu- le services to the Allied cause.

The value of Marconi's work has been recognised by governments, universities and learned societies all over the world. Amongst the many scientific awards granted to him may be mentioned the Nobel Prize for physics in 1909, the Albert Medal of the Royal Society of Arts, the Franklin Medal and the John Fritz Medal awarded to him in the United States for the "invention of wireless telegraphy." In the same year he was nominated by the King of Italy to be a member of the Italian Senate.

Every great invention, when it has become established, has given rise to controversy as to who was the real inventor. Doubts have been expressed as to whether Marconi was in fact the inventor of wireless telegraphy. In the interests of historical truth, therefore, it is worth while to make the following quotation from the judgment given by Judge William K. Townsend of the United States Circuit Court of May 4 1905, in the action Marconi Wireless Telegraph Company of America versus De Forest Wireless Telegraph Company:—

> "It would seem, therefore, to be a sufficient answer to the attempts to belittle Marconi's great invention that, with the whole scientific world awakened by the disclosures of Hertz in 1887 to the new and undeveloped possibilities of electric waves, nine years elapsed without a single practical or commercially successful result, and that Marconi was the first to describe and the first to achieve the transmission of definite and intelligible signals by means of the Hertzian waves.
>
> The exact contribution of Marconi to the art of spark telegraphy may be stated as follows: Maxwell and Crookes promulgated the theory of electrical oscillations by means of a disruptive discharge; Hertz produced these oscillations and described their characteristics. Lodge and Popoff devised apparatus limited to lecture or local experiments or to such impracticable purposes as the observation of thunder storms. Marconi discovered the possibility of making these disclosures available by transforming these oscillations into definite signals and, availing himself of the means then at hand, combined the abandoned and laboratory apparatus and by successive experiments reorganised and adapted and developed them into a complete system capable of commercially utilising his discovery.
>
> Other inventors, venturing forth on the sea of electrical movement, met the rising tide of the Hertzian waves and allowed them to roll by without appreciating that this new current was destined to carry onward the freight and traffic of the world commerce. They noted their manifestations, suspected their possibilities, disclosed their characteristics, and hesitated, fearing the breakers ahead, imagining barriers of impracticable channels and shifting sand bars. Marconi, daring to hoist his sail and explore the unknown current, first disclosed the new highway.

(F. G. K.*)

MARGARINE (*see* 17.704) was first made from fresh beef fat freed from tissue and digested at a temperature of about 110° F. with the pepsin obtained from pigs' or sheep's stomachs, rendered alkaline by a dilute solution of sodium carbonate. The process of manufacture was improved from time to time, and before the end of the War the product, particularly vegetable margarine, was so like butter in texture, flavour and appearance that it was difficult to distinguish from the product it was made to imitate. Generally speaking, three types of margarine exist: (*a*) animal margarine, (*b*) vegetable margarine and (*c*) mixed margarine.

Varieties of Margarine.—Animal margarine has as a basis the material called *oleo oil* which is made by pressing *premier jus* by hydraulic presses, so as to separate the liquid oil (oleo oil) from the hard fat (stearine). *Premier jus*, as the name implies, is the first running of fat obtained by heating the fatty tissues of the caul and the kidneys of cattle at a temperature not exceeding 100° to 120° Fahrenheit. This fat is washed with brine and allowed to crystallise or "grain," and is pressed to obtain the oleo oil.

The fatty basis of vegetable margarine usually consists of a hard fat mixed with a liquid vegetable oil. The hard fat in this case is usually either about 25% of hardened (hydrogenated) oil, or 65 to 70% of cocoanut or palm-kernel oil. As liquid oils, cotton seed, arachis, soya bean and many others are used in accordance with the price and quality of the product desired. All these materials are subjected to a very drastic process of refinement and deodorisation. In the case of mixed animal and vegetable margarine the solid fat is either *premier jus* itself or *oleo stearine* (*i.e.*, the residue left after pressing premier jus).

Whichever type of fatty basis is used it is subjected to a process of incorporation with milk. Skimmed milk is generally used for the purpose, not so much for the sake of saving the cost as because it is more readily obtained, and has greater bacterial purity than whole milk. The skimmed milk, previously pasteurised, is placed in vats (ripening tanks), and is there inoculated with a pure culture of lactic acid-producing organisms—mainly *Bacillus acidi lactis* Leichmann—which coagulate souring milk.

The temperature is carefully controlled and, in a scientifically organised factory, the souring to the required extent is arranged to take place by a definite time. Great care is taken to keep the culture free from adventitious organisms which would produce undesirable flavours and impair the keeping properties of the finished product. Mould fungi are specially undesirable as they produce an unpleasant rancid flavour in the margarine, particularly when made with vegetable fats.

When the milk has reached the desired state of sourness, it is churned with the fat, with or without artificial colouring matter, in specially constructed jacketed churns fitted with beaters for finely incorporating the previously melted fat with the soured milk. This churning process has to be carried out with great skill, care being taken to maintain the correct temperature and to stop the churning at the exact point when the emulsion reaches its maximum thickness, as continued churning causes the mass to become thin again. Various types of emulsifiers other than churns are in use, some of which are very efficient. When the emulsion has reached the desired state, the product is then finished by either the wet or the dry process.

Wet Process.—In the wet process the emulsion is projected against a violent spray of iced water, which causes the emulsified fat to solidify in fine globules; the solidified mass which is produced subsequently floats on a tank of cooled water, from which it is removed and mechanically worked until the desired consistency is obtained. Salt and preservative, if any, are incorporated into the mass together with more colour. About 30% of milk is used in the wet process.

Dry Process.—The dry process is more economical, and little more than half the amount of milk is then required. In this process the emulsion from the churns is run in a gentle stream on to large rolls cooled inside with brine. The emulsion, as it solidifies on the surface of the rolls, is scraped off by knives and then worked on tables, kneaders and rolls, in the same manner as in the wet process.

Admixture with Butter.—Margarine, like butter, must not contain more than 16% of water. The admixture of butter with margarine to the extent of more than 10% of the former is prohibited. This regulation is still in force, though it seems originally to have been made to dispel the fear of the farmer that butter might be adulterated with small quantities of margarine to make such an excellent product that his trade might suffer, and that the public might be defrauded. Modern methods of analysis are able to determine the percentage of butter fat in margarine to within comparatively narrow limits, which was not the case when margarine was first invented.

Margarine usually contains 0·25% of boron preservative, except the type termed "fresh-roll," in which no preservative is used; at present up to 0·5% of boron preservative is permitted, but under new British regulations which will come into force in 1927 no preservatives will be permitted. The nutritive value of margarine has long been a subject of discussion. The chemical composition of butter is very similar to margarine, which actually gives the same number of calories or heat units as butter, and an average margarine is as digestible as an average butter. The average butter is characterised by considerable vitamin content, whereas margarine is practically devoid of any such characteristic. (See W. Clayton, *Margarine*, 1920.)

(E. R. B.*; R. G. P.)

MARGATE, England (*see* 17.704), with an area of 2,961 ac. (including 468 ac. of foreshore), had a population of 46,475 in 1921. Parts of Garlinge and Northdown were added to the borough in 1913. A town-planning scheme, providing for an industrial zone at the back of the town and restricting the number of houses to the acre elsewhere, has been put into operation. The town is ver healthy, the death-rate being usually under 10 per 1,000. Th municipality owns over eight miles of seafront, with promenad along almost the whole distance. A pavilion and winter garde have been erected in a hollow on Fort Green, and a pavilion o the jetty; the path along the cliffs to Kingsgate has been made int a wide promenade, with a new bridge at Palm Bay; a seawall an undercliff promenade have been built, and a large bathing pavi ion is (1926) in course of erection. A wing for tuberculous e service men was opened at the Royal Sea-bathing Hospital i 1919, and a public library in 1923. The War Memorial is i front of Holy Trinity church. During the widening of the Mi ster-road in 1922 an Anglo-Saxon cemetery was discovere During the World War 156 bombs were dropped on Marga and 44 shells were fired from the sea; considerable damage wa done, but the casualties were few.

MARGHILOMAN, ALEXANDRE (1854–1925), Rumania statesman, was born at Buzeu July 4 1854. He studied law an political science in Paris. In 1884 he was elected a deputy as member of the Conservative party, of which he became leader i 1914. At the beginning of the World War, Marghiloman adv cated Rumania's neutrality and when in 1916 Bratianu offere him a portfolio in his cabinet, Marghiloman refused on th ground that he could not assume the responsibility of an insuf cient military preparation. He remained in Bucharest under th German occupation, where he organised the relief work for th population. He emphatically rejected the proposals of the Ge man commander to form in Bucharest a government for th purpose of concluding a separate peace. In March, 1918, Marg iloman went to Jassy at the request of the King and formed government which eventually signed the separate peace wit the Central Powers. This treaty, however, was never ratifie When the War ended Marghiloman ceased to play any part Rumanian politics and after his death in Buzeu, May 10 192 the Conservative party ceased to exist, its members joini Gen. Averescu's (People's) party.

MARGUERITTE, PAUL (1860–1918), French novelist (*see* 1 706), died Dec. 30 1918 in Paris. His later works included *Maison brûle* (1913) and *Jouir* (1918).

MARIE, Queen of Rumania (1875–   ), was born at Eas well Park, Kent, Oct. 29 1875, the eldest daughter of Alfre Duke of Edinburgh, second son of Queen Victoria. On Jan. 1893 she married Prince Ferdinand, afterwards King of R mania. From this marriage six children were born: Prin Charles, who married Princess Helen of Greece, Princess Eliz beth, married to the ex-King George of Greece, Princess Mar later Queen of Yugoslavia, the Princes Nicolas and Mirc (d. 1916) and Princess Ileana. The Queen was a Protesta but the children, in accordance with the Rumanian constitutio were brought up in the Orthodox faith. Queen Marie took great interest in the development of her adoptive country. R Cross and charity organisations were formed at her initiati and, as a Red Cross nurse during the World War, she looke after the wounded in hospitals and ambulances up to the firi line. Queen Marie devoted much of her time to writing, a her published works include *The Lily of Life* (1913), *My Coun* (1916), *Stealers of Light* (1916) and *Ilderim* (1925). Together wit King Ferdinand, Queen Marie was crowned at Alba Julia O 15 1922.

MARINE ENGINEERING (*see* 25.840c).—At the present ti there are three distinct types of marine engines, and these may grouped as follows: (1) steam-engines with coal-fired boilers; (2 steam-engines with oil-fired boilers; (3) internal-combustion en gines, such as the Diesel or semi-Diesel type. Of course, groups (1 and (2) may be reciprocating steam-engines, turbines (geared o otherwise) or combined turbine and reciprocating. The thre types are described below.

Reciprocating Marine Steam-engines.—To-day, all marin reciprocating steam-engines are stage expansion engines, that i the steam expands in stages from the highest pressure cylinde through the intermediate stages, and finally exhausts into th condenser. Modern stage-expansion engines may be grouped a lows: *Compound.*—In this type there are two cylinders, the h pressure and the low pressure. Steam performs its function the high pressure cylinder; from there it passes into the low ssure cylinder, completes its work on this cylinder and ally exhausts to the condenser. *Triple Expansion.*—In this gine, as its name implies, steam exerts its power in three stages ore exhausting to the condenser. *Quadruple Expansion.*—In s type the steam is used four times before exhausting to condenser, two intermediate cylinders being fitted.

No marked improvements have taken place in this type of me mover, except as regards engine refinements, the general ign remaining the same. The advent of the marine steam bine and the marine internal-combustion engine certainly led many shipbuilders to install one or the other of these es; but it is interesting to note that in some recent large amers, notably the Peninsular and Oriental "Naldera" and arkunda," the carefully balanced triple-expansion engine been installed. Experiments are being carried out to utilise am at a much higher pressure than formerly, and excellent ults are expected.

ombined Reciprocating Engines and Steam Turbines.—An ellent example of this arrangement is the White Star "Olym-." The arrangement has proved an economical one, and is as lows: Each wing propeller shaft is driven by a reciprocating gine, the low pressure cylinder of which exhausts into a Par-s low-pressure turbine driving the centre shaft; 21 double-led cylindrical boilers supply the necessary steam.

Marine Steam Turbines.—(*See* TURBINES, STEAM.) The advan-ges of this prime mover which has led to its adoption during past few years are as follows:—

a) Fewer working parts, as no slide valves, piston and connecting ls are required.
b) The steam is supplied direct from the boilers with no inter-ing loss.
c) Considerably less danger of breakdown.
d) Engines placed well down in vessel (a big asset in warships).
e) Less expenditure of lubricating oil.
f) No cylinder lubrication is necessary, and clean feed water is urned to the boilers.
g) Absence of vibration, a big factor in warships and passenger mers.
h) Smaller attendance required than in the case of reciprocating ines.
i) Superior governing, good parallel running and even turning vement.
k) Priming, which would fracture the cylinder covers of a steam iprocating engine, has no material effect on a turbine.
l) Overloading (forcing the engines) can be indulged in within sonable limits.
m) More economical except at the lowest speeds.

The large-sized turbines are more economical in steam per sepower developed than the best triple or quadruple expan-n engine, as the turbine is able to take full advantage of the ole of the expansive energy of the steam. The two types in neral use are the Parson combined impulse and reaction tur-e, and the Brown Curtis impulse turbine. There are, natu-ly, many modifications of these types.

eared Turbines.—These turbines are coming into favour re and more. The chief trouble with the marine turbine arose h the propeller. It is necessary that a turbine for maximum ciency should run at a high rate of revolution, whilst for ximum propeller efficiency, much lower rates of revolution necessary. The solution for this was by the introduction of ne form of gearing between the turbine and the propeller. eral forms of reduction gearing are being experimented with, h as the electrical, hydraulic and mechanical. Mechanical ring appears at present to show advantages over the other ms—an efficiency of over 98% being obtained in the case of gle reduction, and over 97% with double reduction. There is ctically no limit to the ratio of reduction. Double reduction ring finds favour for the following reasons: (*a*) the type per-s larger ratio between revolutions of turbines and propellers hout excessive size of gear wheels—higher revolution of tur-es permits, for the same power, smaller turbines, and increase the number of turbines for the same power further reduces the size of each unit; (*b*) high revolutions or greater blade speed are possible, resulting in a nearer approach to the point where the blade speed in relation to steam speed gives maximum economy; (*c*) a small turbine permits of a pivot thrust block being used, as the dummy can be omitted, and all unbalanced load taken by the block; (*d*) small turbines have small rotors and can thus be made of a much more robust construction; (*e*) variations in temperature for any single turbine are kept moderate, and these turbines are therefore suitable for use with superheated steam; (*f*) the parts being smaller, the turbines can be more easily overhauled, repaired or renewed. America favours the electric drive for her navy and mercantile marine.

Marine Internal Combustion Engines.—One of the principal reasons which has led to the adoption of the internal combustion engine for marine propulsion is the thermal efficiency of this prime mover. Compared with a steam engine (reciprocating), and coal-fired boilers, we find: Diesel 40% to 45% thermal efficiency, according to size; steam engine 20% to 25%. As regards running, the fuel bill is about half that for an oil-fired boiler ship fitted with geared turbines; very great saving of space occupied by the machinery; reduction of personnel.

Against these advantages we have the greater initial cost; complication of parts; a greater number of spare parts have to be carried; it is probable that the repair and upkeep bill will exceed that for steam units. Before a big reduction can be made in initial and upkeep costs, all parts must be standardised; and the engines should be built in combinations of various numbers of cylinders for various powers and revolutions. For a given power the Diesel compares unfavourably as regards weight with the steam turbines and oil-fired boiler combination, and the head-room is greatly limited (this, especially from a naval point of view, is a marked disadvantage). The possibilities of this prime mover are endless; but up to the present the Diesel has not been installed in the largest ocean-going liners or cross-channel mail packets. There is no doubt, however, when a speed of, say, 25 knots can be reached, combined with a reliable and simple design of engine, we shall see the mammoth type of internal combustion ship breaking the Atlantic records. The largest ship up to the present with Diesel engines installed has a length of 600 ft. and a breadth of 72 ft.; and another Diesel-engined vessel of 20,000 tons is under construction. The present types work on the two-stroke or on the four-stroke principle; but many competent authorities affirm that the marine oil engine of the future will be a double acting two-stroke with port scavenging—this design giving an engine of low initial cost and simple construction. The solid (or mechanical) injection of the fuel is likely to be generally adopted in preference to the air injection system, owing to the reduction in first cost that is obtained by its use. Experiments are now being carried out with geared Diesel engines, and these will be watched with interest.

Marine Boilers.—It is only within the last few years, comparatively, that the water-tube boiler has been seriously considered as a rival to the cylindrical, or water-tank, boiler. The experience gained after many years with the cylindrical marine boiler proved it to be undoubtedly a good, safe, easily understood generator and also comparatively easy to clean. This type may be said to be the principal boiler of the mercantile marine. For naval purposes, of course, there can be no question as to which type is suitable; but even with such highly trained engine-room ratings as the British Navy possesses the advent of the water-tube boiler was not looked upon at all with favour. Although water-tube boilers are being fitted in increasing numbers in the mercantile marine, their many advantages do not appear to be recognised to the extent they should be, this being due in part to the high initial cost and also to the fact that the fuel consumption is inferior to that of the cylindrical type. However, the outstanding features of the water-tube boiler (*i.e.*, they are much lighter and give greater horsepower for the same space) should further recommend them. The modern trend is toward much higher working pressures, higher temperatures and the more efficient burning of the fuel and generation of the steam in the boiler. There is no reason why pressures of 700 lb. or 800 lb.

per sq. in. should not be reached. Superheating of the steam, air preheating, increase in boiler feed water temperature and careful analysis of the funnel gases are all receiving due attention, as are also the best means to adopt to ensure the cleanliness of the internal surfaces and tubes, and thus prevent or retard corrosion. Zinc slab protection is, to a certain extent, being superseded by electrolytic protection. In this system electrolytic conductivity is produced in the boiler water by a current of electricity from a source outside the boiler to metallic anodes insulated from the boiler shell, the current being regulated at will.

Oil Burning in Marine Boilers.—Within the last few years oil fuel burning has made rapid strides, and but for the question of cost would be much more generally adopted. As an example of saving in boiler-room staff, after the Cunarder "Aquitania" was converted to burn oil, her firemen were reduced to 42 as against 320 when coal-burning. The advantages of oil fuel are: superior evaporative power per weight of fuel carried, giving increased radius of action—1 lb. of oil with a heat value of 19,000 B.T.U. will evaporate 15 lb. of water to and at 212° F., and 1 lb. of coal with a heat value of 14,500 B.T.U. will evaporate 10 lb. of water to and at 212° F.; ease of shipping into bunkers and putting into fires; less stokehold staff and bunker space required; absence of coal dust and ashes; no necessity to open furnace doors with consequent loss; proper regulation of combustion; capability of forcing the boiler. Against those advantages we have: uncertainty of obtaining supplies; complications of piping and machinery; possible leakage; special appliances are required for burning; liquid and solid impurities found in the oil; widespread contamination of water-ways.

Liquid fuel is atomised by one of three methods—steam, compressed air, pressure. The last method is generally adopted in modern marine practice due to the reliability and freedom from breakdown of pressure systems. The system as now adopted is very simple; oil is drawn from the bunkers and strained, which removes all solid impurities. The oil is delivered from the fuel pumps under pressure, an air vessel assisting in maintaining a steady supply. Next, the oil passes through cold filters and thence to the heaters. The heating process may form particles of carbon in the oil, which are removed by passing it through filters fitted on the delivery side of the heater. From these filters, called hot filters, the oil passes under pressure to the distribution boxes on the boiler front, and from there through the burners (where it is atomised) to the furnaces.

Marine Auxiliaries.—The great increase in the number of auxiliary engines now fitted in modern steamships necessitates as much attention as do the main propelling machinery. As regards design, the majority of auxiliaries follow accepted practice; but the following units call for special consideration.

Condensers.—The modern method is to insure high vacuum combined with reliability, and that the weight of the apparatus shall be as low as possible consistent with the work the condenser is called upon to perform. Separate air pumps are installed, one pumping out the feed water, and the other maintaining a high vacuum by pumping air from a cooler part of the condenser. Tube failure—through corrosion—is a frequent source of trouble, and the many experiments now being carried out with tube metal mixtures have not eliminated this.

Electrolytic protection has been adopted with good results. Metallic packing for the tubes, in place of the ordinary tape packing, has recently been introduced, and the results are excellent. In connection with modern condensers a system has been devised known as the "closed feed system." By this method the condensate is removed from the condenser and discharged to the boiler without exposure to the atmosphere; thus preventing air mixing with the feed water and causing boiler corrosion. Another method now coming into favour is the removal of the air in the feed water by mechanical de-aeration; and this method seems to possess advantages over the removal of the air by chemical means.

The Michell Thrust Block.—This block possesses marked advantages over the older form of multiblock. The device consists of one collar on the shaft, the thrust being taken by a series of
pads capable of a slight rocking movement. The pads maint
a continuous flow of oil between the metal surfaces, which
thus kept apart by as many oil wedges as there are pads to p
duce them. This block is essential to the satisfactory worki
of gears now fitted in many modern ships.

(1924); R. Sennett and Sir H. J. Oram, *The Marine Steam Eng*
(1924). (F. J. D.)

MARINES (*see* 17.719). *Great Britain.*—Marine forces in so
instances constituted the whole or the main part of forces t
off for coastal descents, *e.g.*, the British expedition to Ostend
1914 and the Zeebrugge enterprise of 1918. In others they und
took emergency land operations for which no other military fo
was available, *e.g.*, in the case of the Royal Marine Bde.
Antwerp, 1914; or again, as in the case of the U.S. Marine Bde.
France, 1917–8; and the British 63rd (R.N.) Div., which
cluded marine units, in the composition of a land army in c
tinuous operations. In several instances the marines pro
formed a soldier nucleus for formations of which the princi
part was made up of sailors, as the British R.N. Div. and e
more so the German Marine Corps. France used improvis
battalions and brigades of sailors (Fusiliers Marins) in the sa
way, and a brigade of these under Rear-Adml. Ronarc'h w
undying glory by its defence of Dixmude during the first batt
of Ypres and the Yser.

The German Marine Corps was composed originally as
division partly of marines and partly of sailors, who were nume
cally far in excess of naval requirements. It took part in
siege of Antwerp and the advance through Flanders. Wh
stabilisation came the division was raised to the strength o
corps, and the corps commander (Adml. Schroder) was ma
responsible for the Yser front, for coast defence between Ni
port and the Dutch frontier, and for purely naval operati
based on the Belgian coast, having both submarines, surf
craft and aircraft under his command for the purpose. Final
the German corps formed a third mobile division which was s
to any point on the Western Front where reinforcements w
needed.

The Royal Marines, 1914–8.—Just before the outbreak of
World War the total strength (all ranks) of the British Corps
Royal Marines was 18,000. During the War, however,
strength of the corps increased steadily, until at the end
numbers had been more than trebled, due to the formation
new units within corps. In 1914 the R.N. Div. was formed; va
ous divisional units of Royal Marines were raised for service w
it, such as engineers (transferred to the Royal Engineers in 19
medical units and transport. The R.M. Submarine Min
(1917), the R.M. Labour Corps, the Home Service Lab
Corps (1917) and the R. M. Engineers (1918) were raised. Spe
units were also provided separately and compositely by
R.M. Artillery and the R.M.L.I. at various times.

In all naval actions, and in naval patrol duties, the Ro
Marine personnel took a part. In the early days of the War
sonnel of the corps served with the armoured cars operating fr
Dunkirk. Four battalions of the brigade took part in the defe
of Antwerp. Details from two R.M.L.I. battalions were invol
in the landing at Kum Kale and Sedd-el-Bahr (March 4 19
and marine artillery siege guns were used at Dunkirk. The co
sent a battery to Egypt in 1916 for coast defence duties. Deta
ments served also in Cameroon, in the Persian Gulf and
Adml. Troubridge in Serbia, and formed the nucleus of the he
batteries which were raised for service with Gen. Botha in Sou
west Africa and with Gen. Smuts in East Africa. The cor
furnished gun crews for armed merchantmen and garrisons
naval bases as at Scapa, Cromarty and St. Helena, and for t
coast defences at the North Foreland, in the West Indies
elsewhere. (X)

United States.—The United States Marine Corps is a separa
military organisation under the administration of the Na
Dept., and as such it forms a part of the naval establishment
the country. It was founded on Nov. 10 1775 when a resoluti
of the First Continental Congress authorised the raising of t

alions of marines to assist the continental navy in the de-
c of the colonies. In organisation, training and duties this
e was modelled after the British marines of that date. From
ı to the present the marines have continued to serve as an inte-
part of the U.S. Navy; although under the authority of con-
sional enactment portions of the corps have been temporarily
ıched for service on shore with the U.S. Army.

he laws provide that marines may be assigned to the follow-
luties: to garrison the different navy yards and naval stations
ıin and beyond the continental limits of the United States;
ırnish detachments to serve aboard the battleships and cruis-
of the fleet where they form one of the gun divisions of the
, perform military guard duties and act as a landing force
ı the fleet or squadrons as required; to act as expeditionary
ling forces for service with the fleet to capture and defend
ı positions as may be required as temporary naval bases for
fleet; to furnish the first line of the mobile defences of naval
ions and bases beyond the continental limits; and, when
ial conditions make it advisable, to be temporarily trans-
ed for service with the army.

he marines have taken a conspicuous part in every war in
ch the United States has been engaged and have also seen
h foreign service in the peace-time occupation of foreign
ntries for the protection of American citizens and property
ing revolutions and unsettled conditions, in furtherance of
diplomatic policies of the United States.

efore the Spanish-American War in 1898 the marine corps
sisted of 75 officers and 2,000 enlisted men, but was increased
eafter, and at the entrance of the United States into the
rld War in 1917 it consisted of 511 officers and 13,124 en-
d men, and during that War a total of 31,824 marines were
overseas for service with the A.E.F. The Fourth Brigade
larines formed a part of the Second Division of the A.E.F.,
re they served in many campaigns and battles with conspicu-
gallantry and gained many citations and decorations. The
ce-time operations of organisations of the marine corps have
uded expeditions to China, Cuba, Nicaragua, Mexico and
ama, for the protection of American interests, and the recent
ıpations of Santo Domingo and Haiti to insure the peace
stability of these countries under treaty obligations between
n and the United States. The mission of the marine corps
er the stated naval policy of the United States is: "To sup-
the fleet, or any part thereof, in the accomplishment of its
sion." The emblem of the corps is a hemisphere with the map
he Americas thereon, superimposed upon a foul anchor and
nounted by an eagle with spread wings. The motto of the
ps is "*Semper Fidelis.*" (D. W.*)

ARINESCU, GEORGE (1864–), Rumanian neurologist,
born at Bucharest Feb. 23 1864. He was educated at the
ılty of medicine of Bucharest and then went to Paris where
worked under Dr. Charcot at the *Salpêtrière*, carrying out
ıable researches on the histopathology of the nervous system.
ear later he went to Frankfort and worked with Professor
gert. He then continued his research work on nervous dis-
s in Berlin and Brussels. In the latter town he published his
k on the treatment of epilepsy for which he obtained a prize
n the *Académie Royale de Belgique*. In 1900 he was appointed
fessor of neurology at the University of Bucharest. In the
ımn of 1916 Professor Marinescu went to London where the
lical Research Committee made him a whole-time grant. At
L. C. C. Maudsley Hospital, Denmark Hill, in collaboration
ı Lt.-Col. F. W. Mott, F.R.S., he applied himself to an
ortant series of researches upon the microscopic structure of
ve cells and their changes in different phases of activity or
ıage. He also took an important part in the investigation of
nervous system in some cases of *Encephalitis lethargica*.

ARINETTI, FILIPPO TOMASO (1878–), Italian writer,
born at Alexandria Dec. 22 1878, and studied in Paris,
luating at the Sorbonne; in 1899 he also graduated in law
he University of Genoa. He was the founder of the futurist
ement, publishing the original futurist manifesto in the Paris
ıro on Feb. 20 1909. For a time he edited the international review *Poesia*, but his most characteristic work was *Mafarka le futuriste*, published in French in 1910. He also wrote for the stage *Le roi Bombance* (1905), a satirical tragedy, and other plays, and published a volume on the futurist theatre, *Teatro sintetico futuristo* (1916). In 1914 he wrote an extraordinary volume entitled *Zang-tumb-tuuum* on the Balkan war, and particularly on the siege of Adrianople. Other futurist essays are *Noi futuristi* (1917), *Manifesti del futurismo* (4 vol., 1920), *Democrazia futurista*. On the outbreak of the World War he was strongly in favour of Italian intervention, as he showed by his volume *Guerra sola igiene del mondo* (1915). *Otto amici in mia bomba* deals with war experiences; while in *Futurismo e fascismo* (1922) he expresses his support of the Fascist movement. Marinetti's futurism, though violent, exaggerated and sometimes ridiculous, is a quite genuine reaction against the excesses of the academic and hidebound tradition in literature and art.

MARKBY, SIR WILLIAM (1829–1914), Anglo-Indian jurist (*see* 17.730), died at Headington Hill, near Oxford, Oct. 15 1914.

MARKETING.—Marketing is essentially buying and selling. The central fact is the sale, but to secure sales the goods must often be assembled from the places where they were produced, graded when qualities differ, sorted when there are different varieties, moved to market and in many cases thence to the place of consumption.

I. IN THE UNITED STATES

Methods of Marketing.—The simplest form of marketing and the most primitive is the sale by the producer directly to the consumer. In the aggregate, sales made in this way even at present run into immense volume, although but a small part of the total of business. Modern business, the development of large cities, an increasing division of labour in industry, all tend to reduce this form of marketing. There is still a considerable amount of marketing of produce, particularly butter and eggs, direct from farmers to consumers, by parcel post and by direct sale. Again, certain specialities, complicated machines and machines requiring much attention and service after the first sale, usually are sold direct by manufacturers to consumers through the medium of speciality salesmen. The salesman is the representative of the producer in the marketing transaction. Again, if a retailing house does so large a business that it can advantageously engage in manufacturing some of the lines of goods it sells, it may combine production with distribution.

Most products of common use, such as foods, clothing, footwear, house furnishings, lumber, fuel and so on, are marketed through middlemen. The manufacturer of men's clothing or of shoes usually sells his product to retailers scattered over the country, who in turn sell to consumers. Manufactured food products, dry goods, drugs, hardware and house furnishings are generally sold first to wholesalers, who in turn sell to retailers.

Farmers' produce, fruits, vegetables, butter and eggs, are commonly marketed through local buyers, then to wholesalers or wholesale distributors, then to retailers and lastly to consumers.

Variations in Method.—Variations are introduced into marketing in many ways. The actual sale may be consummated through personal salesmanship either in the seller's place of business or in the buyer's. If the seller carries a line of goods he must have a store or shop, but even this may not keep him to one location. The old-time pedlar carried his store on his back. More recently grocery stores, meat shops, book and periodical shops and even dry goods and house furnishings have been put on wheels, on automobile trucks and sales routes laid out to be covered periodically, making sales direct to housewives and consumers. Again, the sales may be effected through retail institutions by mail. In the United States a gigantic business has been built up by a few large mail order houses which are really stores or shops selling retail to consumers. Some wholesale concerns selling only to retail dealers have developed enormous businesses founded on the mail order method of selling. In addition to these there is an unknown but certainly large amount of business transacted by ordinary retail and wholesale stores by mail, supplementing personal selling.

Wholesale Marketing

In the case of highly perishable goods, such as fruits, where no time may be lost in effecting sales in order that they may reach the consumer before spoiling, the auction system is used. Wholesale buyers and salesmen come together at a designated place at a set time and clear their transactions. The auction is a much more widely used mechanism of trade in England and in continental Europe, where large quantities of nearly all kinds of goods are thus sold, than it is in America, where the system is declining. In addition to its use in the marketing of perishable goods it occurs, to a limited extent, particularly in lines of known standards or qualities, which are bought and sold in wholesale quantities at certain dates each year, as carpets, rugs, wool, furs and fruits. It is also a common method of marketing second-hand goods, works of art, antiques and even real estate.

Variation in marketing occurs through variation in ownership of the goods to be marketed. To illustrate: producers or local buyers usually sell outright to wholesalers all goods marketed through the wholesaler-retailer channel of distribution; but in highly perishable goods, such as fruits, dressed poultry, live poultry, etc., and also in cases where the value of the goods runs very high in proportion to the value of the service rendered by the wholesale middleman—as, for example, finished textiles, real estate, commercial paper and stocks and bonds—the wholesaler (or dealer who takes his place) frequently, if not usually, merely sells or buys as the agent of the owner and secures a commission or brokerage instead of a profit for his services. This arrangement in the case of perishable goods relieves the wholesale dealer of the risk from loss, and, in the case of costly goods, of the burden of financing the goods. Such wholesalers are known variously as commission dealers and brokers.

Function of Speculation.—While goods are being gathered together in wholesale quantities and made ready for distribution to the retail trade other factors in marketing frequently enter in, factors of a speculative nature. Standardised goods that are not readily perishable, such as grain, cotton, wool, silk, provisions, coffee, sugar and so on, are likely to be bought purely for speculative purposes. Thus a lot of grain or cotton may be bought and sold several times before being moved to consumption. It is but another step for these speculators to make their ventures in hope of gain on what they think future prices will be. Hence "selling futures" is a common occurrence on the great exchanges that deal in the commodities named.

Under this system grain may be bought and sold long before it has been harvested or grown, or even before it is planted. (*See* GRAIN TRADE.) A flour-miller may quite legitimately ensure his future supply of grain at a certain price by buying "futures." But a great deal of opposition has been aroused at various times by speculation in the necessities of life. It has been charged that dealing in futures enables powerful speculators to combine unjustly to secure success for their ventures, in some cases tending to hold prices down and in others tending to hold prices up. As a result both producers and consumers are suspicious of such traders. The consensus of opinion among those who have studied the course of speculation on exchanges seems, however, to be that if manipulation of prices and monopoly can be kept out of the market, and if the laws of supply and demand are allowed to operate freely, the effect of speculation, particularly of dealing in futures, has a healthful balancing effect on the market. Under such conditions purchase and sale of commodities for future delivery tend to discount and equilibrate all conditions of supply and demand, so that changes of price are made much more gradually than they would be if buying and selling of such commodities were confined solely to the stock offered each day. Dealing in futures is an essential function of marketing, but it needs careful regulation to prevent unfair practices.

Methods of Marketing.—If producers are many and small, and are located far apart, it is almost certain that their products will have to be assembled by a local buyer of some kind; whereas if the producers are able to turn out large quantities they may be able to deal with wholesalers direct.

If consumers use small quantities or small lots of any product at one time it is almost certain that they must purchase from retailers. But a large consumer would be able to buy more advantageously direct from the producer.

Some articles cannot be sold more than once or twice in a lifetime to a customer. If it also happens that such articles require much demonstration and explanation, then the producer is almost forced to sell direct to the consumer or have his sales made by special representatives or agents. Subscriptions to high-priced periodicals, adding machines, life insurance and real estate are illustrations of goods that need such specialised attention.

Time is a very important element in the marketing of peri able goods. There must be no delay, and little time can be giv to the sale of any particular unit. An illustration of a perisha article is the daily paper, the weekly or monthly magazi Timeliness is the essence of their value. This makes necessa a highly specialised marketing organisation to carry papers magazines over the country and, in the case of magazines, place them on sale everywhere at the same time. Such specialis handling calls for expense not incurred in goods not perishab

A low-priced article with a small margin of gross profit to seller cannot be sold in the same way as an article that offer wide margin. In the former case the margin above costs production could not permit the article to be sold direct or to advertised and sold by itself by the mail-order method. It mu take its way to the consumer through the channels of tra followed by thousands of similar articles.

Competition.—The competition in the sales field of any arti might readily determine the channel of distribution that taken. Certain manufacturers of soaps, perfumes and toi goods have found it so difficult to place their products advan geously in drug stores and similar retail outlets because of number of competing lines that they have found it advisable sell, especially in country districts or small towns, direct consumers by means of agents and canvassers working on commission basis. A motor-car tire maker found it so diffic to break into the market through automobile dealers and gara that he sold his product to a mail-order house.

A new product must as a rule be sold through specialised m keting systems which may be abandoned after the public h begun to know the article.

THE COSTS OF MARKETING

Table I. contains figures compiled from actual records by Harvard Bureau of Business Research, Harvard University.

TABLE I. *The Retailing of Shoes: A Comparison of Costs*
Net Sales 100 per cent

	Lowest	Highest	Usual
	%	%	%
Independent shoe stores:			
Low priced shoes . . .	13·3	32·33	20·5
High priced shoes . . .	23·43	32·85	28·8
Chain shoe stores . . .	9·85	57·60	24·6
Department store:			
Shoe departments . . .	19·0	33·4	23·5

It is clear that the statistics do not prove that in the case of sh either chain stores or department stores can be conducted at expense than independent stores. It is true that the lowest fig for chain stores is considerably lower than any other, but the ch stores also show the highest costs. The average costs of selling chain stores seem to run a little higher than in independent lo priced shoe stores and in department stores.

Table II., showing cost of marketing,[1] is compiled and adapt from reports of the Harvard Bureau of Business Research, Nor western University Bureau of Business Research, several natio trades associations and personal studies.

Costs of selling through mail-order houses are not officially kno They are supposed to range from 18 to 30% of sales. But the kno edge of a general figure of this kind for a large mail-order house w many departments would be of little value even if correct. Costs selling vary from department to department in mail-order ho just as in department stores. To be of value in a comparison selling expenses, the figures should show the cost of selling shoes, example, by mail. All things considered, the general costs of runn a large mail-order house are probably somewhat lower than tho for a large department store handling similar classes of goods.

The mail-order establishment need not be in a shopping distri so that the rent or investment represented by its size is comparative small; the employees who fill orders do so more rapidly and for le pay than those who sell in a store; advertising is usually confi to the less expensive publications, and in the case of the larg houses the customers are much more numerous, running into m lions. Costs in the shoe department of a mail-order house should r lower than in a department store or speciality shop because in t mail-order house there is no time and labour lost in fitting sho

---

[1] Costs of retailing in other lines of merchandise, so far as t figures are available, show about the same relationships. T example presented may be taken as typical.

TABLE II. *Marketing Costs*
Percentage on Sales

	Wholesale			Retail		
	Lowest	Highest	Usual	Lowest	Highest	Usual
	%	%	%	%	%	%
utomotive Equipment	16	26	23·5	15	29	24

ectrical Supplies	10	20	14	20	31	26
oceries	5	15	9	9	22	14
rdware	13	21	18	11	32	23
welry	15	20	18	24	40	32
oes	12	26	15	13	34	24
rniture				20	35	25
neral Merchandise				10	30	16
epartment Stores				18	32	28
ain Stores (Shoes)				10	57	24
ain Stores (5 and 10c)				..	..	26
ain Stores (Groceries)				..	..	16
ain Stores (Drugs)				..	..	28

s saving is counterbalanced somewhat by the number of shoes ch are probably returned. The lower costs of selling in the mail- r house, however, are offset in part at least by the costs of trans- ation and other expenses incidental to ordering by mail.

conomies in the Chain of Distribution.—A part of the com- tive battle for trade among these various types of institutions sists in the utilisation of large buying power. Large chain e systems, mail-order houses and large department stores uently purchase their goods direct from producers and secure prices usually given wholesale purchasers. In some cases a of these differences may be used in cutting the prices to sumers, but it would be a mistake to assume that the con- er gets all the benefit from purchases made at lower prices, hat this entire difference is gained for the dealers. Concerns go direct to the producers, and thereby eliminate the whole- rs, as a rule incur practically all the usual expenses of whole- ng, such as interest on the investment in the larger stock of ds, storage risks, buying expense in dealing with numerous ducers instead of a few wholesalers, extra record-keeping , with chain stores, reshipments to their various stores ughout the country.

he only real saving which buying direct from producers in- s is the eliminated profit of the wholesaler, with a possible ction of the expense for salesmen whom wholesalers must loy. Competition in buying has forced the joint creation by ll concerns of buying organisations which, united, represent arge a buying power as the chain or department stores. operation in buying certain classes of goods has strong ad- tages both for dealers and consumers. Buying in group at time may secure advantages, not only in price but also in sportation and handling, sufficient to cover the added ex- ses incurred in buying in quantity. Since 1920 there has been pid development in group buying by independent retailers ll kinds. The competition of chain-store systems wielding rmous buying-power advantages has forced independent lers, both large and small, to associate for the purchase of y items, and in some cases for the joint ownership of full- d wholesale houses.

omparing the various methods of retailing as exemplified in ordinary independent stores, the department stores and the l-order house, from such facts as are available, it does not n possible to assert positively that any one method presents ded general economic advantages over the rest. Each pre- s advantages in point of service, but the difference in service ears to be fully compensated in expense—that is, the public s for what it gets and in proportion to what it gets.

So far as the public is concerned, it seems safe to say that there are large classes who prefer and who will always continue to prefer to trade in those retail establishments offering them the highest developments of service, the department stores and the independent speciality shops. Other large classes prefer and will probably always prefer to buy in stores offering less service and proportionally lower prices. Undoubtedly there are many who find their greatest satisfaction in purchasing in the stores of the self-service kind, where they may look about and pick up on their own initiative whatever they may wish to buy. Institutions are built to serve people in the way that they want to be served. There is room, therefore, in the retail trade for many types of stores. Speciality shops, department stores, chain stores and mail-order houses will all continue to exist as long as there are numbers of people who want the services each institution offers. It seems impossible to believe that any one type will monopolise the retail business or crowd out all the others.

Avoidable Waste.—The following statements outline briefly a few of the details of distribution which it seems certain must receive attention in order to secure more economical distribution. No doubt many more could be added. Poor roads greatly increase the costs of bringing the farmers' crops and produce to market, costs that must be added to the price that consumers eventually pay. Inadequate railway transportation is another element that makes a considerable addition to the costs. Car shortages at crop-moving time, cars unsuited to the products to be hauled, excessive delays in forwarding, at terminals, on the way and at transfer points, are common sources of expense.

Delay in transportation as a factor of expense in distribution has not been given the attention that it deserves. Poor location of terminals makes a great deal of expensive cartage necessary. Congestion of traffic in city thoroughfares is a growing cause of increased costs in distributing goods. Inadequate, inefficient, poorly located storage facilities cause huge losses. Inadequate, unauthoritative and inaccurate collection and dissemination of market information such as is needed by producers, distributors and consumers is responsible for great wastes. Through lack of such information business in many lines now passes constantly from glut to famine and back again. Poor packing of merchandise, inefficient loading, rough handling and uneconomical methods of handling are causes of waste and therefore of higher costs of distribution.

To refer more specifically to the activities of marketing through wholesalers and retailers, there is a startling loss of the wholesale salesman's time in finding customers, in making appointments, in fruitless interviews. The time of both salesmen and buyers is lost. Probably less than a sixth of a salesman's time, averaging salesmen of all classes, is actually employed in selling or even in displaying and describing merchandise. Anything that can be done to improve this deplorable economic condition will increase efficiency and decrease costs. No one can even begin to estimate the losses resulting from poorly trained salespeople who fail to sell and who waste the time of their purchasers through lack of knowledge of their goods, their customers' wants and their business, or through lack of ability to use their knowledge properly. Owing to lack of incentive most employees give but a fraction of their ability to their work.

Advertising.—Advertising is or should be an invaluable aid to marketing. In the list of expenses of distribution it occupies a prominent place. There is certainly room for improvement in its administration. Much study has been given in some organisations to such problems as the proper selection of mediums and the right use of the space taken. No doubt much greater progress can and will be made in the future in these directions, but the greatest loss in advertising seems to be in the lack of faith of the public in the advertising. If people gave more credence to advertising, much less of it would be needed to secure the same result. The remedy, of course, lies in the direction of raising the standards and shutting out the dishonest advertiser. (*See* ADVERTISING.)

Duplication.—Duplication in delivery organisations by retail stores is a source of economic waste. There are many who think that there are too many retail stores. Would goods be sold for less if there were fewer? Probably not, because a large part of the competitive losses now occurring are borne by the dealers themselves in unpaid services. It may be argued that if their number were reduced the rentals for the locations that would be eliminated could be saved. This cannot be definitely checked by such experience as has been recorded in any public way. Concentration of retailing seems invariably to result in increasing rents. In fact, rents tend to increase faster than sales, so that the fewer the stores the higher the share of the landlord. More studies are needed to determine the exact effects of restriction of the number of stores on costs of distribution. There is further the fact that the store plant is unused for a large part of the time. Store hours are by custom and legislation steadily growing shorter. This means that the capital invested in stock and plant has fewer hours in which to produce.

Dishonesty.—Finally, there is undoubtedly an enormous loss due to unfairness and dishonesty, a loss that is now carried in large part if not wholly as an expense of distribution, being added to the price paid by the consumer. Failure to return containers lent by distributors seems a small item, but in such a business as milk distribution in large cities the loss to milk distributors due to non-return of empty bottles is enormous. Uncollectable debts and the cost of collecting delayed payments are important items in the expenses of distribution. Disregard of contracts in such matters as refusal of goods after placing orders, failure to deliver goods after orders are placed, abuse of the privilege to return goods, claims for adjustment and many other similar items make up large losses. Unfair competition, efforts made not to increase legitimate business but to impede or even to destroy competitors, commercial bribery, "graft" and the exercise of monopoly, all burden distribution expense far too much. A source of considerable loss is theft by employees, burglars and shoplifters. Some retail establishments count upon a fixed percentage on their sales representing losses due to this cause, a percentage that is added to the gross expenses which form part of the selling prices. Many of the losses of the distributive business, including theft, breakage, fire and so on, are covered by insurance, the cost of which is carried as an expense against the distributing process. Anything that can be done to reduce these losses will by that much reduce expenses of distribution and prices of goods.

Education in Marketing

The leaks and wastes enumerated above are certainly responsible for at least a quarter of the present costs of marketing. They may be responsible for a third or even more. Here, then, is a great field for reducing costs by improving present methods. The first general step towards such improvement is education. A beginning has been made. Before 1860 the apprenticeship system was general in England and to some extent in America, in retail, wholesale and importing houses. The apprenticeship system gradually decreased about the middle of the 19th century, and for years after no systematic training was provided for young people other than the haphazard effect of their experience. The first training of modern salesmen in America seems to have been by the subscription book houses that flourished during the 'seventies and 'eighties. Their canvassers or book agents were thoroughly drilled or schooled in the art of selling or in securing orders. During the 'nineties sales managers in speciality manufacturing concerns, notably the National Cash Register Co., of Dayton, O., began training their men in special schools held at the factory.

Training salespeople for retail stores seems to have begun in the 'nineties in such subjects as arithmetic, spelling and writing and, in 1905, in sales methods, under the auspices of the Women's Educational and Industrial Union in Boston. Educational service to salespeople and other workers is now commonly found in the better classes of both wholesale and retail stores. A beginning has been made also in education in distribution and marketing in American colleges and public schools. Several colleges offer courses in marketing, selling, sales management and advertising. Many high schools give similar but more elementary courses.

The main drawback to a rapid development of public education in marketing seems to be a shortage of teachers who can cond
such courses rather than lack of public interest. Such an orga
sation as the United States Chamber of Commerce in its relat
to distribution is largely a clearing-house for information a
educational ideas for its members. One of the notable thi
in the progress made in educational work for marketing is
growing conception of the relation of the sciences of p
chology and sociology when practically applied to the pr
lems of marketing.

II. IN GREAT BRITAIN

Excepting the larger wholesale markets in England, situat
in Liverpool, Mincing Lane, E.C., and elsewhere, which han
cotton, wheat and certain other imported products, it may
asserted that much variety, extremely haphazard methods a
a considerable degree of inefficiency in organisation are
characteristics of the marketing process throughout the grea
part of England, Scotland and Wales. For this unsatisfact
condition many reasons may be given, not the least import
of which is the continued existence of market rights in the ha
of private individuals or joint stock companies or their assign
enjoyed under royal charter, Act of Parliament, or survivi
manorial rights.

Scarcely less important causes are the reluctance of the smal
British producers to form societies for co-operation in the s
of their output and the comparative ease with which, hither
a growing home market has absorbed an output which, especia
in the case of certain perishable products, has increased
rapidly than the demand. Again, improvements in meth
have not been necessary in the absence, until recently, of effect
competition from abroad in respect of most of the less import
commodities ordinarily handled in the provincial markets; w
the inability of many existing markets to cope with an incre
in the volume of business—an inability especially marked
some of the larger towns and arising mainly from the diffic
of reconciling numerous and conflicting vested interests—
rendered difficult any large-scale recasting of the marketi
process throughout the country.

*Location and Organisation of the Principal English Wholesale F
Markets: Fruit and Vegetables.*—The smaller centres of popu
tion have traditional and established market places originally
apart for the sale of produce direct from the growers to t
consumers. In the larger industrial towns these markets h
grown in importance (but not in physical dimensions) with t
growth of the towns themselves. Some have become re
markets whose continued existence it is not always easy to jus
on economic grounds; but others have become wholesale mark
especially in areas where local production is insufficient or err
and foreign imports are needed to ensure supplies, or again whe
transport facilities and favourable geographical situation h
permitted the extension of their spheres of influence and caus
them to become distributing centres for large areas. Many
these are well organised and are sensitive to price movements
other markets. Since, however, they draw a large proportio

. supplies direct from the producer, and these supplies are :e to fluctuation, they require an additional and a more re- e source from which to supplement the local output and from h special lines and imported supplies may be obtained to ıce demand.

ıis source they find in the central markets at important ports, especially in the Covent Garden market in London, which ecome a national distributing centre for fruit and vegetables. ately owned by the Covent Garden Estates Company, Ltd., market handles not only produce raised within carting dis- e of London, which is required for London consumption, but main crop produce in general demand, part of which is larly recodsigned to other distributing centres, and certain uce in limited demand or supply, such as glass-house produce h commands a high price and most of which is reconsigned her markets. Much of this reconsignment business is eco- ically indefensible; but it cannot be replaced entirely by t consignment to provincial markets until the latter become developed and price movements in them much less liable influenced by small alterations in supply and demand.

eat and Fish.—Wholesale meat markets are generally owned managed by local authorities, and exist only in those centres pulation (not more than 20 in number) where the magnitude ssible trade justifies their establishment and where retailers ssured of adequate supply with wide range of quality and s. In smaller towns the place of the municipally owned ket is taken by wholesale butchers who purchase live stock, ghter it and sell the meat to retail dealers; and in the City of field, where no meat market proper exists, the wholesalers t the slaughter-houses which they rent from the local author-

By far the largest and most important of wholesale meat kets proper is the London Central Market at Smithfield h in a single year handles between 400,000 and 500,000 tons, uding 40% of the total imports of meat into the whole try. Unlike Covent Garden, it undertakes practically no nsignment of produce to other wholesale markets; but its s for both home and imported meat (although not officially d under the imprimatur of the City of London Corporation, h is its owner and manager) are largely used as a basis for lesale dealings in other parts of Great Britain.

the foreign meat trade a network of depôts has been estab- d by certain large distributing firms in all the principal cities towns in the country. To them supplies of chilled or frozen meat despatched from the ports of entry. They, therefore, serve mall markets from which retailers can secure supplies with and promptness. The prices charged are fixed with reference mithfield and are, therefore, fairly uniform throughout Great ain; but local circumstances occasionally demand departure strict uniformity.

ish is handled at Hull, Grimsby, Fleetwood, Aberdeen and r ports, usually by Dutch auction, and is distributed by the lesale purchasers to their stalls and to representatives in in provincial fish markets (Birmingham, Glasgow, Liverpool, chester and others) and also to the very important Billings- market in London.

ereals.—Wheat is usually sold by sample in the local corn- ket nearest the producer's home. Certain of these small kets, however, attract a considerable quantity of grain from s outside their immediate neighbourhood, and some of the est dominate large tracts of country, frequently serving as ôts for the receipt of both home-produced and imported wheat for its export to other consuming centres. The purchasers hese local markets include millers among their number; but outright to merchants and sale by merchants or agents on mission are not uncommon, the latter being, perhaps, the l plan in Scotland. Producers' co-operative societies may be employed, which may sell direct to millers, or more uently to merchants whom the larger milling-firms find it e convenient to employ in their purchasing of home-grown at in bulk.

arley when sold for malting and distilling is usually sold in larger market-towns by merchants acting on a commission basis on behalf of the farmer. Oats are largely consumed on the farms of the growers, but direct sale by the producer to oatmeal millers is common. Merchants, however, frequently buy outright for sale to large consumers such as collieries and railway companies.

After wheat is milled it is usually sold direct to bakers, confectioners or other users, generally through travellers employed by the milling companies. Occasionally factors or wholesale dealers intervene, who purchase from millers for re-sale on their own account to small bakers in the more sparsely populated districts. Distribution by this method is uncommon, however, in the case of home-milled flour; although imported flour is nearly always handled by wholesale dealers of this kind.

At the next stage, that of baking, a few firms in several of the more important centres of population confine themselves to a purely wholesale trade. A fair number attempt to combine partial retail distribution with wholesale manufacture and usually possess retail shops where the bread is sold over the counter direct to the consumer or from which door to door delivery by van may be undertaken. The majority of baking firms, however, confine themselves strictly to retail trade, selling, in addition to bread, various forms of confectionery, such as cakes, sweets and biscuits, which may be either proprietary articles or manufactured by the bakers themselves; but certain difficulties, occasioned especially in the north of England by housewives buying bread at irregular intervals only, encourage distributors to cease manufacture themselves and to rely on wholesale baking firms entirely for the supplies which they need.

Poultry and Eggs.—Owing to the fact that British producers of poultry and eggs have no export trade to foreign markets, there is no obligation on them to conform to standardised methods in the disposal of their products. There is consequently great variety in the marketing of these commodities and the plan adopted by an individual producer depends partly on the scale upon which he is operating and partly on his situation relative to his market or his customers. Sale may take place (*a*) by private treaty in the producing area; (*b*) by auction in the producing area; (*c*) directly to distant distributors; (*d*) through commission salesmen in distant wholesale markets; (*e*) through co-operative societies. To the first of these classes may be assigned sales at local weekly markets of eggs and dressed poultry to local customers, sales by parcel post or rail direct to the consumer, sales from door to door often in conjunction with milk and vegetables, sale to local distributors in the nearest market town and sales at the farm. This latter plan is common throughout England and Wales, intermediaries known as higglers (also as cadgers and hagglers) going round in districts where the farms are scattered and distant from the larger consuming centres. The higgler calls at the farm with a vehicle once or twice a week, buys all the eggs and poultry available and pays cash without much regard to classification or to quality. He then resells privately or in open market to wholesale and retail distributors; but he may occasionally send consignments to wholesale markets for sale on commission.

The system of selling by local auction has been greatly extended in recent years. The Stirling live-stock mart is a good example, and the Kings Lynn market also is one that has lately made marked progress in this comparatively new development. For sale on commission the Smithfield and Leadenhall markets in London are utilised as well as the various wholesale markets in the provinces.

Costs of Distribution

The costs of distribution vary considerably with the nature of the commodity handled, the method adopted and the degree of efficiency in the market organisation available to the producer. In the case of cereals the fees paid by the farmers in the local corn-exchange are very small. Sixpence per day, one guinea per year, one penny on each occasion the market is entered, threepence per person entrance fee for sale by sample, are a few examples taken at random of the rentals and fees in actual operation at the present time. Cartage to the market or railway station is also the farmers' expense. This is reckoned at 1s. to 2s. 6d. per quarter of grain up to a distance of 8 to 10 miles. Merchants selling wheat on commission for growers are paid 9d. to 1s. per quarter or 2d. or 3d. per hundredweight. These figures are slightly higher in the cases of barley and oats. A rent ranging from 2 guineas to over 8 guineas per annum is charged to merchants who operate in the local exchanges and who require stands, desks or space on the market floor.

Fruit and Vegetables.—For fruit and vegetables the costs incurred in the complete marketing process are proportionally greater than in the case of cereals. Considerable expense arises in the preparation of produce for the market. Dressing potatoes for example costs 4s. to 5s. per ton. Cartage to railway station is estimated in Lincolnshire on the average to amount to 3s. to 4s. per ton. Railway charges are moderate and, on the whole, reasonable. In the distributive market itself porterage charges and market tolls are an additional burden and then there are the payments to the commission salesman for his services.

It is the practice of the commission salesman to supply the receptacles or containers needed by the producer and generally to act on the latter's behalf once the produce is despatched from the farm. When a sale has been effected the salesman remits to the grower the amount realised less the charges for use of containers, for transport, porterage, market dues and also a commission on the selling price for service rendered. The latter is nominally about 7½%, but actually in cases investigated by the Linlithgow Committee an average of 10 or 12% was found.

In its further passage towards the consumer the produce may find its way direct to the retailer from the commission salesman, or it may be sold to a commission buyer acting for a distant wholesaler, who in turn resells to the local retailers from whom the consumer buys. These agents who buy on commission may act merely on behalf of principals who cannot attend the market in person, or may themselves buy on their own credit and assume full responsibility for the produce and for bad debts, charging up goods at cost price, adding porterage-out and a flat-rate charge to cover labelling, consigning and the clearing of empties. In the former case they receive a flat-rate per package, handled (2d. in Covent Garden). In the latter they charge 2½ to 7½% on the cost price.

It is calculated that the wholesalers on whose behalf they act make a net profit of about 2% on their sales to retailers, and that the latter obtain a net profit of over 6% on the cost of the goods or a little under 4% on turnover. The diversity, however, of retail services demanded by the consuming public and the wide range of costs entailed cannot but make for uneconomic distribution of these products; it would not be correct to state that the middlemen actually engaged in the marketing process make profits that are unduly large.

Meat.—In the meat trade the following estimates taken from the Linlithgow Report exhibit well the costs incurred and prices paid and received in the passage of beef from the English farmer to consumers in larger industrial centres.

	£	s.	d
Farmer receives for one animal from dealer at local market	31	0	0
Farmer's expenses (tolls, etc.)		9	3
Farmer's net receipts	30	10	9
Dealer receives from wholesale butcher	32	10	0
Dealer's expenses (rail, tolls, feeding, etc.)		18	6
Dealer's net profit		11	6
Wholesale butcher receives from retailer	30	3	9
Wholesale butcher receives for hide and offals	3	10	6
Gross receipts of wholesale butcher	33	14	3
Expenses of wholesale butcher (slaughtering)		13	2
Wholesale butcher's gross profit		11	1
Retailer's receipts from consumers	36	9	10
Retailer's payment to wholesale butcher	30	3	9
Retailer's gross profit	6	6	1

The weight of meat sold in this instance was 690 pounds. The net price paid by consumer being £36 9s. 10d. and the receipt from offals being £3 10s. 6d. the difference between the net price received by the farmer and the total made by meat and offals is, therefore, the difference between £40 0s. 4d. and £30 10s. 9d., *i.e.*, £9 9s. 7d. The corresponding differences for Wiltshire bacon and for pork were £3 14s. 7d. and £1 16s. 6d. for weights of 140 and 148 lb. respectively.

The same Committee also collected figures showing the receipts from the sale of a forequarter of frozen beef weighing 187 lb. and costing £2 14s. 6½d. or 3½d. per pound. In this case £5 6s. 1½d. was realised, giving a gross profit of 48·6% on sales. In another case New Zealand lamb costing £1 17s. 4d. was retailed at £2 8s. 0d., leaving a gross profit of 22·2% on sales. When it is remembered that the expenses of the retailer in the case of frozen meat are substantially less than in the case of home-killed meat, owing to the absence of slaughtering and dressing costs, the very remunerative character of trade in foreign meat is readily perceived. Again, competition appears to be less active in the retail meat trade generally than it was before 1914, and this notwithstanding an increase in the number of establishments since that date. It would seem to be the case that butchers, having been encouraged to purchase collectively during the War period, still combine to keep down prices both of stock and meat; and further that retailers to a considerable extent agree on the prices consumers are required to pay and on the whole refrain from underselling one another in open competition.

In the distribution of bacon retailers usually purchase supplies of home-cured bacon direct from the factory; but in some cases they may buy from wholesale provision merchants. The margin obtained by the wholesaler is about 2½%. This is ample for the services he renders. The retailer's gross profit is more difficult to ascertain; for this trade is mainly undertaken by grocers who rarely separate it off from other departments of their business. It appears, however, that the profit on English bacon is from 10 to 14% of the sale price.

Poultry and Eggs.—In the selling of poultry and eggs at the lo market, apart from the cost of conveying the produce to the place sale, the vendor usually has to pay market tolls and, in the case sales by auction, the auctioneer's fee. The average tolls charg (by the local authorities who usually own the markets) are ½d. 2d. for poultry and from ¼d. per score to 6d. per 100 for eggs. Aucti charges generally range from 5 to 7½% of the price realised a consequently, are higher than those for selling livestock. This, doubt, is because of the smaller value of the individual lots put for sale. The higgler's profit in the districts where he flourishes from 1d. to 2d. per doz. on eggs. This is not excessive; but his ser ice, nevertheless, is not economical.

The dealer's business is more speculative, owing to the ra fluctuations in prices from day to day and from market to mark His average profit of from 2d. to 4d. per doz. on eggs is, therefo reasonable, especially as he provides boxes and pays transp charges. Commission salesmen's charge is 5% of the selling pri and wholesale dealers purchasing on their own account aim at gross profit on eggs of about 2d. per doz. and of 2d. to 3d. per lb. dead poultry. Probably it is in the retail section that profit margi in this trade are greatest and most open to question, 14% on e and 20 to 30% on poultry being the averages for the whole count Producers complain that the difference between the prices th receive for poultry and those paid by the public has increased d proportionately in recent years. The gross margin formerly cover profits and expenses of all intermediaries was roughly 1s. bird. The current margin is about 6d. per lb., which is approximat 1s. 6d. to 2s. 6d. per bird.

Co-operative Marketing

The organisation of producers on a co-operative basis for disposal of their produce and for the carrying out the proces involved in marketing is not a new development in Great Brita but the progress made is insignificant compared with what h taken place elsewhere. Figures in the returns furnished to Chief Registrar of Friendly Societies for the year ending Ma 31 1924, referring to societies operating only in England a Wales, establish the fact that roughly about 3½% of the to value of agricultural produce marketed in England and Wa was handled by co-operative marketing societies or co-operat societies with marketing branches. The following table wh is taken from No. 1, of the Economic Series published in 1 by the Ministry of Agriculture and Fisheries (Great Brita sets out in detail the position for the 12 months beginni April 1 1923.

The following table shows the number and turnover of agric tural marketing societies and certain other societies handling a cultural produce as part of their general trading during the per 1923–4. The table excludes turnovers in grain, hay, potatoes, e of general trading societies.

Commodity Handled	Number of Societies	Turnove
		£
Dairy produce	63	1,447,6
Eggs and poultry	43	349,26
Fruit and vegetables	18	301,9
Livestock[1]	9	375,1
Auction marts (livestock)	18	1,081,95
Slaughterhouses	11	415,2
Bacon factories	6	694,8
Wool	13	200,00
Total	181	4,865,9

[1] This entry covers societies selling livestock on behalf of memb otherwise than through an auction mart owned or rented by society.

[2] Turnover in respect of produce handled, and not necessarily to turnover of society.

[3] 1924 figures.

[4] Estimated value.

These 181 societies are widely distributed without any union centralising agency which might secure joint action or otherwise l after common interests. Attempts, however, have been made fro time to time to federate them or to institute an advisory body assist them to sell advantageously. The most recent project of th kind was the establishment in 1918 of the Agricultural Whole-sa Society with the object of buying and selling for such societi everything that is best bought or sold on wholesale lines. Th capital of this new wholesale body, however, proved inadequat and in consequence of a period of acute trade depression with insuffi cient resources and credit to enable it to surmount its difficulties i nt into liquidation in 1924. During its brief existence it seems to ve done more bulk purchasing of agricultural implements and ds than large scale marketing of produce; although it did set up a partment to market eggs and established a meat section to help co-operative slaughterhouses in their sales in Smithfield market. downfall involved the Agricultural Organisation Society in such ficulties that the latter body also succumbed a short time after.

Present Development.—The present trend is in the direction of several groups of societies forming their own trading federons on a commodity basis and thus falling into line with the neral course of development towards larger scale marketing d trade. One such central trading body is the English Farmers' con Agency. Another, the British Egg Producers, which took er the business of an earlier body of the same kind, has hardly t with the success it deserves; but a regional trading federation South Wales, called the South Wales Mutual Dairies, which a selling agency for four large dairy societies in Carmarthenre and Pembrokeshire, has had better fortune. There is also ather undefined union of fruit and vegetable marketing coerative societies of the counties of Worcester, Gloucester, arwick and those adjoining, which is growing into a trading leration; but, on the whole, the association of co-operative rketing societies for joint action in the conduct of the sale of eir produce is only very slightly developed in Great Britain.

Since 1900 many efforts have been made to establish trading ations between these agricultural producers' co-operative ornisations and the industrial co-operative movement. The 00 retail consumers' societies of the latter are said, approxitely, to feed one-third of the whole consuming population of eat Britain and are, therefore, in a position to offer an assured tlet for the produce of British farms. While some progress has en made in bringing the two organisations into closer reions it is obvious that the natural clash of interests between oducers and consumers must always make price-fixing difficult. this awkward point could be settled satisfactorily, much might done to eliminate the control now exercised by the many ddlemen in the marketing of agricultural produce. (*See* Co-ERATION, AGRICULTURAL.)

THE FOOD COUNCIL

The general dissatisfaction with retail prices during the years ceeding the period of War-time Government control resulted the appointment in 1922 of a departmental committee (the nlithgow Committee) of the Ministry of Agriculture and sheries to inquire into the methods and costs of selling and tributing agricultural, horticultural and dairy produce in eat Britain and to consider how the disparity between the ice received by the producer and that paid by the consumer uld be diminished. This was followed by a Royal Commission Food Prices in 1924 with terms of reference not very different. a result of the first (and only) report of the latter body a Food uncil was sent up to study current and future problems of eat and meat supplies and to issue periodical reports. This uncil is not endowed with any statutory powers. It seeks to rk by focusing public opinion on whatever it judges to be unsonable prices or unduly high profits; but it shirks definite ice-fixing and thus avoids many problems that presented emselves during the period of Government control and to ich no satisfactory solution ever was given.

MARKHAM, SIR CLEMENTS ROBERT (1830–1916), British ographer (*see* 17.734), died in London Jan. 30 1916. The ncipal work of his later years was connected with the two tarctic expeditions under Capt. R. F. Scott. An important history of Arctic and Antarctic exploration by Markham was completed posthumously by Dr. F. H. H. Guillemard and published in 1921 under the title of *The Lands of Silence*. A *Life*, written by his cousin, Adml. Sir A. H. Markham, was published in 1917.

MARNE, FIRST BATTLE OF THE, the series of actions fought in Sept. 1914, when the French and British Armies turned at bay between Paris and Verdun and defeated the Germans, driving them back to the Aisne.

The Germans had hoped to bring France to her knees in six weeks, but when four weeks had expired France and England were still keeping their opponent at arms' length. The Germans were indeed slightly ahead of their time table, but they had insufficient troops to carry out their grandiose plan. Antwerp and Maubeuge had necessitated a subtraction of strength and the invasion of East Prussia had led to the dispatch of two corps from the German right wing in France. Further, the rapid advance had led to considerable wastage and the comparative breakdown of wireless was hampering the invaders.

I. THE OPENING OPERATIONS

Advance on Paris.—The original plan had implied that if the French formed a great defensive flank resting on Paris, the capital was to be turned by forces pushed west and south of it; reserve divisions were to be dropped for the investment; and the five field armies, pivoting on Thionville, were to make a stupendous left wheel and to force the Allies against the Swiss frontier. By Aug. 28 this plan had begun to show signs of weakness. The German right wing was not strong enough and was too widely spread out. The II. Army was in comparative isolation and found itself committed to an advance against the great fortress of Paris.

This army was roughly handled by the French at the battle of Guise on Aug. 29 and its commander, Von Bülow, thereupon sent out urgent appeals to the I. and III. Armies on his right and left respectively to close in to his aid. These cries for help altered the whole course of the War. The commander of the I. Army was glad to switch off from the elusive British Army and decided to turn inwards. The hand of German supreme headquarters was now forced. They approved the scheme, although it meant giving up the advance on Paris. The new objective of the right wing was to be the flank of the French main forces opposite the II. Army. Envelopment was still held in view, but the net was to start its scoop east of Paris instead of west of it. Opposed to this wavering was the consistent policy of Joffre. An orderly retirement until he could gain the respite afforded by some topographical obstacle was his dominating thought. Here he proposed to reform and reorganise and then to assume the offensive at the earliest possible moment. The limits of the withdrawal were laid down as the territory immediately south of the rivers Seine, Aube and Ornain. A retirement so far would mean the isolation of Paris, but Joffre clearly realised that the fate of Paris would be decided in a battle fought, not under its walls, but in the open field.

Defence of Paris.—Paris was not undefended. It had, indeed, been proposed to declare it a *ville ouverte*, but the patriotism of its inhabitants decreed otherwise. The military governor was General Galliéni, who had under him four and a half divisions of *territorials*, some cavalry and field artillery, as well as 5,000 *fusiliers marins*. On Sept. 1 the newly formed VI. Army, some 60,000 strong, was placed under his command, and in addition he received Sordet's Cav. Corps, two reserve divisions and a particularly fine reinforcement in the shape of the 45th Div. from North Africa. Galliéni had therefore a respectable mobile force at his disposal, as well as garrison troops.

His first duty was the defence of the capital against which, so far as he knew, the German right wing was steadily advancing. The task was a difficult one, for the apathy and neglect of successive French governments had been reflected in the unreadiness of the fortress. By herculean efforts much was done in the limited time at his disposal, but Galliéni took a grave view of the situation. Then suddenly the whole situation changed. Up to the morning of Sept. 3 it seemed certain that the German right wing was advancing

on Paris with the Senlis-Paris road as the axis of movement; by the afternoon information, transmitted by aeroplanes and cavalry patrols, clearly showed that the German I. Army had switched off from Paris and was heading south-east towards the junction of the right of the British and the left of the French V. Army.

The situation in which Galliéni now found himself was one which demanded exceptional powers of decision. On the one hand there was the German I. Army making a flank march across the north-east of Paris, "trailing its coat" under the very eyes of the garrison, and providing a temptation almost impossible to resist. On the other hand there was the fact that Joffre had declared that he did not wish to undertake an offensive until he had got his army behind the Upper Seine and Aube. At 9 A.M. on the 4th Galliéni, anticipating the sanction of the commander-in-chief, directed the commander of the VI. Army to hold his troops in readiness for an advance against Von Kluck's exposed right flank. Next he communicated with Joffre and Sir John French. All three were equally desirous of assuming the offensive at the earliest possible moment and any divergence of opinion was only on matters of detail.

Joffre's Offensive.—Little reflection was necessary to convince Joffre that a chance not often met with in war was now vouchsafed him. He determined to assume the offensive from where he stood and shortly before midnight he issued his orders stating that advantage was to be taken of the situation of the German I. Army to concentrate against it the efforts of the Allied armies of the extreme left. All preparations were to be carried out on Sept. 5 and the attack was to be made on the 6th.

Disposition of the Forces.—At this moment the position of the Allied armies in France resembled a ribbon attached at its ends to Paris and Verdun and sagging slightly by its own weight in the centre. At Paris was the French VI. Army and other available troops. Next came the British Army. Then in succession the French V., IX., IV., and III. Armies, the right of the latter joining up with the mobile forces of Verdun. The initial orders included the VI., British, V. and IX. Armies only. The first was to cross the Ourcq and make for Château Thierry. The British were to be ready to attack in the direction of Montmirail. The V. Army was, generally speaking, to attack from south to north, its right protected by the IX. Army. During Sept. 5 supplementary orders were issued to the IV. and III. Armies, the general trend of which was that they were to attack inwards and thus to bring about a double envelopment of the German armies.

Facing the Allies were the five German armies to which had been entrusted the great turning movement pivoting on Thionville, numbered I. to V. from right to left. The French, British and German Armies thus enumerated were those immediately concerned in the operations now known as the battle of the Marne. Further to the southeast, between the fortress of Toul and the Swiss frontier, the German VI. and VII. Armies had been heavily engaged with the French I. and II. Armies since the middle of August.

During the evening of Sept. 4 a new directive was issued to the German Forces. By it the I. and II. Armies on the right were now to face west towards Paris. On the left the IV. and V. Armies, by a determined advance south-east, were to open a passage across the Moselle, in which region a lesser Sedan might yet take place. The III. Army in the centre was to push south ready to assist either wing as required. Thus Von Moltke was forced to abandon the hopes founded on the great massive wheel of five armies pivoting on Thionville and instead was compelled hurriedly to assign to his armies three divergent axes of march towards the west, south and south-east. In the new scheme it was Von Kluck's task to remain between the Oise and Marne. Instead of doing so he continued pushing on over the latter river. As the French VI. Army had been ordered to cross the Ourcq and to advance towards Château Thierry a collision between it and the flank guard of the German I. Army was now but a matter of hours. Almost exactly at noon on Sept. 5 a battalion of the French VI. Army came under heavy shell fire from the German flank guard. Some very heavy fighting ensued and by evening the French had made good a little ground, although at the expense of heavy casualties.

II. THE ACTUAL BATTLE

The battle proper may be considered as starting on Sept. 6. The French VI. Army moved out to the attack with both of its flanks protected by cavalry. By then Von Kluck had begun to comply with orders by withdrawing his troops across the Marne. The bulk of the day's fighting took place opposite the right wing of the French VI. Army and especially against the extreme right. It was soon evident to Gen. Maunoury, the French commander, that the German flank guard was being substantially reinforced. Von Kluck could, however, only reinforce his right flank at the expense of his front, and, in consequence opposite the British there was a noticeable slackening in the advance of the German I. Army. Put briefly, the relative situation of that army had changed. What had been its right flank—consisting of the IV. Res. Corps and a cavalry division—was by successive reinforcements, to become the front; while the original front, by a corresponding diminution, was transformed o the left flank, and the army as a whole was to face west tead of south.

The hesitation observable in the German advance was soon owed by an unmistakable retrograde movement. The British no time in seizing the heights on the Grand Morin south Coulommiers, from which German heavy guns had during morning brought an effective fire to bear. Save for some nting early in the morning about Rozoy—an action brought by the Germans to cover their retreat—the British were not vily engaged, though a few prisoners and machine-guns were en. To the right of the British, the French V. Army, after a ck early in the day, had made a substantial advance, the Gern I. Army was now in the position of having to fight desperly to hold off the converging attack of the French VI., the tish, and the French V. Armies.

The fighting on the Ourcq on Sept. 7 was hard and bitter. en at the risk of weakening himself elsewhere, even of causing ap between himself and the II. Army, Von Kluck had to bring ry available man to the fight. The effect of his action was t a gap, soon to yawn into a gulf of 30 m., was opened between German I. and II. Armies. Into this gap the British and the of the French V. Army were steadily pushing. In other ds, Von Kluck found himself committed to an isolated action h his left and rear exposed. Unless he could hold off the Brit- and the French V. Army sufficiently long to enable him to pose of the French VI. Army he was defeated. But for his k he had neither the time nor the men.

After a day of hard fighting the French VI. Army had made e further progress, and its front ran generally from Chamy through Barcy and Marcilly to the high ground west of vigny. The British were now opposed merely by German alry reinforced by Jäger battalions and were enabled to push ir line to La Haute Maison-Aulnoy-Chailly and Jouy sur rin. The French V. Army likewise made good progress, ching the line La Ferté Gaucher-Trefois. Further to the right fighting had been severe, the left of Foch's IX. Army being vily attacked and forced to call on the V. Army for help.

A somewhat disquieting feature of the day was the apparent ntion of the Germans to make another effort to turn the is-Verdun line at Nancy and at Troyon, where a successful ust would very seriously discount the French efforts on the cq. Worse still, Maubeuge fell on Sept. 7, and the invaders only gained another rail line of communication but had another corps available for operations in the field. Against se drawbacks, however, could be set the fact that the gap ween the German I. and II. Armies had considerably widd, and into it, the British Army and the left of the French Army were now advancing with speed.

Sept. 8 was remarkable for the violence of the German attacks ng the Ourcq. Maunoury's plan was to attack with his right tre and left, while the VII. Corps in the centre was ordered to l its line at all costs. That corps was heavily attacked early he afternoon, and such was the severity of the fighting that a k later the streets of Etrepilly and Trocy were still blocked h the bodies of the slain. To the north the French outflanking vement was brought to a standstill, while even the superb antry of the Zouaves of the 45th Div. on the right centre ed to make any considerable impression on the enemy. Dur- the afternoon Galliéni visited the Commander of the VI. Army his headquarters at St. Soupplets and pointed out that the ater the resistance offered by the Germans on the Ourcq the opposition would the British meet with in their advance. vertheless, Maunoury considered it advisable to make argements for a possible withdrawal on the following day. anwhile the British Army was discounting the efforts which Kluck was making on the Ourcq.

ir John French decided that the best method of assisting French VI. Army implied the speedy passage of the Petit rin and Marne rivers, for after passing the latter the British y would be facing northwest and thus almost directly threatg the line of retreat of the German I. Army. Orders were ordingly issued for a general attack along the line of the Petit Morin, to begin early on Sept. 8. At first the march was undisturbed, but on reaching the Petit Morin it was soon realised that the German cavalry would not yield without a struggle, especially as the steep valley covered with small but thick woods distinctly favoured the defence. Some severe fighting ensued, but by evening the British had made good the Petit Morin and were on the line La Noue-Viels Maisons, where they joined up with the II. Cav. Corps of the French V. Army, the left corps of which extended to the southern outskirts of Montmirail.

Sept. 9 was to witness Von Kluck's last effort on the Ourcq. The French VI. Army, although it had been reinforced, was at the end of its strength and its left was pushed back. A superb effort, however, restored the day and then it was clear that Von Kluck had shot his bolt. During the day the British crossed the Marne and on its right the French V. Army seized Château Thierry. Thus on the extreme west of the great battle things had gone well for the Allies, and it is now time to turn to the doings in the centre of the field.

German supreme headquarters had ordered the I. and II. Armies to form front facing Paris, the former between Oise and Marne and the latter between Marne and Seine, Château Thierry to be the point of junction of the two armies. This order had at first been disregarded by Von Kluck, who had persisted in his passage over the Marne and in maintaining his position in front of the II. Army. Von Bülow, however, endeavoured to comply with the orders of his superiors, and did make an effort to wheel his army to the right with the object of taking up the line Château Thierry (exclusive)—Marigny-le-Grand. The net result of compliance with orders by one army commander and disregard of them by the other was that the right corps of the II. Army was squeezed out of the line by the left corps of the I. Army. In other words, the two armies were acting upon different plans; overlapping had arisen; and the confusion inevitable in such circumstances began to be revealed upon the evening of Sept. 5. This factor alone was bound to hamper the II. Army, and Von Bülow's task was not lightened by the subsequent conduct of his neighbour. When Von Kluck renounced his plunge southeast he did it with such thoroughness as to lead to the transfer of practically his whole strength to the Ourcq. On Sept. 7 he demanded back the III. and IX. Corps which he had lent Von Bülow but the day before. The withdrawal of these units to the Ourcq exposed Von Bülow's right flank; a great gap was thus opened between the II. and I. Armies and Von Kluck, who had, on Sept. 5, inconvenienced Von Bülow by his undue proximity, was now seriously embarrassing that commander by his aloofness.

III. THE GERMAN RETREAT

Retreat of Von Bülow.—Generally speaking, the task of the IX. Army under Foch for Sept. 6 was to support the advance of the V. Army with its left flank while maintaining a watching attitude along the rest of its front. Foch, however, found himself quite unable to carry out even the moderate programme he had drawn up. Von Bülow was endeavouring to wheel into position between Marne and Seine, and on his left the III. Army's orders were to push due south. As a result the French were attacked with considerable vigour all along the line for, although his right was becoming compromised, Von Bülow was able on the 7th to push on with his centre and left, the latter flank working in conjunction with the German III. Army. But owing to the determined resistance of the French IX. Army under Foch and to the assistance afforded him by the French V. Army on his left, the Germans made no great impression other than to deny the French IX. Army the possibility of making progress north and west. On the following day, Sept. 8, the Germans renewed the attack and a serious position developed for the right of the French IX. Army, which was forced to give ground. Foch refused, however, to be perturbed inasmuch as the news which came in of the course of the fighting east and west of him was reassuring.

On the 9th a sudden German attack told on the French left. Foch's reply was to move his reserve from his shattered left to join in a counter attack from his right, realising as he did that the danger of the German thrust was more apparent than real.

Reports as to the forcing of the line of the Marne by British troops during Sept. 9 forced Von Bülow to the conclusion that retreat was inevitable for Von Kluck, and that his own II. Army must fall back at once, if it were to avoid envelopment on its right flank. With the object of gaining time to get his long trains safely back over the Marne, the offensive by his left and centre was carried out with vigour during the morning, the French right being driven back to Salon; but early in the afternoon the German II. Army and the right of the III. Army were in full retreat, strong rear guards being left facing the French.

Verdun.—The fighting described up to the present, *i.e.*, that between the Ourcq and Fère-Champenoise, must not be allowed to overshadow the operations of the French armies between Vitry-le-François and Verdun. For nowhere on the whole front was the tenacity of the French III. and IV. Armies surpassed. It was towards the east that the Germans hoped to retrieve their failure elsewhere. Here they hoped to cut off Verdun from either side and to bring about a kind of minor Sedan in which the French I., II., III. and IV. Armies might be herded together and destroyed. The German VI. and VII. Armies were to advance eastwards across the Moselle; the IV., with its right passing through Vitry-le-François, was to bear down across Champagne, while the German Crown Prince with his V. Army was to proceed round the entrenched camp of Verdun. Fortunately for the French the Crown Prince based his advance upon a misconception. He assumed that Verdun would be left to its fate, whereas Sarrail commanding the French III. Army kept his right attached to it throughout and, further, on his own responsibility, ordered the fortress commander to use his troops to make an attack on the Crown Prince's communications.

German Retreat.—The attacks of the Germans brought the French into a serious position, especially the IV. Army of Langle de Cary. In fact, at one time there was a serious chance that its right might be rolled up. However, reinforcements from the extreme French right, that is to say the I. and II. Armies in the Vosges, restored the situation. Then, on Sept. 8, the III. Army was called upon to deal with a new peril. Fort Troyon was in serious difficulties and thus a very patent danger to the rear of the III. Army was suddenly revealed. The garrison, however, put up a stout resistance and the place was relieved by a French cavalry division from Toul on Sept. 10. The Germans renewed their attacks on the following day but they were without significance. From Verdun to Paris five German armies were in retreat. The great battle of the Marne had been fought and won.

It was not for several years after the battle that the world learnt how and why it was broken off by the Germans. The truth is that by Sept. 8 Von Moltke had completely lost his grip of the battle. In these circumstances a liaison officer, Lt. Col. Hentsch, was directed to visit the V., IV., III., II. and I. Armies in turn and to bring back a clear idea of the situation. Further, he was empowered to issue such orders as would close the gap between the I. and II. Armies should he find that retreat had set in upon the right wing. The critical point of his tour was his visit to the II. Army where he spent the night of Sept. 8–9.

Von Bülow was considerably disconcerted about the passage of the British over the Marne; he came to the conclusion that the retreat of the I. Army was inevitable, and that therefore his own II. Army must fall back if his right were not to be enveloped. Hentsch agreed and proceeded next day to the I. Army, where he interviewed Von Kluck's chief of staff. Although the latter considered that the I. Army could hold its own there was now no option but to order its retirement. Thus by the late afternoon of the 9th the whole right and right centre of the German Army was falling back. Supreme headquarters, in ignorance of the fact, were preparing for a continuance of the offensive but had to bow to the inevitable. During the 10th orders were issued for the retreat of the five armies behind the Aisne and Vesle. By the 16th the German front was thus traced out—the neighbourhood of Noyon, the plateaux south of Vic-sur-Aisne and Soissons, the tableland of Laon, the heights north and west of Reims north of Ville-sur-Tourbe, Varennes, and thence to the Meuse near Forges wood, north of Verdun.

Conclusions.—Thus tamely petered out the grandiose German plan, and thus ended the great and decisive battle of the Marne. Tactically indeed it was somewhat of a disappointment to the Allies. No part of the German host was annihilated or even immobilised for any length of time. The number of trophies and prisoners was inconsiderable. The Germans broke off the fight in their own time. No great pursuit, as had succeeded Jena, took place, and the Germans were able to retire, if not unscathed at any rate in fair order. From the strategic and moral aspects however, the battle was of immense importance. It marked for the Allies the definite turn in the tide of defeat, while for the Germans it marked, no less, the collapse of the plan with which they had entered on the War and on which the Great General Staff had been prepared to hazard the fate of the Fatherland. That plan had aimed at securing a rapid decision in France with the bulk of the German armies, and the subsequent and immediate prosecution of a second campaign against the more slowly mobilising strength of Russia. But by Sept. 10 1914 the Germans had definitely acknowledged defeat in France. It is significant that the Battle of the Marne has been called by the Germans themselves *der Wendepunkt* (the turning point) of the War.

MARNE, SECOND BATTLE OF THE.—The second battle of the Marne developed between July 15 and Aug. 4 1918. Beginning with the German offensive of July 15, which was broken on the Champagne front between that date and July 18, it was concluded by the victorious counter-offensive of the French armies of July 18–Aug. 4, extending from the Marne to the Aisne. This was the prelude to the general offensive of the Allied Armies and their uninterrupted march to the victory of Nov. 11. A typical "defensive-offensive" battle, it demonstrated at once the will of the French high command to impose its preconceived plan upon the enemy, and the rare faculty possessed by the French soldier of passing direct from parry to riposte with an energy and vigour that recent ordeals seemed only to have strengthened. (*See* also GERMAN OFFENSIVE.)

I. INTRODUCTION

Two months earlier, Gen. Foch, Commander-in-Chief of the Allied Armies, had decided to take the initiative at the first possible moment,[1] and, true to the principle that "to make war is to attack," was determined to give the enemy no further respite once he had gripped him. The opportunity he sought was given him by a mistake on the part of the German supreme command, which, having crowded its forces into the pocket of Château-Thierry, was now to find the position made worse by the resounding check to the offensive in Champagne.

German Plans.—The Allies had had information at the beginning of July of two German plans of offensive: one on the French front in Champagne, the other on the British front from Arras to Ypres. It remained to be seen which would be launched first, for the enemy had not the necessary reserves and material for the execution of the two simultaneously on such extended fronts. It soon became known that the attack in Champagne would precede that in Flanders and would take place about July 9 or 10. As it turned out, the check to the first offensive was to prevent the enemy from executing the second. The enemy's plan was known in detail: he was to attack on either side of Reims, the principal effort being entrusted to the I. and III. German Armies, moving on Châlons, while the VII. Army crossed the Marne in the direction of Dormans and rejoined the main attack in the region of Épernay.

Foch's Preparations.—Meanwhile Foch was preparing the severe riposte that he was about to inflict on the enemy. To meet the essential requirements of the expected defensive battle in Champagne and, at the same time, to make provision for the counter-offensive which Pétain was preparing in the Soissonnais

rought together between the Oise and the Argonne a reserve ss of 38 infantry divisions (29 French, four British and five erican) and six French cavalry divisions. These strong reves were to be augmented at an early date by the arrival of American divisions, just in time for the critical moment n the adversary could only with difficulty maintain his forces. s, in the middle of July, the point was reached at which the nce between the forces became re-established and was ut to turn in the Allies' favour. This was the moment chosen Foch for taking the offensive.

omposition of French Army.—Before defining the part played the French Armies in the second battle of the Marne, it may s well to state that they comprised, at that time, 103 divisions, ded into three groups of armies under the command of Gen. ain, whose headquarters were at Provins.

egoutte with his VI. Army was later placed under the orders of olle, in the reserve group of armies. De Mitry's IX. Army was ght in during the course of the battle.

hese forces held 600 km.—this being about two-thirds of the l Allied front.

General Organisation of the Offensive.—The general-in-chief had, on July 12, stated the mission of the two groups of armies to be: "to reduce the pocket of Château-Thierry by means of two lateral thrusts towards the plateau situated north of Fère-en-Tardenois . . . ." so as to bring about the junction in this region of the two groups of armies, the tactical limits for which were clearly marked by the line Château-Thierry (for the Reserve group), Fère-en-Tardenois (for the Centre group). He had, as early as July 8, settled the means that would be at their disposal, defined the action they were to take, and ordered the preparation.

But the Centre group of armies, against whom the imminent attack would be directed, had still first to break this attack and in due course re-establish the continuity and security of its front; after which it would immediately proceed to the counter-offensive with all the means at its disposal, and Gen. Pétain exhorted "the command of every échelon to set themselves resolutely to act on the principle of simple, audacious and rapid methods of attack."

II. THE GERMAN OFFENSIVE IN CHAMPAGNE

From July 1 onward the French IV., V. and VI. Armies were on the alert and ready to receive the assault. The IV. Army (Gouraud), to the east of Reims, occupying a highly organised front, was to make a completely successful test of the new method of disposition in depth, ordered by Gen. Pétain. It had finally been decided to leave nothing along the line of outposts (constituted by the Monts de Champagne) but "islands" of resistance, which would be required to sacrifice themselves for the purpose of dissipating the enemy attack and keeping it under the well-controlled fire of the main position established in the rear. The moral preparation was on a level with the organisation of the defensive, and General Gouraud was able to address his men in such terms as these: "The bombardment will be terrible. You will stand it without flinching. The attack will be formidable, delivered in clouds of dust, smoke and gas . . . . but you will break it and it will be a great day. . . ." It was not possible to prescribe a rigorous application of the principle of defence in depth (as in the case of the IV. Army) for the V. and VI. Armies, as their defensive organisation was recent; it was to be feared that in their case the manoeuvre would develop under less favourable conditions.

On the 14th, at 8 P.M., a *coup de main* by the IV. French Corps brought in 27 prisoners, who, on being questioned, revealed the fact that the German attack was to be launched that night, the artillery preparation being timed for 12:10 A.M. But before it began, the French counter-preparation and counter-battery fire opened on the whole of the enemy front. The enemy, though stupefied by the number of our batteries, carried on according to programme, and, between 4:15 and 5:30 A.M., the German infantry advanced to the attack on a 90 km. front, from Château-Thierry to Massiges (leaving out the Reims Salient). To the east of Reims, thanks to the steps taken by Gouraud, the attack suffered a complete reverse. The enemy infantry was broken up by French artillery fire and decimated by the machine-guns distributed along the outpost line before even reaching the main line of resistance, which, in spite of repeated assaults, they failed to break at a single point. To the west of Reims the situation was less favourable.

German Success at Dormans.—In front of the V. Army (Berthelot) the enemy made some progress between the Marne and the Ardre in the direction of Épernay, and the French Centre (V. French Corps and II. Italian) was thrown back on the second position along the line Pourcy-Belval-Reuil-sur-Marne. Lastly, the right of the VI. Army (Degoutte) was not able to stop the enemy from crossing the Marne on either side of Dormans, between Jaulgonne and Verneuil. The VII. German Army thus established a bridgehead south of the river, in front of the V. Army's left and the VI. Army's right; it also regained touch with the I. German Army on the slopes of the Montagne de Reims. On this side the situation was therefore serious, and Pétain decided to check the adversary's advance by reducing first of all the pocket which had just been formed. To this end he engaged, on the 16th, practically the whole of the Allied reserves intended for the defensive battle.

The French command was now confronted with a serious problem. It was still three days to the counter-offensive, which the Reserve group of armies had orders to carry out on July 18. The question was, whether to continue the preparations for this counter-offensive and risk losing the Montagne de Reims or to suspend preparations in order to parry the immediate blow. Foch decided to maintain his plan of offensive intact, and gave orders to proceed with the preparation. The general staff of the British XXII. Corps and the 51st and 62nd Divisions were already on the move; these divisions were to appear on the field of battle of the Centre group from the 19th onward. Following them on July 17th the British 15th and 34th Divisions were to march for the neighbourhood of Pont Sainte-Maxence and of Chantilly-Senlis respectively at Foch's disposal.

German Attack Checked.—The German attack had degenerated into local actions, disconnected and therefore useless, from July 16 onward. By vigorous counter-attacks the French had even recaptured some of the enemy's *points d'appui*, while our artillery and aircraft, by bombarding the Marne crossings, made it more and more precarious for him to obtain supplies. The only progress in the attack—to the southwest of Reims between the Vesle and the Marne, on July 16—remained fruitless, for it had cost the enemy too dear for him to repeat such sacrifices.

After two days of useless efforts, therefore, the German command stopped the costly " Friedensturm " operation, on which they had based their supreme hope, and on July 17 their army was on the defensive. The third grand offensive, which the enemy had carried out with even more powerful means than the two preceding ones (44 divisions on a front of 80 km.), had failed completely. On July 18 was to be launched the French counter-offensive, in which British and American divisions were to participate. Fortune had changed sides. The operations of the Centre group of armies for the clearance of the south bank of the Marne, the recapture of Château-Thierry and the disengaging of the Paris-Avricourt railway line, formed part of the general offensive action prescribed for the two groups of armies on July 12 and initiated by the Reserve group on the 18th, under conditions which will be dealt with later.

III. COUNTER-OFFENSIVE OF THE FRENCH

The French counter-offensive comprises two phases: (1) the first extends from July 18–28, and includes the victorious battles of Fayolle's main group of armies in the Soissonnais and on the Ourcq, and the closing stage of the defensive battle of Chan pagne and Reims during the same period, in which the Centr group under Gen. Maistre re-established its front and passed to th attack. This first phase, again, comprised three successive ma noeuvres: the breaking of the enemy positions by the Reserv group of armies on July 18 and 19; the re-occupation of Châtea Thierry and the south bank of the Marne by the Centre group armies, in combination with the right of the Reserve group, c July 20 and 21; and the co-ordination by the general-in-chi of the main effort of the two groups of armies on both bank of the Ourcq in the general direction of Arcy-Sainte-Restitu and Fère-en-Tardenois on July 23 and 24. (2) The second phas sometimes called the battle of Tardenois, extends from July 2 to Aug. 4, and includes the recapture of Soissons and the pus towards the Vesle.

French Preparations for Attack.—We have seen that, actin upon Pétain's instructions of July 12, Fayolle prepared a counte offensive for the 18th, which aimed at reducing the pocket Château-Thierry. These preparations were continued with th utmost secrecy while the Centre group of armies (Gen. Maistre were checking the last enemy offensive (July 15 and 16) an (from the 17th) arranging a counter-attack. In this connectio it is interesting to take stock of the means which Maistre was t have at his disposal for passing direct from parry to riposte an those which Fayolle, for his part, was assembling in silence in th region of Villiers-Cotterets on the right flank of the enemy Marne salient.

The counter-offensive of the Centre group was entrusted t two armies, the V. and the IX., the latter having been put int the front between the V. and VI. Armies. The V. Army (Berthe lot), which had been so heavily attacked at Reims, had eigh divisions in first line (including the Italian 3rd Div.), and on infantry and two cavalry divisions in second line. Three of it divisions, among them the Italian 8th Div., had been withdraw for reconstruction. At the same time the British 51st and 62n Divs. were now being held in reserve in the Vertus-Avize zon The IX. Army (de Mitry) had five divisions, including the Ame ican 3rd Div. in first line, one division in second line, and tw reserve divisions, including the American 28th Division. Tw other divisions were in course of reconstruction. On the 17t the mission of the two armies was confirmed: they were t regain all the ground lost between Reims and the Marne and t clear the south bank of the river at the same time as the Reserv group of armies launched its attack. The reserve group operate with the X. and VI. Armies. The X. Army, under Gen. Mangi (battle headquarters at Bonneuil-en-Valois), who was responsib for the main attack, had 10 divisions in front line, including th American 1st and 2nd Divs., placed on the flanks of the Moroc can Div. in the centre of the army, and six divisions in second li and the II. Cavalry Corps, making a total of 16 infantry divi sions and three cavalry divisions. In the rear of the army th British 15th and 34th Divs. were in reserve to the east of Pon Sainte-Maxence and Senlis. In addition, the army was given large number of tanks and strong artillery reinforcement The task which Mangin set before his troops was " to brea through the enemy front between the Aisne and the Ourcq an push straight on in the direction of Fère-en-Tardenois in liais with the offensive of the VI. Army."

On his right the VI. Army, commanded by Degoutte, whos own right was engaged in the defensive battle, had only seve divisions in front line—among them the American 4th an 26th Divs. (American I. Corps at la Ferté under Jouarre) and one division in second line. The battle headquarter was at May-en-Multien. Degoutte was to attack with his ow resources only, reinforced, however, by tanks. His orders we that " the main attack would take place between the Ourc and the Rû d'Alland with the object of reaching the line Neuilly Saint-Front—rounded hill of Breuil—and eventually of develo ing the attack in the direction of Coincy in liaison with the Army towards Brény-Armentières." He had further at his di posal the British 9th brigade of the Air Division, which wa to " support his attacks."

Secrecy of Concentration.—The operations of the Reserve group of armies had been prepared with infinite precautions for maintaining secrecy—the essential factor in a surprise. The reinforcing divisions were only brought up to the front during the last two days, their movements being carried out by night, between July 14 and 16, the mounted elements marching and the unmounted carried by motor transport. No more rapid and complicated concentration had ever been carried out. Pétain had issued an order on the 17th stating the conditions of the counter-offensive for the following day, which concluded with these words: "The general-in-chief expects that the ardour and energy displayed by all will make July 18 a glorious day."

A violent storm which burst noisily during the night of the 17th–18th intensified the darkness and made movements in the woods very difficult; but it was favourable to secrecy and by 4 A.M. on the 18th the X. and VI. Armies were in position and ready to move without any sign of uneasiness being shown by the enemy. At the same hour the Centre group of armies was preparing to counter-attack. At 4:35, without a single preliminary round, the whole of the French artillery opened fire from the Aisne to the Marne, and 16 front line divisions dashed forward with the tanks, while all the air squadrons went up. In the X. Army the infanry and tanks advanced without an artillery preparation behind a rolling barrage, turning the enemy's strong defensive positions and quickly gaining a footing on the plateau northeast of the orest 'of Villers-Cotterets. In the VI. Army, on the contrary, he attacking divisions continued their artillery preparation gainst the enemy's defensive position for 1½ hours, and only ttacked at 6:05.

The surprise was complete, and, along the whole front, the nemy lost practically all his advanced units and batteries. His resistance was only effective in two localities on the broken round from Louâtre to the Buisson de Hautwison, at which oint the XI. Army Corps, having no tanks, progressed only ith difficulty and to the west of Neuilly-Saint-Front, where he II. Corps came under oblique fire from the heights of Chouy. Mangin received information of the first results achieved towards o'clock, and exploited them without delay by the judicious use f his reserves. General Robillot's Cav. Corps had experienced xtreme difficulty in debouching from the forest of Villers-otterets, which was encumbered with troops and baggage, and ould as yet operate only with dismounted squadrons—the hour the cavalry had not struck! On the first day the enemy st 12,000 prisoners and 250 guns.

The battle raged through the night of July 18–19 and throught the day of July 19. The two French armies substantially tained their objectives, even in the difficult region of Louâtre-houy-Neuilly-Saint-Front, where the XI. and II. Corps comned their attacks to subdue the enemy resistance. The artilry and air force were both definitely superior to those of the emy. The artillery pushed its batteries forward and the bombg machines attacked the Marne crossings and the enemy contrations at Oulchy-le-Château and Fère-en-Tardenois.

The Central Group Reinforced.—While Fayolle's group of mies had, by means of heavy pressure and exploitation of the rprise, penetrated deeply into the enemy's positions, the Centre oup was preparing to clear the south bank of the Marne. t its units were exhausted by the resistance they had to put against the German attacks of July 15–18, and in order reinforce them with fresh troops the British XXII. Corps 1st and 62nd Divs.) was brought in to relieve the Italian rps. Pétain took care to insist that it was not a question of a nple relief. "It will be carried out on the move—that is to y, it will take the form of a surprise attack, carried out with e co-operation of the French units on either side."

Foch defined the character that the battle was expected to ke as follows: "The battle, when engaged, will be conducted th the utmost energy and without waste of time, in order to ploit the advantage gained by surprise." Nevertheless it s not until the 20th that the Centre group was able to push ward. On that day its IX. Army reached the south bank of e Marne, evacuated by the enemy during the night, while in the V. Army the British XXII. Corps was heavily engaged in the Courton wood, where it took several hundred prisoners.

The fighting continued to be very severe throughout July 21 and 22. On the two wings of the French disposition the enemy offered a stubborn resistance to the attacks of the X. and V. Armies which pressed on their flanks. It was evident that he wished to gain time for evacuating the material and troops that he had risked towards the Marne. At last, however, on July 21, at 7 A.M., the 39th Div. of the XXXVIII. Corps, attached to the VI. Army since that morning, reoccupied Château-Thierry. The American 3rd Div. crossed the Marne in its turn, to the east of the town, and entered the Barbillon wood. In the VI. Army the American I. Corps and the French VII. and II. Corps advanced on the plateau of Etrepilly and Latilly, and on the 22nd, at noon, the VI. Army re-established its communications by way of Château-Thierry. On the same evening elements belonging to the V. Army gained a footing north of the Marne, at Port à Binson and two battalions of the IX. Army crossed the river at Passy-sur-Marne.

Capture of Butte Chalmont.—From the 22nd onward the two groups of armies exercised continuous pressure upon the enemy, the Air Division co-operating in mass in the pursuit. But the whole interest of the battle was focussed, on July 25, on the heights dominating the Ourcq valley from the north—Orme du Grand Rozoy and Butte Chalmont. Once these heights were captured, the X. Army would be able to push on the Arcy-Sainte-Restitue and the VI. Army to move on Fère-en-Tardenois, skirting the wooded region on the north side, in conformity with the plan of the French high command. On July 25 the two divisions of the French XI. Corps took by assault Oulchy-la-Ville and Oulchy-le-Château and gained a footing on the west slopes of Butte Chalmont, thus depriving the enemy of all hope of re-establishing himself on the Ourcq. The two armies[1] lost no time in following up their success, as soon as they had concentrated all their available means and relieved those units which had been most severely tried. The VI. Army was indeed able to shorten its front and rearrange its disposition accordingly. A fresh division, the American 42nd, was also added to it.

Advance Checked at Fère-en-Tardenois.—The attacks went forward on the 27th. "Forward! . . . however tired the troops!" telegraphed Fayolle, and progress continued to be made on July 27 and 28 as follows: the VI. Army reached the Ourcq and gained a foothold in Fère-en-Tardenois; the V. Army reoccupied its positions of July 15, and the divisional cavalry pushed its patrols beyond the infantry's advanced guards. But from the 28th, at noon, the VI. and V. Armies met with a stubborn resistance and a barrage that was solidly established from Fère-en-Tardenois to Ville-en-Tardenois. The II. Corps was unable to debouch from Fère. The American I. Corps, which had advanced as far as Sergy, was violently counter-attacked there by a Guards Division. The village was taken and retaken four times and finally held by the American 42nd Div., though only at the cost of heavy losses.

The advanced guards of the V. Army could debouch neither on Villers-Agron nor on Ville-en-Tardenois. In the centre, therefore, the situation remained practically unchanged on July 29 and 30. On the two wings there was fierce fighting on the 28th, on the west towards Buzancy, where the British 15th Div. gained a footing in the village and was driven out again, but succeeded in holding the park of the château; and on the east, where the enemy made repeated counter-attacks and the Allies had to fight costly engagements in order to hold their recent gains. Only the right of the X. Army made definite progress. On the 28th the XI. Corps took Butte Chalmont, and on the 29th the XXX. and XI. Corps with the British 34th Div. occupied Grand Rozoy; but the divisions in line had reached the limit of their powers after several days of incessant fighting.

First Phase of French Offensive Complete.—The enemy had made heavy sacrifices to gain solid support for his flanks and cover his line of retreat towards the Vesle. The resistance that he offered everywhere made it clear that he was not to be underestimated but was capable of violent reactions, and it now became necessary to hasten his retreat by a direct action against the plateaux of the Tardenois. The first phase of the French counter-offensive was now at an end: the Marne valley and the Paris-Avricourt railway line had been completely cleared. This was the first of the "clearance" offensives laid down in the orders of July 24, which had been issued by Foch to the commanders-in-chief of the Allied armies. The second phase was now to begin, and Fayolle's appeal to the endurance of the troops was indeed timely, in view of the severe battles that lay before them without hope of respite before the winter.

---

[1] The IX. Army had been withdrawn from the front since the 25th. The III. Army Corps had joined the V. Army.

The days of July 30 and 31 mark a pause in the progress of the French armies, which on July 29 received fresh instructions from Pétain for the combination of their attacks. The VI. Army, reinforced by the III. Corps and charged with the main action, was to "push vigorously, and without stopping, in the general direction of Fismes and Bazoches with its whole front, its left to establish itself in the region of Saponay so as to facilitate the debouching of the right wing of the X. Army towards Cramaille." The X. Army was to make every effort, by successive actions starting from its right (the south), to reach the line Bois d'Arcy, upper course of the Crise, and then by way of the Arcy-Sainte-Restitue plateau to work in the general direction of Braine. "The V. Army was to support the right wing of the VI. Army, making its effort in the direction of Romigny-Lagery-Crugny, along the heights on the south bank of the Ardre." It was to be kept in mind that the enemy, with his wings reinforced, might launch counter-attacks between the Oise and the Aisne or on the Reims salient. Considering the nature of the coming operations, it was not expected that the two cavalry corps would be used, and the commander-in-chief therefore withdrew them and moved them to the neighbourhood of Vitry-le-François and Beauvais in readiness for the two Franco-American and Franco-British offensives that were being prepared.

Redistribution of Troops.—Reliefs were effected within the armies. The VI. Army put considerable American forces into line: the 42nd and 32nd in the first line, the 4th and 28th in second line, while the 26th and 3rd were being reconstituted in the Marne valley.

In the X. Army, Mangin, convinced that he could obtain a decisive success in carrying the heights north-east of the Grand Rozoy, rested his troops on July 30 and 31 in view of this new effort. The V. Army withdrew the British XXII. Corps and replaced them by two French divisions. The VI. Army resumed its attacks on the 31st. The American 42nd Div. maintained its hold of Seringes-et-Nesles in spite of enemy counter-attacks, and the American 28th, 32nd and 4th Divs. entered Cierges and the Meunière wood. In this way the enemy's attention was drawn to the centre on the evening of the 31st, while the next morning (Aug. 1), at 4:45, the right of the X. Army attacked in its turn and, after severe fighting, occupied the whole crest that extends from L'Orme du Grand Rozoy to Saponay inclusive. On the same day the VI. Army, though it succeeded in capturing the Meunière wood, failed before Saponay on account of the extreme fatigue of its attack divisions. Its artillery gained a definite superiority of fire, however, and the air force reported numerous outbreaks of fire and explosions in the enemy's rear. Nevertheless an obstinate resistance was maintained throughout the night by the enemy.

German Retirement to the Vesle.—At dawn on Aug. 2 the three French armies found themselves facing a void. The enemy had fallen back on the Vesle, where he intended to establish himself firmly. The forward movement of the Allied divisions was preceded by advanced guards, which soon regained contact, and by evening the troops had reached the plateaux of Ambief, Mareuil-en-Dole, Dravegny and Lhery, reoccupying Soissons at 7 P.M. On the 3rd, the left of the X. Army reached the Aisne. Its right, together with the VI. and V. Armies, arrived in the immediate vicinity of the Vesle. Contact was established everywhere. All along the front the enemy artillery and machine-guns became very active. On Aug. 4 and 5 the
Allied troops lined the banks of the Vesle, the American 32
Div. entered Fismes and the advanced guards were even able
push some units north of the river at several points. But t
enemy reacted vigorously, and in view of this well-organised r
sistance Foch had to consider whether to carry on operatio
beyond the Vesle or to remain on the south side for the tin
being.

It was obvious that a passage could only be forced by a set ba
tle in great strength. At the moment, other Allied offensiv
were on the point of being launched in Picardy and Santerre
accordance with the plan made by Foch on July 24 in the mid
of the battle of the Marne. It was desirable to reserve any ava
able Allied troops to insure the success of this plan, which w
of so varied a character that the enemy, surprised by the poin
against which attacks were directed, would not have time
parry them. It was for this reason that the order was given n
to undertake any strong action north of the Vesle, but yet
keep the enemy under the impression that such an action w
in preparation, particularly on the date chosen for the Franc
British offensive, which would thus have more chance of a su
prise.

IV. RESULTS OF THE BATTLE

The second battle of the Marne was now over. After thr
weeks of bitter, vehement and uninterrupted fighting, in whi
the French armies exerted themselves at times up to the lin
of human endurance, the following results had been achieved
of great importance materially and of incalculable moral valu
The capture of 30,000 prisoners, over 500 guns, 200 trench mo
tars and 3,000 machine-guns; the shortening of the front by
km.; the restoration of the Paris-Châlons railway line and t
removal of the threat against Paris. But above all, the enen
morale was shaken while that of the Allies was strengthene
Finally, the initiative of operations had passed to the side of t
Allies, and, in addition, their numerical superiority was assur
from that time onward by the arrival of the American forces a
their inclusion in the battle, for the battle that was just finish
marked the actual entry *en bloc* of American divisions in the offe
sive battle.

It was not, could not be, a surprise to any Frenchman—a
still less to the enemy, who had had four years' experience of t
British armies—to see the four British divisions which we
fighting among the French divisions cover themselves wi
glory; but it was questionable whether the enemy had forese
that the young American divisions, going into the attack wi
their organisation only just completed and their training st
unfinished, would be able to make good both the one and t
other by their energy, dash and courage, and by the fine co
fidence and disdain of danger which is to be looked for in so gre
a nation.

It was in the height of this struggle that Foch, relying presum
bly on the results already achieved, forestalled events to so
extent in order to hasten them, and, calling together the co
manders-in-chief of the Allied armies, issued to them his famo
orders of July 24, of which it may be said that they covered t
rest of the campaign and contained the germ of victory. Amo
the so-called "clearance" offensives that he designed in or
to get possession of a base of departure for a general offensi
the one developed between the Marne and the Aisne had alrea
done what he required of it. In fact, the action of the troo
responded to the idea of the Chief with a rapidity which, so
say, emphasised the excellence of his plan and justified all hop

The battle whose scene was in the theatre of the Marne
the second time in less than four years thus marked a turn of t
tide in favour of the Allies, and, by associating British, Americ
and Italian forces with the glorious success of the French armi
formed an auspicious prelude to the general offensive. *See* VICTOR

MARRAKESH, or Morocco (*see* 17.753), the southern capi-al and largest town of Morocco, had a population of 139,874 in 921, 1,956 being Europeans. A European town outside the old ity, at the foot of the hills of Geliz and near the military camp, as founded in 1913, and has wide roads planted with trees; it joined to old Morocco by the fine Avenue de la Koutoubia. here is also a new quarter, with shops and a public garden, in he city itself, and an hotel was opened in 1924. French and ranco-Arab schools have been started. The sub-division of orocco is under a French military governor, who is in charge of he municipal services, and it has a French court, with right f appeal to the court of first instance at Casablanca. There are ood roads to Mazagan, Mogador, Safi and Casablanca, where he trade of the city is handled; and one to Fez was in course of onstruction in 1925. There is connection by narrow-gauge ilway with Casablanca and the rest of Morocco, and a stand-rd-gauge line to Casablanca was under construction in 1926.

MARRIAGE LAWS (*see* 17.753).—It is obviously impossible ere to do more than refer very briefly to the more important hanges which have taken place in the marriage laws of civilised tates since the last article on the subject was published.

I. THE BRITISH EMPIRE

Marriage Abroad.—The object of the Foreign Marriage Act 892 was to provide that all marriages celebrated abroad—in ritish possessions outside the United Kingdom as well as in oreign countries—between parties one of whom at least is a ritish subject, before a "marriage officer" in the manner rovided by the Act, should be as valid as if duly solemnised the United Kingdom. Thus a marriage duly solemnised under he Act before a British Consul in France, although void by rench law, was held valid in England (*Hay* v. *Northcote* [1900] Ch. 262). But by the Foreign Marriages Order in Council 13, where a marriage according to the local law of a foreign untry would be valid by English law, the marriage officer ust be satisfied (*a*) that both the parties are British; or (*b*) if ly one is British, that the other is not a national of the country; (*c*) if one of the parties is British and the other a national of e country, that sufficient facilities do not exist for the solemni-tion of the marriage in the foreign country in accordance with e law of that country; or (*d*) if the man is British and the oman a national of the country, that no objection will be taken the authorities of the country to the solemnisation of the arriage under the Foreign Marriage Act. From the decision the marriage officer there is a right of appeal to the Secretary State.

Further, if it appears to the marriage officer that the woman British and the man an alien he must be satisfied (*a*) that the arriage will be recognised by the law of the country to which e alien belongs; or (*b*) that some other marriage ceremony, in ldition to that under the Foreign Marriage Act, has taken ace or is about to take place and that such other ceremony is cognised by the law of the alien's country; or (*c*) that the leave the Secretary of State has been obtained. Measures have en passed to give effect to these provisions in the Bahamas, ilbert and Ellice Islands, Gold Coast, Nigeria and Sierra Leone.

Recognition of Banns, etc.—The Marriage of British Subjects acilities) Act 1915 provides for the mutual recognition of rtificates, publications of banns, or notices of marriage issued the United Kingdom, and in any part of His Majesty's domin-ns outside the United Kingdom respectively, in the case of arriages intended to be solemnised in either, between British bjects resident in either respectively. These provisions may applied to any part of the dominions where the law makes e provisions for the publication of banns, or notices for mar-ges between British subjects intended to be solemnised or ntracted in the United Kingdom, and for the recognition of certificates for marriage. Reciprocal legislation in the dominions is a condition precedent to the issue of an order in council. Such legislation has been passed by the Bahamas, Barbados, Bermuda, British Solomon Islands, Cyprus, Gambia, Gibraltar, Gilbert and Ellice Islands, Gold Coast, Grenada, Hongkong, Mauritius, New Brunswick, New Zealand, Nigeria, St. Lucia, St. Vincent, Sierra Leone, Straits Settlements, Uganda and Victoria.

By the Marriage of British Subjects (Facilities) Amendment Act 1916, however, where the marriage is to be solemnised or contracted in the dominions, and no notice of the marriage under the law in force there is required, the Act of 1915 may be applied to that part of the dominions by order in council. By special statute any marriage celebrated abroad (either in British possessions or in foreign States) and being of doubtful validity may be validated here. There are many instances of this procedure, *e.g.*, the Marriages in Japan (Validity) Act 1912.

Deceased Wife's Sister, etc.—Marriage with a deceased wife's sister has been legalised in the Falkland Islands, Fiji, Jamaica and the Leeward Islands, and also, subject to the proviso that misconduct with the sister makes the marriage void, in Nigeria, St. Lucia, St. Vincent, Straits Settlements, Trinidad and Tobago; the Union of South Africa Act of 1920 legalises such marriages in Natal and the Transvaal, and the Marriage Decree 1915 in Zanzibar.

The Deceased Brother's Widow's Marriage Act 1921 legalises the marriage of a woman with her deceased husband's brother, including the half-blood. The same freedom is accorded in British Guiana, the Isle of Man, Jamaica, Leeward Islands, the Union of South Africa and Western Australia. Legitimation by subsequent marriage is allowed in New Brunswick and British Columbia.

Divorce.—The English divorce law has been modified by the Matrimonial Causes Act 1923 under which a husband's adultery committed since July 18 1923 entitles the wife to divorce without proof of other matrimonial offences.

In New Zealand the Divorce and Matrimonial Act 1908 has been amended by the Act of 1912, which reduces to seven years the period of detention in an asylum as a ground of divorce, while the Act of 1919 provides for the custody of children by the wife of a person of enemy origin. By the Marriage Amendment Act 1920 the allegation that persons are not lawfully married or that children are illegitimate is made a punishable offence on summary conviction by a fine of £100. The Act of 1920 extends the grounds for divorce to failure to comply with a decree for restitution of conjugal rights, and grants a divorce on a petition after three years from a degree of judicial separation or separation order or deed of arrangement or separation by mutual consent. Detention in an institution for insane persons, whether situate in New Zealand or in any other part of the British Dominions, is also a ground for divorce.

In Queensland, by the Act of 1923 lunacy for a period of five years is made a ground for divorce. The Tasmanian Marriage and Divorce Act 1919 enables a husband to petition on any of the following grounds: adultery, desertion for four years, habitual drunkenness and neglect during three years, imprisonment, violent assault, lunacy. The Victorian Marriage Act 1923 amends the Marriage Act 1915, the Marriage (Maintenance) Act 1919 and the Divorce (Insanity) Act 1919. The following are grounds for divorce: wilful desertion by either for three years, habitual drunkenness of husband with lack of maintenance of, or cruelty to, the wife, and habitual drunkenness and neglect of wife, imprisonment, violent assault, adultery of husband in the conjugal residence, or coupled with circumstances or conduct of aggravation, or of a repeated act of adultery, or lunacy, and adultery by the wife.

By the Divorce and Matrimonial Causes Act 1912 of Western Australia the grounds for divorce are adultery of the wife and adultery, sodomy or bestiality of the husband, desertion by either for five years, habitual drunkenness for four years of husband and lack of support of wife, and habitual drunkenness and neglect of wife for like period, imprisonment, violent assault and lunacy. By the Divorce Amendment Act 1919 incontinence by either before marriage is added, provided the woman was pregnant at the time of the marriage. The Married Women's Protection Act 1922 repeals the Summary Jurisdiction (Married Women) Act 1896 and provides protection to a woman whose husband is guilty of cruelty to her or her children, adultery, desertion, wilful neglect to provide reasonable maintenance for her or her children. In Zanzibar a decree of 1912 regulates marriage. The Marriage (Scotland) Act 1916 provides for the joint application of the spouses for a warrant to register an irregular marriage.

II. OTHER COUNTRIES

Baltic States.—In Estonia, Latvia and Lithuania civil marriage is now compulsory.

Belgium.—Marriage between a brother-in-law and a sister-in-law, whether legitimate or illegitimate, is prohibited by the law of 1920, where the marriage which produced the relationship has been dissolved by divorce, but it is legal where the previous marriage has been dissolved by death.

Cuba.—The Spanish civil code 1889–99 has been amended by the Act of 1918, by which marriage is a civil contract, and is only legally effective if celebrated in accord with the code. Separation and divorce are established by the law of 1918. The grounds for divorce are adultery, prostituting the wife or children, grave injury by violence, words, or conviction for crime, grave crime against the wife or children, habitual drunkenness, confirmed gambling, desertion, failure of husband to maintain the home, contagious disease and mutual consent. A divorced husband is not freed from his obligations to his children.

France.—Marriage between a brother-in-law and sister-in-law, whether legitimate or illegitimate, is prohibited by the law of 1919, where the marriage which produced the relationship has been dissolved by divorce, but it is legal where the previous marriage has been dissolved by death.

Italy.—By the law of 1919 a wife may, without her husband's consent, make a gift *inter vivos*, alienate, or mortgage her real property, make a contract of loan, transfer or collect moneys, enter into a contract of guarantee, compound or appear in court with regard to these affairs, be a trader or accept a mandate.

Mexico.—By the Law of Family Relations 1917 marriage is a civil contract by which the spouses are bound by a dissoluble bond. Community of goods is abolished, subject to any settlement. The impediments to marriage are habitual drunkenness, impotence, syphilis, insanity, and any other chronic and incurable infirmity. The following are causes for divorce—adultery, attempt to prostitute the wife, or make the other commit a crime, or corrupt the children; contraction of syphilis, tuberculosis, incurable insanity or other chronic or incurable disease; unjustified desertion for six consecutive months; absence of husband for more than a year, coupled with the obligations inherent in marriage; ill-treatment; false accusation of crime; commission of crime; incorrigible drunkenness; mutual consent. Adultery of the husband is a sole ground for divorce only in certain circumstances. Upon divorce either spouse may remarry. The custody of the children is granted to the innocent spouse. All proceedings are *in camera* and on the intervention of the Attorney-General.

Norway.—By the law of 1909 a marriage may be dissolved where either spouse unknown to the other at the time of the marriage suffered from bodily defect, epilepsy, leprosy, venereal disease, mental disease, or the wife was pregnant by another man. If divorced, the woman may not remarry within 10 months from judgment or licence.

Portugal.—By decree of 1910 marriage is a civil contract and is evidenced by civil registration, and all contracts under the name of betrothal or engagement are void. Divorce may be granted for complete abandonment of the home for three years, or absence for four years or separation *de facto* during 10 consecutive years, lunacy, contagious disease, incurable disease, conviction of homicide.

Sweden.—Separation and divorce are regulated by the law of 1920. Grounds for the former are mutual consent, neglect, drunkenness or debauchery; for the latter judicial separation for one year, three years' separation, two years' absence, bigamy, adultery, venereal disease, plot against life of spouse or imprisonment.

Switzerland.—By the Swiss civil code, which came into force Jan. 1 1912, the marriage laws were made uniform throughout Switzerland. The legal status of women is raised almost to an equality with that of men. The marriageable age for women has been raised from 16 to 18 and that of men from 18 to 20, but for both sexes under 21 the consent of parents or guardians is necessary. Mentally diseased persons are incapable of marriage. The betrothal, for breach of which damages may be awarded, is followed after publication by a civil marriage. Grounds for divorce are adultery, plot against life of spouse, abuse, gross insult, crime, desertion, mental infirmity or ruin of marital relationship. The guilty spouse may not remarry within the period prescribed by the Court.

Judicial separation may be temporary or permanent. If it has lasted for three years either spouse may sue for divorce. The father of an illegitimate child may be compelled to contribute to its support until the age of 18 in proportion to his social position. The chil of a marriage which is declared null are legitimate even neither spouse contracted it in good faith.

Turkey.—The civil code of 1926 is an adaptation of the Swiss, radically changes the legal status of women, who obtain *inter* equal rights with men in divorce.

United States.—The minimum age for marriage has fixed at 15 in Missouri, 16 in Arizona, and 18 in Tenne whilst in Montana marriage between first cousins and per either of whom is feeble-minded is forbidden. In North Da marriage with a degenerate (if a woman under 45, if a ma any age) is prohibited. New York has reduced the period wi which a guilty spouse may not remarry from five to three y and Tennessee has made a ground for divorce such cruel o human treatment of the husband by the wife "as rende unsafe or improper for him to cohabit with her."

III. DOMICILE AND MARRIAGE

Desertion.—The rule was laid down in *Mesurier* v. *Mesu* (in 1895) A.C. 517 and affirmed in the House of Lords in *Advocate* v. *Jaffrey* (1921, A.C. 146) that matrimonial statu governed by the law of the domicile of the parties. Thus domicile for the time being of the spouses affords the only test of jurisdiction to dissolve the marriage. This domicil that of the husband. In *Att. Gen. for Alberta* v. *Cook* (1926 T.L.R. 317) the Judicial Committee of the Privy Council clared that under British law a wife, even when judicially s rated from her husband, still retains his domicile and car acquire a domicile of choice.

But in certain cases of desertion the wife has been permi to sue in the domicile from which the desertion took place, thus was not compelled to follow her husband to his new do cile: *Armytage* v. *Armytage* (1898 p. 178); *Ogden* v. *Ogden* (p. 46); *Statathos* v. *Statathos* (1913 p. 46); *De Montaigu* v. *Montaigu* (1913 p. 154). This undoubtedly is a departure f what has always been the rule of law and practice in G Britain and Ireland—viz.: that the wife's domicile is the band's domicile, whatever that may be. But, as Lord C said in *Lord Advocate* v. *Jaffrey*, there is no doubt authority the proposition that "the husband will not be allowed to se his own wrong as an argument for prejudicing his wife's righ This proposition has been made statutory in some of the colon By the Victorian Marriage Act 1915 "a deserted wife wh domiciled in Victoria at the time of desertion shall be deer for the purposes of this Act to have retained her Victorian do cile, notwithstanding that her husband may have since desertion acquired a foreign domicile." The Western Austra Act of 1912 and the Tasmanian Act of 1919 are to the sa effect.

India.—It was decided in *Keyes* v. *Keyes et Gray* (1921 204) that the courts in India had no jurisdiction to grant div to parties not domiciled in India, though the marriage was c brated and the parties were resident there. By the Indian vorce (Validity) Act 1921 divorce may be granted where proceedings were commenced before the Act. By the Ind Divorce Amendment Act 1926 relief is restricted to par domiciled in India.

United States.—Throughout the United States matrimo status is governed by the law of the domicile of the parties o up to a point. This point is reached when the wife separ from the husband for a just cause (*i.e.*, any act of his w would entitle her to a limited or absolute divorce) or where t agree in writing to live apart; the wife may acquire a sepa domicile and may obtain a divorce in the State of her domi In a nullity suit, since there never was identity of domicile, wife retains her own domicile. This rule obtains also in Engla

Domicile and Validity.—The general rule that a marr valid by the law of the place of celebration is valid everyw is usually subject to the condition that it is also valid by law of the nationality or domicile of the parties. In New Y State the guilty spouse, if divorced, may not remarry du the lifetime of the other but it seems that by changing his domicile he or she may remarry, and that by the general such marriage will be valid in New York. To prevent such esult, Massachusetts has passed an Act providing that if a son residing in or intending to reside in Massachusetts is bled by the law of that State from marriage, and marries in ther State, such marriage is void in Massachusetts. And if erson residing in another State is married in Massachusetts, marriage is void if it would have been void in the State re such person is domiciled. Louisiana has also passed an providing that marriages contracted between persons, one oth of whom are domiciled in Louisiana and forbidden to ry in that State, shall be deemed to be invalid, even if valid where.

ARS: *see* ASTRONOMY.

ARSEILLE (*see* 17.766) is the second largest city in France, a population of 586,341 in 1921. Housing conditions were bad, dwellings which were condemned before the World being still inhabited in 1920, and manufacturers in consence experienced considerable difficulty in procuring labour. re was an influx of workers during the War, when there considerable industrial development, largely in the provision odstuffs and in metal manufacture. Part of the harbour me a British base, and many Indian, Australian and can troops passed through, together with refugees from pe and the East; after the Armistice an American embarkacamp was established.

efore the War Marseille was extremely prosperous, but ng it trade collapsed, and there was less military activity in the western ports. A period of great difficulty in indusand shipping has since been faced. In 1923 the total of s discharged at Rouen, where little was shipped, exceeded total of discharges and shipments at Marseille, hitherto the ing French port. The figures in 1926 were still below those re-War years. During the War basins in the harbour were ened, and a new one has since been taken in hand. A ay now runs along the coast for 60 km. as far as L'Estaque. h work has been done on the Marseille-Rhône canal. A l port has been built at its opening into the Gulf of taque; land has been assigned for industrial development, industrial suburbs are arising along the bank of the canal e, protected by embankments, it runs along the coast and es the Lave by a tunnel 7,000 metres long. It is hoped improved navigation on the Rhône, and the extension of ort to include the lakes of Berre and Caronte, will bring ge influx of trade to Marseille.

ARSHALL, ALFRED (1842–1924), British economist (*see* o). In 1890 he published his *Principles of Economics* h went through many editions and was translated into a number of foreign languages. He retired from the chair litical economy at Cambridge in 1908 in order to devote elf to writing. His next volume, *Industry and Trade*, a stic study of industrial organisation, appeared in 1919, and was followed in 1923 by *Money, Credit and Commerce*. He in Cambridge on July 13 1924.

arshall may be said to have been in the lineal descent of reat English economists—Adam Smith, Ricardo and J. S. Like their chief works, his *Principles of Economics* has me a classic. It was distinguished by its profound and matic methods of analysis, and introduced a number of concepts of great importance to the science. Although years elapsed between the publication of the *Principles conomics* and that of his next two works, much that was important in them, especially in regard to the theory of y, has been transmitted orally in his lectures at Cambridge, has influenced thought both in England and in other countries. While Marshall never tried to found a school of economic doctrine, his genius for stimulating the minds of a long succession of pupils and the example of his methods of reasoning have had a profound effect upon the development of economics in England, the British Dominions and the United States. Further information on his life and writings and a detailed bibliography of his works are to be found in the *Memorials of Alfred Marshall*, edited by A. C. Pigou.

MARSHALL, THOMAS RILEY (1854–1925), American politician, was born at North Manchester, Ind., March 14 1854. He was educated at Wabash College (A.B. 1873; A.M. 1876) and was admitted to the bar in 1875. From 1876 to 1909 he practised law in Columbia City, Ind., and from 1909 to 1913 was governor of Indiana. He was nominated for vice-president on the ticket with Woodrow Wilson at the Democratic National Convention in 1912 and was elected. He was again nominated with President Wilson in 1916 and elected for the term 1917–21. For almost two years after the outbreak of the World War he urged strict neutrality, but in 1918 publicly expressed regret for this attitude. In 1919 he welcomed the King and Queen of Belgium on their visit to Washington during the illness of President Wilson. He was a strong advocate of the League of Nations, but did not favour woman suffrage. He served on the U.S. Coal Commission in 1922. He died in Washington, D.C., June 1 1925. His memoirs, *Recollections of Thomas R. Marshall*, were published posthumously in 1925.

MARX, WILHELM (1863–), German politician, was born at Cologne Jan. 15 1863. He entered the political branch of the Civil Service and became a judge. In 1899 he was elected to the Prussian Diet and in 1910 entered the German Reichstag, where he soon became prominent among the leaders of the Centre. He was elected president of the Centre party in 1921, and on Nov. 30 1923 succeeded Stresemann as chancellor of the Reich. In Aug. 1924 he took part in the Conference of London which determined the acceptance of the Dawes Plan (*see* GERMANY). In the autumn of 1924 Marx dissolved the Reichstag in the hope of getting a government majority, and after the elections retired from the post of chancellor. In Feb. 1925 he became Prussian Minister-President for a short period. After the death of Ebert he stood as candidate for the post of president of the Reich, but was defeated by Hindenburg. In Jan. 1926 he became Minister for Justice and Occupied Territories in the second Luther Cabinet and later in the same year succeeded Luther as Chancellor.

MARY (1867–), Queen Consort of England, daughter of the Duke of Teck and Mary Adelaide, daughter of Adolphus, Duke of Cambridge, seventh son of George III., was born at Kensington Palace May 26 1867, and was baptised as Victoria Mary Augusta Louise Olga Pauline Claudine Agnes. She was affianced in 1891 to Albert Edward, Duke of Clarence, eldest son of Edward VII., who died Jan. 14 1892. On July 3 1893 she married George, Duke of York, and when he succeeded to the Throne, on the death of Edward VII., was crowned with him in Westminster Abbey June 22 1911. Both as Princess of Wales and as Queen she took a prominent part in public life, showing special and well-informed interest in all that concerned the welfare of women and children. This was particularly notable at the outset of the World War, when the organisation of relief, as well as the promotion of the women's part in public service, claimed and received her constant attention. By the universal testimony of those who came into direct contact with her through those anxious years, no one showed a more practical appreciation of the problems to be solved than the Queen. In the first month of the War she inaugurated (Aug. 20) the "Queen's Work for Women Fund" to provide employment for as many as possible of the women thrown out of work by the outbreak of war. Over 70 special relief workrooms were opened, through which about 9,000 women passed before Feb. 1915; after that date, the need became less as the women were gradually absorbed into munition making and other industries. On Aug. 10 1914 the Queen also inaugurated "Queen Mary's Needlework Guild" for the purpose of "organising a collection of garments for those who will suffer on account of the War." On March 11 1921 the

Queen showed her sympathy with the higher education of women by visiting the women's colleges at Oxford and responding generously to their appeal for funds. The interest shown by the Queen in the work of the hospitals and the welfare of the nursing profession during the post-War years was especially signalised when she opened the new College of Nursing (the gift of Lord and Lady Cowdray) in London on May 31 1926, and in other ways. (*See* GEORGE V.)

MARYLAND (*see* 17.827).—The population in 1920 was 1,449,661, as compared with 1,295,346 in 1910, an increase of 11·9% as opposed to 9% in the previous decade. In 1920 the urban population (that is, residents of towns of 2,500 inhabitants or more) was 869,422, while the rural population was 580,239, or 60% urban instead of 50·8% in 1910. A part of this increase of urban population may be accounted for by the annexation of portions of Baltimore and Anne Arundel counties to Baltimore City in 1918 (*see* BALTIMORE), by which the population of Baltimore received more than the normal increase for the decade.

The population of those cities in Maryland having more than 11,000 inhabitants and the percentage of increase for the decade was as follows:—

	1920	1910	Increase Per Cent
Baltimore	733,826	558,485	31·4
Cumberland	29,837	21,829	36·6
Hagerstown	28,066	16,507	70·0
Annapolis	11,214	8,609	30·3
Frederick	11,066	10,411	6·3

The greatest percentage of increase was the 70% (11,559 in number) of Hagerstown, an important railway and manufacturing centre of the Cumberland valley.

Agriculture.—In 1910, 48,923 farms occupied 5,057,140 ac., or 79·5% of the total land area of Maryland, of which acreage 3,354,767, or 66·3%, were improved lands. The slow transition of the state from an agricultural to a manufacturing community is manifested in a comparison of these figures with those for 1920, in which year there were reported 47,908 farms, taking up 4,757,999 ac., or 74·8% of the total land area, and showing 3,136,728, or 65·9%, in improved lands. There were 1,015, or 2·1%, fewer farms in 1920 than in 1910, a decrease of 5·9% in total acreage and 6·5% in the acreage of improved land.

In the same period the value of all farm property in the state rose from $286,167,028 to $463,638,120; of the average value of a farm from $5,849 to $9,678. The total farm value in 1920 comprised $386,596,850 in lands and buildings, $28,970,020 in implements, and $48,071,250 in live stock. The average number of acres per farm decreased from 103·4 in 1910 to 99·3 in 1920. The average value per acre of all farm property in 1920 was $97.44, instead of $56.59 as in 1910, and of land alone was $54·62, instead of $32.32. Of the total number of farms, 41,699 were operated by white and 6,209 by coloured farmers, a decrease in the first class of 2%, in the second class of 2·6%.

Of domestic animals on farms in 1920, the total value was $43,784,464. The number of horses in 1924 on farms was estimated at 135,000; of mules 33,000; of milch cows 196,000; of other cattle 103,000; of sheep 96,000 and of swine 299,000. The total value of livestock had decreased to $33,686,000 in 1924, a decline due partly to a decrease in the number of horses and partly to smaller prices prevailing for some classes of animals. The total farm value of Maryland dairy products in 1919, exclusive of products consumed on the farm, was $13,407,526, as against $5,480,900 in 1909, an increase of 144·6%.

The total area in crops in 1923 was 1,934,000 ac., as opposed to 1,927,000 in 1909. The peak year was 1918, when the total area was 2,245,000 acres. The total value of field crops in 1923 was $67,560,000. The corn acreage of Maryland was 647,000 ac., in 1909 (value of crop $11,015,000), and in 1923 the acreage was 642,000, the production 25,231,000 bu., the value of the crop $20,689,000. The wheat acreage was 589,000 in 1909, 664,000 in 1919, 543,000 in 1923. In the last year 10,426,000 bu. were raised, worth about $1.00 a bushel. Hay was grown on 398,892 ac. in 1909; 662,939 in 1919; 400,000 in 1923. In the last year 4 000 tons were raised, which was about one-half less than in preceding year. In 1923, 59,000 ac. were sown in oats, prod ing 1,758,000 bu. valued at $949,000. In barley 4,000 ac. w sown producing 132,000 bu.; 17,000 ac. in rye, producing 269, bu.; 9,000 ac. in buckwheat, producing 199,000 bu.; 49,000 in Irish potatoes, producing 3,920,000 bu.; 9,000 ac. in sw potatoes, producing 1,170,000 bu.; 24,000 ac. in tobacco, p ducing 19,008,000 lb., with a value of $4,182,000.

The apple crop in 1923 amounted to 2,300,000 bu., with a va of nearly $2,000,000; the peach crop 631,000 bu., with a valu $946,000; the pear crop 374,000 bu., worth about $1.00 a bus The tomato crop was very important in 1923; 44,230 ac. w devoted to the crop, which produced 243,300 tons, worth $3,7 000. Most of the tobacco raised is exported to France and ot European countries. In 1923, 10,420 ac. devoted to strawber produced 20,840,000 qt. and Maryland excelled all other sta except Tennessee, in the total number of carloads shipped. wool crop for 1923 amounted to 467,000 pounds.

Minerals and Manufactures.—The value of the products of mines and quarries in Maryland in 1909 was $5,782,045, an 1919 $9,698,577, an increase of 67% in the decade. Of amount, bituminous coal amounted to $8,195,667, or 84· The production of granite amounted to $627,625; of slate, $6 142. In addition, considerable amounts of limestone, mar clay, asbestos and iron ore were produced. The coal minin in the western counties of Alleghany and Garrett. The iron- produced is used entirely in the manufacture of metallic pai In 1919, 5,628 persons were employed in 126 mining industr

The total value of Maryland manufactures in 1909 was $ 669,150, and in 1919 $873,944,774, a sum which placed the s 17th in the Union in value of manufactured goods. Of amount named, $677,878,492 was the product of Baltim plants alone. In the entire state, there were in 1919, 165, persons engaged in manufacturing industries and $619,606, invested in them. In the period 1914–9, the value of Maryl manufactures advanced 131·4%. The following table shows value of the products of certain industries in 1914 and 191

Products	1919	1914
Men's clothing	$72,589,000	$39,048,0
Copper, tin and sheet-iron products	40,636,000	25,491,0
Canning and preserving	30,566,000	18,029,0
Lumber and timber products	18,744,000	11,911,0
Foundry and machine products	31,581,000	10,659,0
Meat	43,228,000	17,100,0

By 1919 there had been added to this list: cars and general s construction and repairs, for steam railways, $22,837,000; pr ing and publishing, $23,835,000; fertilisers, $37,014,000. S 1914 there has been a large increase in the number of manu turing establishments and in capital invested in manufact in Baltimore, so that the 57% which in that year was the co bution of that city to the value of manufactures in the st has been increased. Outside of Baltimore, the chief manu turing centres are the western Maryland cities, Cumberland Hagerstown.

Fisheries.—A decreased output in fishery products, resul from a lack of regulation of the taking of oysters from the nat beds, having been recognised, the state created, in 1916, a servation commission. This commission was replaced by a servation dept. in 1922. In spite of the attempt of the stat increase the supply of oysters, in 1923 it had further diminis to 3,440,810 bu., as opposed to 4,967,433 bu. by April 15 1 before the close of the season. In Feb. 1925 an exhaustive in tigation proved the healthful condition of the Maryland oys

Communications.—Beginning with the passage of the "S maker, or State Aid" Act in 1904, the state entered upon a gramme of road construction, the prosecution of which has vided it with one of the best road systems of any state. In the state roads commission was created by the Legislatur construct all state roads and state-aided roads, and as the re of its activities there have been built of both classes 1,585 m

acadam, concrete and other surfaced roads on the foundations
the once privately owned turnpikes and the unmetalled con-
cting county roads.

Education and Religion.—The development of Johns Hopkins
niversity is given in that article. The small colleges of the
te, such as St. John's at Annapolis, and Western Maryland
Westminster, have been engaged in important and successful
mpaigns for the increase of their endowments. In 1920 the
gislature passed an Act merging the University of Maryland
altimore), with its schools of law and medicine, and the Mary-
d State College of Agriculture (College Park, Md.) under the
me of the University of Maryland, and under the control of
oard of regents. In secondary education, the further better-
nt of the school system throughout the state was provided
by the reorganisation of the state Board of Education by
islative enactment of 1916.

History.—A series of Acts passed since 1910 indicates a pro-
ssive quality in the administration of the state. These Acts
ated the Public Service Commission (1910), the state Indus-
al Accident Commission (1914), the Conservation Commission
16), the state Board of Prison Control (1916), the state Tax
mmission (1914), the state Roads Commission (1908) and the
rganisation of the state Board of Education (1916). In 1916
budget system was adopted, and in 1920 a merit system for
te employees was put in operation.

n 1922, largely through the efforts of Gov. Ritchie, the gov-
ment of the state was reorganised so as to consolidate and
rrange the executive and administrative departments of the
te under 19 divisions. A state purchasing agent now secures
plies for these state departments. Four great military estab-
ments were located in Maryland during the World War; the
erdeen Proving Grounds, the Edgewood Arsenal, Camp Meade
Camp Holabird. Because of their good location and con-
ience to Washington, these establishments have been re-
ned for military purposes by the War Department.

Maryland was the sixth state to ratify the prohibition amend-
nt, but never ratified the suffrage amendment. Recent gov-
ors have been: Austin L. Grothers (Dem.), 1908–12; Phillips
Goldsborough (Rep.), 1912–6; Emerson C. Harrington
m.), 1916–20; Albert C. Ritchie (Dem.), 1920–6. The latter
re-elected by a plurality of 40,400 votes in 1923. In 1924
ryland decided to cast its electoral vote for Coolidge by a
rality of 14,350.

f late, Maryland has usually been Republican on national
es, but Democratic at state elections. Through the efforts
Gov. Ritchie, a constitutional amendment was passed pro-
ing for the election of state officers at the same time as
election of national officers. This reduced the term of many
te officers then elected, from four to three years, and pro-
ed for a three-year intermission in the meeting of the Legis-
ire. Beginning with Jan. 1927 the Legislature will meet
nnially again, and the members of the two Houses will be
ted for four-year terms at the same time as the governor.

IASARYK, THOMAS GARRIGUE (1850–), first Presi-
t of Czechoslovakia, was born on March 7 1850 in the Mora-
n border-town Hodonin. His father was a coachman em-
yed on one of the Austrian Imperial estates, a native of Kop-
y in Slovakia (Slovakia then being a part of Hungary); his
ther came from a semi-Germanised Czech family of Hustopeč,
he Moravian plains. In his boyhood Masaryk was taught
ch and a smattering of German, and was educated at a Czech
ol in Čejkovice. His parents sent him for two years to the
er German Realschule of Hustopeč, with the intention of
ing him a teacher.

The object being abandoned, he became first a locksmith's apprentice in Vienna, then a blacksmith at Čejč. In 1865 his former schoolmaster induced his parents to resume their first idea of making him a teacher, and in that year Masaryk passed the entrance examination to the second grade of the "gymnasium," and began studying at Brno. He supported himself, as did many poor students, by tutoring. He developed a rebellious disposition, disagreed with some of the dogmas of the Roman Catholic Church and refused to go to confession. As a result he had to leave the gymnasium, and he continued his studies in Vienna, where he graduated first from the gymnasium with honours, then from the University, where in 1879 he became a lecturer in philosophy. He spent a year in Leipzig, where he met his future wife, Miss Charlotte Garrigue, daughter of the President of the Germania Insurance Co. of New York. In 1881 he published in German his first great sociological work, *Suicide as a Phenomenon of Modern Civilisation.* In 1882, when the University of Prague was divided into two parts, the one Czech, the other German, he was appointed to one of the Czech professorships. In 1885 he published his larger work on *Concrete Logic*, a study of the methods of classification of sciences, in which he attempted to work out a natural system of all knowledge.

In 1883 Masaryk founded a critical monthly review *The Athenaeum*, which soon sprang into prominence by becoming the battle ground on which the famous MSS. of Krláové Hradec and Zelená (Koeniginhof and Gruenberg) were attacked and proved to be forgeries, manufactured in the early 19th century by two well-meaning men, whose object was to provide text for the theory that in the Middle Ages there had been a high standard of literary culture in Bohemia. The authenticity of the MSS. had before been doubted by Slav philologists, but it was not until 1886, when Masaryk invited the great Czech philologist Gebauer to analyse the MSS. philologically, himself analysing them sociologically, that they were conclusively proved to be forgeries. The fight over the MSS. was the real beginning of the so-called "realist" revolution in Czech politics, literature and philosophy, the guiding principle of which was the application of the scientific method to letters and politics. While at Prague University Masaryk founded in 1893 a monthly review *Naše Doba* (Our Epoch). He became a member and instructor of the "Sokols." He started lecturing in Prague clubs and societies on unconventional subjects and published unpopular books. His sociological work led him to a study of Marxism, whose historical materialism he criticised in his great work *The Social Question* (1898, in Czech and in German).

Masaryk's political career started in the early 'eighties. In 1887 his friends founded a fortnightly paper *Čas* ("Time"), which two years later he took over and transformed into a political weekly. At that time the so-called Old Czech (Conservative) party was losing ground, and Masaryk, invited by the Young Czech (Liberal) party to be a candidate, was elected to Parliament in 1891. He soon resigned his seat in Parliament (1893) to devote himself to a crusade of moral education among the Czech people. He created for the Czechs what he called the philosophy of a small nation taking up the thesis of Palacky, the great Czech historian, who regarded the period of the Hussites and the Bohemian Brethren as the culminating point of Czech history, and drawing the moral that in the long traditional struggle between Slav and Teuton, which formed the main substance of Czech history, the Czech nation preserved itself by an intense love of culture and by a high standard of morality.

Although his opinions on nationalist questions were unpopular—an unpopularity which increased when in 1899 he fearlessly withstood a popular anti-Semitic superstition as manifested in the so-called "ritual murder trial" of a Jew named Hilsner—his ideas made a deep impression. They became the rallying cry of the younger generation not only of the Czechs, but of the Yugoslavs and other Slavs who flocked to Prague.

In 1900 his followers founded a political party which was officially named the "Progressive party," but which continued popularly to be known as the Realist party. The programme was founded on the principles enunciated in Masaryk's books. As a candidate of the Realist party he was re-elected to Parliament in

1907. In Parliament he soon began to criticise Austria's passive subjection to Germany and her own aggressive policy in the Balkans, especially as manifested in the annexation of Bosnia-Hercegovina. In the notorious "high treason" trial of Agram (1909), by which the Austrian Foreign Minister Count Aehrenthal tried to justify his annexation policy, and in the Friedjung trial (1909) which followed, Masaryk played a decisive part. He proved, on the basis of his private investigations, that the case for the Crown rested on documents forged at the Austro-Hungarian Legation in Belgrade. His fearless disclosures in the Austrian Reichsrat (May 1909) and in the Austro-Hungarian delegations (1910) forced the proceedings in the Agram trial to be quashed, compelled Friedjung to retract his accusations against the Serbs, and unmasked the methods of Austro-Hungarian diplomacy. Masaryk incurred the intense displeasure of the official and court circles in Vienna, but made a reputation abroad which proved useful to him during the War of 1914–8.

During the World War he developed his case against Austria-Hungary in detail, and at the end, in his work, *The New Europe*, characterised it as a corrupt, imperialist, militarist, pretentious and senseless relic of the Middle Ages. When the War broke out he was still a member of the Austrian Parliament. In Dec. 1914 he escaped from Austria, and in the following four years conducted a political and propagandist campaign in Switzerland, France, England, Italy, Russia and the United States on behalf of Czechoslovak liberation from Habsburg rule. He founded the propagandist journals *La Nation Tchèque*, which was edited in Paris by Ernest Denis, and *Československa Samostatnost* (Czechoslovak Independence), which was produced in the small town of Annemasse in Savoy, and he was one of the original Board of Dr. R. W. Seton-Watson's *The New Europe*, which was founded in London in 1916.

Masaryk's stand against Austria was publicly proclaimed in his Hus Anniversary speech made in Geneva in July 1915, and reaffirmed in his revolutionary manifesto, issued by him with the sanction of the Czech political leaders at home, on Nov. 14 1915. The signatories of that manifesto, who included representatives of Czech residents in France, Great Britain, America and Russia, formed a central revolutionary committee called the Czechoslovak National Council, of which Masaryk acted as President and Dr. E. Benes as Secretary. Finding his work in Switzerland hampered by enemy spies, he settled in London, where, at the invitation of Dr. Ronald Burrows, principal of King's College, he joined the staff of that college. Here he worked for two years combating, with the help of his friends, Mr. Wickham Steed and Dr. R. W. Seton-Watson, the German-Magyar propaganda, and familiarising Western opinion with Czechoslovak aspirations.

The Russian revolution of 1917 enabled him to go to Russia. Several thousand Czech soldiers—prisoners of war—had gone over to the Russians, and wanted to organise themselves into active military units. After some difficulty Masaryk induced the revolutionary Russian Govt. to agree to the formation and equipment of an independent Czechoslovak Army (92,000), whose exploits as they marched eastwards from Siberia to Vladivostok were one of the impressive later episodes of the War. He transferred some of them to the Western Front. He went to the United States in May 1918. The result was the Lansing declaration (May 29 1918) of sympathy with the cause of Czechoslovak and Yugoslav independence. The Allied Govts. associated themselves with that declaration on June 3 1919. The ice being thus broken, the Allied Powers and America recognised Masaryk's National Council as the *de facto* Government of the future Czechoslovak State. Masaryk was elected first President of the Czechoslovak Republic on Nov. 14 1918 and re-elected on May 27 1920. He had been sentenced to death *in contumaciam*, and in 1923 occurred the death of his wife, largely the result of the persecution to which the Government had subjected his family. For his work as President of the Republic during the years 1918 to 1926 *see* CZECHOSLOVAKIA.

Masaryk ranks equally high as a philosopher and as a statesman. His philosophical treatises were the result of his study of Czech history. His pronounced realism was a reaction both against the Teutonic idealism which developed moral specu tion without reference to the practical affairs of life and agai the Tolstoyan Slav philosophy of non-resistance to evil. Masar as philosopher, stands for a unified conception of life, in wh the spiritual and the religious take their place with the intell tual and the political as aspects of an integral whole. The lowing are the chief of his many philosophical, sociological a political works:—

O Hypnotismu, On Hypnotism (1880); *Sebevražda*, Suicide a Modern Civilisation (1881, also in German); *Theorie Pravděpod nosti a Humeova Skepse*, the Theory of Probability and Hu Scepticism (1882, German trans. 1884); *Blaise Pascal* (188 *Theorie dežin dle zásad T. H. Buckle*, the Theory of History accord to T. H. Buckle (1884); *Zakladové Konkretin Logiky*, Essay on C crete Logic (1885, German trans. 1886); *Slavjanofilism I. S. Kire skeho* (1889); *Česká Otázka*, the Czech Question (1895); *Ka Havlíček* (1896); *Otázka sociální, filosofické a sociální základy ma ismu*, The Philosophical and Sociological Foundation of Marxi (1898, also in German); *Jan Hus* (1899); *Rusko a Evropa*, Rus and Europe (1913, Eng. trans. *The Spirit of Russia*, 1919, 2 v 3rd vol. not yet finished); *The Problem of the Small Nations in European crisis* (1916); *The New Europe* (1918, French trans. 19 Czech 1919, German 1922); *Světová Revoluce* (1925, German tra 1925, Eng. trans., *The World Revolution*, 1926).

MASEFIELD, JOHN (1875–), British poet and noveli was born in Liverpool and spent his early years in many cou tries and occupations, serving before the mast at sea, and earni a living as best he could in America. The activity of these yea was reflected in his work from the first, as *Salt-Water Balla* (1902) or *Ballads* (1903), in spite of their obviously Kiplingesq inspiration, show. His early novels, *Jim Davis* (1911), *Capta Margaret* (1908) and *Multitude and Solitude* (1909), had me as tales of action and spirit, but it was in narrative poetry a drama that he found his natural expression. *The Everlasti Mercy* made something of a sensation in 1911; it was follow quickly by *The Widow in the Bye Street* (1912); *Dauber* (1913 and *The Daffodil Fields* (1913), all narrative poems in a key stern realism. Meantime Masefield had made some successf experiments in drama, with *The Tragedy of Nan* (1909) a *Pompey the Great* (1910), the first allied in subject and setting his long poems of village life, the second historical in them *Lollingdon Downs* (1917) included a noteworthy sonnet sequenc and *Reynard the Fox* (1919) proved one of the most successful his verse narratives. Later work included *Collected Poems* (1923 *A King's Daughter*, a verse tragedy (1923); *Sard Harker*, novel of adventure (1924); *The Trial of Jesus*, a play (1925 *Odtaa*, a novel (1926). He published some able prose War sketch in *Gallipoli* (1916) and *The Old Front Line* (1917).

MASON, MAX (1877–), American educationist and i ventor, was born at Madison, Wis., Oct. 26 1877. He graduat from the University of Wisconsin in 1895, continuing his studi at the University of Göttingen (Ph.D., 1903). After bei instructor in mathematics at the Massachusetts Institute Technology 1903–4, he became assistant professor of math matics at the Sheffield Scientific School, Yale University, in 19 He was appointed professor of mathematical physics at the U versity of Wisconsin in 1908. He also lectured at Harvard U versity 1911–2. During the World War he was a member of t staff of the Naval Experimental Station, New London, Con and also on the submarine committee of the National Resear Council 1917–8. He invented several devices for the detecti of submarines. In Aug. 1925 he became president of the U versity of Chicago.

MASPERO, SIR GASTON CAMILLE CHARLES (1846–1916 French Egyptologist (*see* 17.848), died in Paris June 30 191 During his second term of office as director-general of the servi of antiquities at Cairo he was made K.C.M.G. (1909). He retir in 1914.

MASSACHUSETTS (*see* 17.850).—The population in 1920 wa 3,852,356, an increase of 485,940 or 14.4% since 1910, as again

% in the preceding decade. Nearly one-third of the state's abitants lived in metropolitan Boston. Less than 1·3% were roes; 28% were foreign born, of whom 24·4% came from nada. The average density of population in 1920 was 479·2 sq. m., as against 418·8 in 1910. The urban population (in places of more than 2,500) was 94·8% of the whole, as inst 92·8% in 1910. According to a census taken by the e in 1925, the population was 4,144,205. The Census Bureau mated the population as of July 1 1926 to be 4,197,288. The ulation of the 12 chief cities was:—

Cities	1925	1920	1910	Increase % 1920–5
oston	781,529	748,060	670,585	4·5
orcester	192,242	179,754	145,986	6·9

griculture.—The total number of farms in 1925 was 33,454 ompared with 32,001 in 1920 and 36,917 in 1910. Farm perty in 1925 was valued at $293,405,059, including live k valued at $21,758,276. The average acreage of farms is easing, being 70·8 in 1925 as against 77·9 in 1920, but the rage value per acre is increasing, being $107.53 in 1925 as pared with $99.25 in 1920.

he principal crops were as follows, in bushels:—

Crops	1924	1919	1909
rn (maize)	425,780	1,921,607	2,402,738
ts	82,668	1,515,933	2,029,381
ckwheat	11,847	23,238	32,926
neat	4,028	33,253	2,404
tatoes	1,734,210	1,885,655	2,946,178
bacco (pounds)	14,058,156	14,282,589	9,549,306
e	9,947	46,261	59,183
ples	3,006,120	3,187,211	2,550,259

-thirds of the cranberry yield of the United States in recent s was raised in the bogs along the southeast coast of the state. live stock on farms in 1924 included 43,537 horses, 192,131 le (of which 145,631 were dairy cows) and 63,810 swine.

ineral Products.—During the past 15 years there was a increase in the production of building-stone, crushed rock road and street-making, and sand. The value of marble, and stone work in 1923 was $11,285,444. The value of products of the state increased from $1,647,362 in 1908 to 38,354 in 1923, of which latter amount $3,045,638 was the e of common brick. The total value of mineral products in was $15,725,000 as compared with $12,411,708 in 1920 and 77,370 in 1910.

anufactures.—Massachusetts, with a limited local market ts manufactured products, scanty resources in the form of materials, and a declining trans-Atlantic commerce, has added to its railway and terminal facilities. Only four states are ler in area: yet in 1921, only five states exceeded it in the e of its industrial output. Its advantage has lain in having rplus of capital, in its unsurpassed supply of skilled labour in the superior organisation of its factories. In its earlier lopment it utilised its local water-power, of which it had a al supply. Then it became largely dependent on coal for imported at increasingly high cost. In 1910 the total e of products of manufacturing establishments was 0,527,386; in 1921, $2,849,413,516; in 1923, $3,571,348,398. e the increase in value is largely to be accounted for by the ased prices, the state as a whole made commendable industrial progress. In textiles (cotton, worsteds and woollens), ots and shoes, boot and shoe cut stock and findings, rubber wear and in fine writing paper, Massachusetts in 1923 was oremost state.

The following table deals with the chief manufacturing industries as ascertained by the census of 1923:—

Industry	No. of establishments	Average number of wage-earners	Wages	Value of products
Cotton goods	191	113,707	$115,080,841	$415,922,838
Boots and shoes	595	69,397	82,916,416	290,674,403
Worsted goods	83	45,806	51,833,609	258,035,615
Electrical machinery and supplies	130	26,350	34,482,705	117,575,926
Foundry and machine-shop products	533	24,660	36,267,289	114,929,133
Dyeing and finishing textiles	75	14,074	16,099,333	101,824,142
Woollen goods	103	19,036	24,356,203	94,100,430

The value of boots and shoes and cut stock in 1923 was 36% of the country's output, New York ranking second with 18·9%. In 1923 the textile industries employed 33% of the manufacturing wage-earners, the products being 28% of the total industrial output. Over two-fifths of this was in cotton goods and formed 22% of the output of the whole country, North Carolina being the next largest producer of cotton goods. The output of woollen and worsted goods in 1923 was about 30% of that of the whole country, Pennsylvania producing the next largest amount. The increase in value from 1900 to 1923 was 536%. The increase in the value of boots and shoes and cut stock for the same period was 154%. Boston and Worcester were the principal centres for foundry and machine-shop products. Other industrial products were: rubber goods, $84,098,920; tanned, curried and finished leather $71,098,478, in the manufacture of which Massachusetts was second among the states; paper and wood pulp, $93,641,621; printing and publishing, $117,436,792, of which $61,326,221 was the value of newspapers and periodicals; cordage, twine and jute goods, $28,477,768, in which the state was second only to New York; furniture, $34,691,239; jewellery, $30,436,712; and confectionery, $48,618,574, in both of which Massachusetts was third among the states.

The state is also noted for its fishing industry, the fleets visiting the Newfoundland Banks being important, with Gloucester and Boston as chief centres of the trade. The value of products in 1920 was $7,596,905. Cod were valued at $2,311,011; haddock, $2,655,303; mackerel, $748,682; and halibut, $518,598.

Education.—In 1925 the total number of pupils enrolled in the public schools was 713,926, the amount expended on education being $71,941,986. In 1910 the figures were 538,441 and $17,110,327 respectively. Several fundamental changes were made in the organisation of the educational enterprises of the state in 1919. Among the most important were: the consolidation into a new department of education of several related activities, the abolition of the Board of Education, and the creation of the Advisory Board of Education, consisting of six members and the Commissioner of Education, who is *ex officio* chairman. In vocational education rapid progress occurred in the period 1909-23 the number of schools in which vocations are taught increasing from six to 80, and the enrolment in vocational classes from 1,400 to 11,870.

Another significant development was in university extension. In the year ending Nov. 30 1923, 5,075 students were receiving instruction by correspondence. In the five years ending Aug. 1923, 27,658 were registered in adult immigrant classes and 27,313 in other extension classes. In 1911 the Teachers' Registration Bureau was established, a free agency which has proved very successful; three years later a retirement system was put into operation, with membership compulsory, and provision for retirement at 60 years of age under certain conditions or by compulsion at 70. The Legislature of 1921 made several notable changes, among which are the following: Compulsory transportation from towns where there is no high school, with provisions for state reimbursement a provision compelling every town with a valuation of $1,000,000 or more to employ a school nurse, and the requirement of physical training in both elementary and high schools.

The state department may now grant the degree of Bachelor of Science in Education to any person completing a four-year course in a state normal school—one school giving it in the commercial course only, one in household arts, one in art and two in regular courses. Regular public-school teachers cannot be paid less than $750 a year. Reimbursements to small towns and cities are provided, with special arrangements for those of low valuation, enabling them to have good teachers. Civics and history are required to be taught in elementary and high schools, and since 1923, the Constitution of the United States. Pupils 14–16 years of age must have completed the requirements of the sixth grade before being certified for employment.

Finance.—The receipts of the state in 1909 were approximately $14,700,000, and those in 1923 approximately $41,000,000, or nearly three times as much. These figures represent receipts for revenue purposes only, and do not include receipts from the issue of bonds or notes. The payments in 1909 were about $17,100,000, and in 1923 about $42,507,914. These represent governmental cost and include no payments of money borrowed. In 1923 the funded debt of the state was $53,673,740, and the total debt $126,269,911.

Transportation.—There were 4,950 m. of steam railway in 1924 and 2,551 m. of electric street railway. Great attention has recently been given to the highways, and during 1924 nearly 149 m. of highway were constructed. The total length of state highways at the end of 1924 was 1,521 m.; and the amount spent on new roads in that year, about $2,000,000; repairs and maintenance, $4,798,000.

Banking.—The resources in 1923 of the national banks within the state were $1,227,367,000. There were 634 banking institutions and agents under state law, with resources of $2,488,606,935, divided as follows: 196 savings banks, $1,215,244,815; 105 trust companies, $1,076,114,436; 190 co-operative banks, $154,879,638; three savings and loan associations, $2,399,791; Massachusetts Hospital Life Insurance Co., $30,918,328; one foreign banking corporation, $1,838,749; 60 credit unions, $2,791,165; 77 steamship agents, receiving deposits of $3,187,506; one state bank, $1,132,507.

History.—During the years 1910–25 the most important laws enacted by the Legislature were the following: In 1912 a minimum-wage board was established with the right to determine wages of women and children. The inheritance law was amended so that only the real estate of a deceased non-resident is taxed, personal property taxes going to the state of residence. A law of 1913 provided for the establishment and maintenance of continuation schools and instruction for working children. A number of pure-food laws were enacted; also, a law providing for mothers' pensions. The election law was so amended that on application signed by 1,200 voters in any senatorial district, or by 200 voters in any representative district, asking for the submission to the voters of any question of instruction to Senators or Representatives, the Secretary of the Commonwealth shall determine if such a question is one of public policy, and, if so determined, he shall place such question on the official ballot to be used at the next state election. In 1914 a measure was passed submitting to the people a constitutional amendment giving suffrage to women, suffrage being finally granted June 25 1919. In 1916 the civil and criminal jurisdiction of district or municipal courts was extended so that their process runs throughout the state and makes them courts of superior and general jurisdiction. An income tax was enacted, and a law was passed to prevent misstatements in advertising. An Act forbidding the sale of narcotic drugs, except by prescriptions carefully regulated, was passed in 1917. Massachusetts on April 2 1918 ratified the Eighteenth (Prohibition) Federal Amendment, being the eleventh state to do this. That same year a budget system was adop The Legislature in 1919 made absentee voting possible for th in military or naval service and for others who made pro arrangements. It also passed a law making all Acts approved the executive, unless subject to referendum, take effect 30 d after formal enactment. Emergency laws take effect u passage. The permissible maximum amount of deposits savings banks per person was raised to $4,000. Manufactur corporations were enabled to provide for representation of th employees upon the board of directors if more than half employees so decide by secret ballot. Industrial accident co pensation was increased. The income tax was revised. An reorganising the executive and administrative functions of state Government, approved July 23 1919, established n departments, consolidated the 100 odd departments under heads, and a metropolitan district commission was authoris with general supervision over the metropolitan area. T Legislature of 1920 passed a law providing for a state constab lary. Motion-pictures within the state were censored. Wom were allowed to hold office. Suits were permitted by a against voluntary associations. Important "blue sky" leg lation was enacted. In 1921 a law was passed making a scient study of criminals mandatory on the courts in certain cas Examination is required by the Dept. of Mental Diseases, a the results are admitted as evidence of the mental conditions the accused. The opening on July 29 1914, of a canal acr Cape Cod shortened by 70 m. the distance by water from N York to Boston.

The governors for the past 15 years were: Eugene M. F (Dem.), 1911–4; Davis I. Walsh (Dem.), 1914–6; Samuel McCall (Rep.), 1916–9; Calvin D. Coolidge (Rep)., 1919– Channing H. Cox (Rep.), 1920–4; A. T. Fuller (Rep.), 1924–

(F. A. Cl.)

MASSENET, JULES ÉMILE FRÉDÉRIC (1842–1912), Fren composer (*see* 17.866), died in Paris Aug. 13 1912, having co posed an opera, *Panurge*, just before his death.

MASSEY, WILLIAM FERGUSON (1856–1925), New Zealan statesman, was born at Limavady, Co. Derry, Ireland, March 26 1856. His parents emigrated to New Zealand when was six, and eight years later he joined them at Tamaki. After elementary education, he went on the land, and 20 years lat as president of the Auckland Agricultural and Pastoral Socie began to play a prominent part in public life. He enter Parliament in 1894 as member for Waitemata, and in 19 became leader of the Conservative Opposition to Mr. Seddon a Sir Joseph Ward. At first his following was small, but he gain ground to such an extent in the elections of 1911 that in the f lowing year he was able to defeat the Mackenzie Ministry a form a Cabinet. Thereafter he played a dominating part in t Dominion's affairs. His strong personality, sterling honesty purpose and administrative ability commanded universal r spect, and during the World War, at the head of a strong Coa tion Ministry, which included his lifelong opponent, Sir Jose Ward, Mr. Massey led New Zealand with conspicuous abili and foresight. And, just as he had not hesitated to introdu conscription without reference to the people, so he had t courage, when peace came, to enforce unpopular economi He was a member of the Imperial War Cabinet in 1917–8 and 1919 was the representative of New-Zealand at the Peace Co ference in Paris. Shortly after the Imperial Conference of 19 his health gave way and though he recovered sufficiently carry on his work for a time, he died on May 10 1925.

MASSINGHAM, HENRY WILLIAM (1860–1924), Briti journalist, was born at Old Catton, Norfolk. Educated Norwich Grammar School under Dr. Augustus Jessopp, he b gan to work for *The Eastern Daily Press* at the age of seventee In 1883 he came to London and for some time was on the st of the National Press Agency. Five years later he became assis ant editor of *The Star*, which he edited from July 1890 to Ja 1891. In 1892 he joined the staff of *The Daily Chronicle* literary editor, and was editor in chief from 1895 to 1899, wh he resigned owing to his inability to support the war again

Boers. He had made his mark as an influential champion he Radical wing of the Liberal party and as the pioneer of rary criticism in the daily Press. After a brief connection *The Manchester Guardian* and *The Speaker*, and a mission South Africa in 1905 for *The Daily News*, he, in 1907, began ng association with *The Nation*, which he edited till the end 923. He was a severe critic of the World War and the Peace aty of 1919 and advocated co-operation between the Liberal- Labour parties. An early member of the Fabian Society, ssingham ultimately joined the Labour party, though on cal, rather than economic, grounds, and his last journalistic k was done for *The New Statesman*. He died at Tintagel, nwall, on Aug. 28 1924. One of the best all-round journalists is day, he was a trenchant writer on politics and a discerning c of literature and the drama. He published in 1892 *The don Daily Press*, and contributed an introduction to the norial edition of the works of Mark Rutherford 1923. *W. M. A Selection from the Writings of H. W. Massingham*, ed by H. J. Massingham (1925), contains highly appreciative mates by G. Bernard Shaw and various eminent associates.

ASSON, LOUIS CLAUDE FRÉDÉRIC (1847–1923), French orian (*see* 17.870), died in Paris Feb. 19 1923.

ASS PRODUCTION.—The term mass production is used escribe the modern method by which great quantities of a le standardised commodity are manufactured. As com- ly employed it is made to refer to the quantity produced, its primary reference is to method. In several particulars term is unsatisfactory. Mass production is not merely quan- production, for this may be had with none of the requisites ass production. Nor is it merely machine production, which may exist without any resemblance to mass production. s production is the focussing upon a manufacturing project e principles of power, accuracy, economy, system, continuity speed. The interpretation of these principles, through ies of operation and machine development and their co-ordina- is the conspicuous task of management. And the normal lt is a productive organisation that delivers in quantities a l commodity of standard material, workmanship and design inimum cost. The necessary, precedent condition of mass uction is a capacity, latent or developed, of *mass consumption*, ability to absorb large production. The two go together, in the latter may be traced the reasons for the former.

I. THE ORIGINS OF MASS PRODUCTION

origin mass production is American and recent; its earliest ble appearance falls within the first decade of the 20th ury. The mere massing of men and materials is a procedure d as the pyramids. Basic industries, like weaving, domestic ng, house construction and wooden ship building, are carried with only superficial changes, much as they were in ancient pt. Cottage manufactures and handicrafts moulded the prac- of industry until the invention of the steam-engine. With coming of power machines the seat of industry was removed the homes of the people and a new work centre, the fac- , was established. Much harsh criticism has been uttered nst "the factory system," but it is perhaps fair to say its first effect was to emancipate the home from being a adjunct to the loom or bench, and its later effect was to ide the home with means to develop the dignified status h it has now attained.

e Factory System Giving Way.—The early factory system uneconomical in all its aspects. Its beginning brought great- sk and loss of capital than had been known before, lower s and more precarious outlook for the workers, and a de- e in quality with no compensating increase in the general ly of goods. More hours, more workers, more machines did mprove conditions; every increase did but enlarge the scale llacies built into business. Mere massing of men and tools not enough; the profit motive, which dominated enterprise, not enough. There remained the scientific motive which eventually into what is called mass production.

e new method came after the failure of the mercantile and financial emphasis in manufacture. The advent and progress of financial control of industry were marked by two developments, the corporation and the labour revolt. Artificial combination of industrial plants into vast corporations for financial purposes was the first movement toward *mass* in industry. It proceeded on the theory that complete financial control would automatically bring complete profit advantage. The theory ignored many vital principles of business and its fallacy became apparent, but not before serious social hostility had been incurred.

However, it was out of the social strife thus engendered that the idea began to emerge that possibly the difficulty lay in the neglect of scientific manufacturing principles. Industry was conceded to be necessary and useful; the service it rendered was regarded as of sufficient value to afford fair compensation for all engaged in it; it was therefore urged that the attention of management should be more directly focussed on the actual labour processes that were employed. This led to what was known early in the 20th century as the "efficiency movement" with its accompaniments of time-study and similar methods, although its roots were laid in the experiences of sound industrial observers as early as 1878. It cannot be said, however, that the efficiency experts did more than direct attention to the problem, by showing, in selected instances, how the then current methods were wasteful of men's earning power, and how their correction and improvement could lead to greater production, hence higher wages, and therefore a general betterment of labour relations. They emphasised a more intelligent management of methods than was then in use; they did not see that a wholly new method was possible which would simply abolish the problems of which the old method, under the most intelligent management, was inevitably prolific. For example they dealt with methods which enabled labourers whose task was to load 12½ tons of pig-iron a day, to load 47½ long tons a day for an increase in the day's pay from $1.15 to $1.85. They did not see that another and better method might be devised which would make it unnecessary for a working-man to carry 106,400 lb. of pig-iron to earn $1.85. Mass production was not in their view, but only the alleviation of the worst errors of competitive factory practice.

The Motor Industry Leads the Way.—To the motor industry is given the credit of bringing mass production to experimental success, and by general consent the Ford Motor Co. is regarded as having pioneered in the largest development of the method under a single management and for a single purpose. It may, therefore, simplify the history of mass production and the description of its principles if the experience of this company is taken as a basis. It has been already suggested that mass production is possible only through the ability of the public to absorb large quantities of the commodity thus produced. These commodities are necessarily limited to necessities and conveniences. The greatest development of mass production methods has occurred in the production of conveniences. The automobile represents a basic and continuous convenience-transportation.

Mass production begins, then, in the conception of a public need of which the public may not as yet be conscious and proceeds on the principle that use-convenience must be matched by price-convenience. Under this principle the element of service remains uppermost; profit and expansion are trusted to emerge as consequences. As to which precedes the other, consumption or production, experiences will differ. But granted that the vision of the public need is correct, and the commodity adapted to meet it, the impulse to increased production may come in anticipation of demand, or in response to demand, but the resulting consumption is always utilised to obtain such increase of quality, or such decrease of cost, or both, as shall secure still greater use-convenience and price-convenience. As these increase, consumption increases, making possible still greater production advantages, and so on to a fulfilment that is not yet in view.

The commodities that conduce to civilised living are thus far enjoyed by only a small fraction of the world's inhabitants. The experience of the Ford Motor Co. has been that mass production precedes mass consumption and makes it possible, by reducing costs and thus permitting both greater use-convenience and price-convenience. If the production is increased, costs can be reduced. If production is increased 500%, costs may be cut

50%, and this decrease in cost, with its accompanying decrease in selling price, will probably multiply by 10 the number of people who can conveniently buy the product. This is a conservative illustration of production serving as the cause of demand instead of the effect.

II. THE PRINCIPLES OF MASS PRODUCTION

As to shop detail, the keyword to mass production is simplicity. Three plain principles underlie it: (*a*) the planned orderly progression of the commodity through the shop; (*b*) the delivery of work instead of leaving it to the workman's initiative to find it; (*c*) an analysis of operations into their constituent parts. These are distinct but not separate steps; all are involved in the first one. To plan the progress of material from the initial manufacturing operation until its emergence as a finished product involves shop planning on a large scale and the manufacture and delivery of material, tools and parts at various points along the line. To do this successfully with a progressing piece of work means a careful breaking up of the work into its "operations" in sequence. All three fundamentals are involved in the original act of planning a moving line of production.

This system is practised, not only on the final assembly line, but throughout the various arts and trades involved in the completed product. The automobile assembly line offers an impressive spectacle of hundreds of parts being quickly put together into a going vehicle, but flowing into that are other assembly lines on which each of the hundreds of parts have been fashioned. It may be far down the final assembly line that the springs, for example, appear, and they may seem to be a negligible part of the whole operation. Formerly one artisan would cut, harden, bend and build a spring. To-day the making of one leaf of a spring is an operation of apparent complexity, yet is really the ultimate reduction to simplicity of operation.

A Typical Operation Described.—For its illustrative value let us trace the course of a spring leaf after it has progressed from iron ore through ingot, bloom and billet stages, and is rolled into strips. (1) Beginning as a strip of steel prepared by the steelmill, it is placed in a punch press for cutting and piercing. The workman puts the strip into press until it hits a stop, then trips the press. The cut-off and pierced piece falls on a belt conveyor which runs along the loading end of a series of heat-treating ovens. (2) A second workman takes the pieces from belt conveyor and places them on conveyor which passes through the furnace (in which temperature is automatically controlled); thence they are deposited at a certain temperature by this conveyor at the unloading end of the furnace. (3) The heated piece is lifted with tongs by a third operator and placed in a bending machine which gives the leaf its proper curve and plunges it in oil, the temperature of which is maintained at a definite degree by apparatus beyond the operator's control. (4) As the bending machine emerges from the oil bath, the same operator takes out the leaf and sets it aside to air-cool. (5) The leaf is then drawn by a fourth operator through molten nitrate kept at a regulated temperature. (6) A fifth workman inspects it.

As a set of springs on the Ford automobile requires on an average 17 leaves, and 25,000 springs are an average day's output, this operation must be visualised as employing a great battery of lines similar to the one briefly described. As all the leaves in a spring are of different length and curve, from the bottom or master leaf to the top leaf, this operation must be visualised as one of many carried on simultaneously by different batteries of machines, each battery working on its own special size. All of these lines, with their various machines and operations, are converging on the point where the leaves are assembled into springs. The leaf whose progress we are describing is the simplest one.

We now continue the operation. (7) A sixth workman removes the leaf from the conveyor which carries it from the molten nitrate, and inserts a bolt through this and the other leaves required in the spring. (8) A seventh workman puts the nut on the bolt and tightens it. (9) An eighth workman puts on the right and left hand clips and grinds off the burrs. (10) A ninth workman inspects it. (11) He hangs the spring on a conveyor. (12) The spring passes the tenth workman, who sprays it with paint, and the conveyor carries the spring above the ovens where it was originally heated, and the radiated heat "force dries" the paint. (13) The conveyor continues to the loading dock, where the eleventh workman removes it.

One workman under the old system could attend the leaf through all these phases, or even make a complete spring, but his production would be limited. Where large quantities of the same article are to be made, the simplest operation may involve the whole time of one man: A one-minute operation will require one man a full day of eight hours to accomplish it on 480 pieces. Now this simple part, a spring leaf, must be identical in strength, finish and curve w millions of others designed to fulfil the same purpose, and t becomes a complicated and delicate procedure requiring automa machinery, the most accurate of measuring devices, pyrometer c trols, "go" and "no go" gauges—in fact, the best facilities that be provided by modern management. The leaf described, which a minor matter when compared with the whole great process, comes a major matter when considered by itself; it must have own supply of material delivered in sufficient quantities at indica places—for example, steel at 1; heat at 2; power and oil at 3; mol nitrate at 5; bolts at 7; nuts at 8; clips at 9; paint at 12. In t process the secrets of many arts and trades are employed.

The story of this minor part illustrates what is meant by orde progression of the article through the shop. It goes to meet ot parts of the motor-car which have come from other parts of plant by similar processes. The story illustrates also what is mea by delivering the work to the workman: every workman's task prepared for him by some other workman, and delivered to his ha The third principle also is illustrated—the analysis of a single into its constituent operations. The simplicity of the part h described should not be permitted to exclude from view the mu tude of other operations, ranging from the heaviest forgings to lightest manipulations in bench assembly of delicate electrical struments. Some gauge inspections involve measurements to ten-millionth part of an inch.

The economies arising from this method are obvious. The n chinery is constantly in use. It would be economically impossible maintain all this equipment for the service of men occupied in entire operation of making springs. Presses, furnaces, bending n chines, oil baths would be idle while the workman progressed fr operation to operation. Under mass production it is the work th progresses from operation to operation. Use-convenience in commodity would be lessened, while price-convenience would destroyed. Economy in machine hours is, however, only one e ment; there is also economy in time and material and labour. Ma production justifies itself only by an economy whose benefits m be transmitted to the purchaser.

III. THE EFFECTS OF MASS PRODUCTION

But it is not the history and principle of mass production whi provoke the widest discussions; the *effects* of it have been plac under scrutiny. What have been the effects of mass producti on society?

(1) Beginning with management, where unquestionably ma production methods take their rise, there is a notable increase industrial control, as distinguished from financial control. T engineer's point of view has gained the ascendancy and this tre will undoubtedly continue until finance becomes the handma instead of the mistress of productive industry. Industrial co trol has been marked by a continuous refinement of standard sation, which means the instant adoption of the better meth to the exclusion of the old, in the interests of production. Fina cial control was not, in its heyday, marked by a tendency make costly changes in the interests of the product. The eco omy of scrapping the old equipment immediately upon t invention of the better equipment was not so well understood. was engineering control, entrenched in mass production metho that brought in this new readiness to advance. In this way ma agement has been kept close to the shop and has reduced the offi to a clearing house for the shop. Managers and men have be brought into closer contact and understanding. Manufacturi has been reduced to greater singleness of purpose.

(2) The effect of mass production on the product has been to gi it the highest standard of quality ever attained in output of gre quantities. Conditions of mass production require material the best quality to pass successfully through the operatio The utmost accuracy must control all these operations. Eve part must be produced to fit at once into the design for which it made. In mass production there are no fitters. The presence fitters indicates that the parts have been produced unfit for i mediate placement in the design. In works of art and luxu this accuracy is achieved at the cost of careful handiwork. introduce hand methods of obtaining accuracy into mass pr duction would render mass production impossible with any refe ence to price-convenience. The standard quality of the produ is guaranteed by the fact that machines are so constructed th a piece of work cannot go through them unless it exactly accor with specifications. If the work goes through the tools, it mu be right. It will thus be seen that the burden of creation is

ınagement in designing and selecting the material which is to be
oduced by the multiple processes utilised in mass production.
(3) The effect of mass production on mechanical science has
en to create a wide variety of single-purpose machines which
t only group similar operations and perform them in quan-
y, but also reproduce skill of hand to a marvellous degree.
is not so much the discovery of new principles as the new com-
ıation and application of old ones that mark this development.
ıder mass production the industry of machine making has
reased out of all comparison with its previous history, and
e constant designing of new machines is a part of the produc-
e work of every great manufacturing institution.

(4) The effect of mass production on employees has been vari-
sly appraised. Whether the modern corporation is the de-
uction or salvation of arts and crafts, whether it narrows or
oadens opportunity, whether it assists or retards the personal
velopment of the worker, must be determined by observable
ts. A cardinal principle of mass production is that hard work,
the old physical sense of laborious burden-bearing, is wasteful.
e physical load is lifted off men and placed on machines. The
urrent mental load is shifted from men in production to men
designing. As to the contention that machines thus become
e masters of men, it may be said the machines have increased
n's mastery of their environment, and that a generation which
ceaselessly scrapping its machines exhibits few indications of
chanical subjection.

The need for skilled artisans and creative genius is greater
der mass production than without it. In entering the shops
the Ford Motor Co., for example, one passes through great de-
rtments of skilled mechanics who are not engaged in produc-
n, but in the construction and maintenance of the machinery
production. Details of from 5,000 to 10,000 highly skilled
isans at strategic points throughout the shops were not com-
nly witnessed in the days preceding mass production. It
been debated whether there is less or more skill as a conse-
ence of mass production. The present writer's opinion is that
re is more. The common work of the world has always been
ne by unskilled labour, but the common work of the world in
dern times is not as common as it was formerly. In almost
ry field of labour more knowledge and responsibility are re-
red than a generation or two ago.

ome Criticisms Answered.—Mass production has also been
died with reference to what has been called the monotony of
etitive work. This monotony does not exist as much in the shops
in the minds of theorists and bookish reformers. There is no
n of work without its hardness; but needless hardship has no
ce in the modern industrial scheme. Mass production lightens
k, but increases its repetitive quality. In this it is the opposite of
mediaeval ideal of craftsmanship where the artisan performed
ry operation, from the preparation of the material to its final
n. It is doubtful, however, if the mass of mediaeval toil was as
oid of monotony as has sometimes been pictured, but it is abso-
ely certain that it was less satisfactory in its results to the
ker. In well-managed modern factories the tendency to mo-
ony is combatted by frequent changes of task.

he criticism of mass production as a means of reducing employ-
nt has long since been out of court. The experience of the Ford
tor Co. is that wherever the number of men has been reduced on
nufacturing operations, more jobs have been created. A con-
ious programme of labour reduction has been paralleled by a con-
ious increase in employment. As to the effect of mass production
wages and the relations between managers and men, there is
e need to speak. It is perhaps the most widely understood fact
ut mass production that it has resulted in higher wages than any
er method of industry. The reason is at hand. The methods of
ss production enable the worker to earn more and thus to have
re. Moreover, the methods of mass production have thrown so
ch responsibility on the craftsmanship of management, that the
method of financial adjustment by reduction of wages has been
ndoned by scientific manufacturers. A business that must
nce by drafts out of the wage envelopes of its employees is not
ntifically based. It is the problem of management so to organise
duction that it will pay the public, the workmen and the concern
lf. Management that fails in any of these is poor management.
turbed labour conditions, poor wages, uncertain profits indicate
ses in management. The craftsmanship of management absorbs
energies of many thousands of men who, without mass produc-
methods, would have no creative opportunity. Here the mod-
method broadens instead of narrows individual opportunity.

(5) As to the effects of mass production on society, the increasing supply of human needs and the development of new standards of living are the elements to be estimated. The enlargement of leisure, the increase of human contacts, the extension of individual range, are all the result of mass production in various fields. (H. F.)

MASTERS, EDGAR LEE (1868–), American writer, was born at Garnett, Kan., Aug. 23 1868. At the age of 21 he entered Knox College, Galesburg, Ill., but left after one year to read law. He was admitted to the bar in 1891 and practised thereafter in Chicago, being for some years associated with Clarence S. Darrow. The book that first brought him public notice was *Spoon River Anthology* (1915), an extraordinary collection of epitaphs on members, in all walks of life, of a midwestern town. Within three years 50,000 copies were sold.

His other works include: *The New Star Chamber, and Other Essays* (1904); *Blood of the Prophets* (1905); *The Great Valley* (1916); *Toward the Gulf* (1918); *Starved Rock* (1919); *Domesday Book* (1920); *The Open Sea* (1921); besides several plays, *Maximilian* (1902); *Althea* (1907); *The Trifler* (1908); *The Locket* (1910); and *The Bread of Idleness* (1911).

MASURIAN LAKES, BATTLES OF THE.—The terrain of East Prussia is described in some detail under the heading TANNENBERG. It was the lake barrier which had proved the undoing of the Russians in their advance into East Prussia, and twice again was it to bring about their defeat when the Germans in their turn assumed the offensive. Jilinsky had failed to combine the action of his two armies, urging one forward to intercept what he thought to be a beaten enemy and dispatching the other on a subsidiary objective. The disaster to the II. Army had come to him as a crushing surprise, and in his fear that Rennenkampf would share the fate of Samsonov, he ordered the I. Army to halt and act on the defensive until fresh troops could be brought up from the centre of Russia. All chance of catching the Germans at a disadvantage during their temporary disorganisation after the fighting at Tannenberg was thus lost.

I. THE SUMMER BATTLE

Ludendorff was not long in deciding what was to be done after the destruction of Samsonov. Even before the fighting at Tannenberg was over, on Aug. 29 1914, he had commenced moving troops northwards to meet Rennenkampf. He was strongly urged to move southwards to the support of the sorely tried Austrians, but this would have meant leaving a strong and undefeated enemy directly in his rear, whilst attempting to traverse the self-same desert area which had tried Samsonov so greatly. From the German point of view it was more important to free East Prussia from the invader at once, and the Austrians must therefore wait their turn.

Position before the Action.—All the German divisions had received their first reinforcements and were flushed with victory and full confidence in their leaders. Two fresh corps had arrived from the west. Rennenkampf did not appear to be on the move and was evidently commencing the blockade of Königsberg. Lötzen, the little fortress holding the main gap in the centre of the line of lakes, was still in German hands. Everything therefore seemed favourable for a German offensive.

Ludendorff's plan for his advance was in outline as follows: (1) Von der Goltz with 2½ divisions was to check any advance on the part of the Russian II. Army from Poland; (2) Von François with three divisions and a cavalry brigade was to move round the southern end of the lakes at Johannisburg with the primary object of turning Rennenkampf's left, and at the same time dealing with any Russian forces assembling to the south of the lakes; (3) Von Mackensen with two divisions and two cavalry divisions was to cross the Lötzen gap and join with Von François in the attack against Rennenkampf's left; (4) the main body of eight divisions was to move direct on the Insterburg gap; (5) the Königsberg garrison was to make a demonstration against the blockading troops.

Rennenkampf had commenced withdrawing on Aug. 30, and on Sept. 2 he issued orders for a position to be taken up for defensive action from the sea near Libau to Angerburg at the northern end of the lakes. This position offered many advantages from a defensive point of view, running as it did behind the rivers Deime, Alle and Omet, but it was too extensive for the force of 12 divisions which Rennenkampf had at his disposal, the distance from flank to flank being 60 miles. Moreover, the left flank was exposed to attacks coming from the Lötzen gap and the southern end of the lakes. But it was chiefly in the manner in which he proceeded to occupy this position that he erred. He had no idea where the Germans were or what they had been doing in the interval since Tannenberg. He only had persistent rumours that the Germans were sending billeting parties to Königsberg. Instead of maintaining strong forces in front of his chosen position, in order to discover the enemy's intentions, Rennenkampf committed his troops at once to a linear defence of the line. He placed four of his divisions along the Deime on a front of 18 m., while keeping seven divisions to hold the remainder of his line of 42 miles. A single division was placed opposite the Lötzen gap to the east of the lakes.

It will thus be seen that from the very start of their manoeuvre the Germans had succeeded in out-generalling Rennenkampf. On the left of their line they were containing four Russian divisions with garrison troops, equivalent to about a division. In the centre they were opposing eight divisions to seven Russian divisions. On the right they were advancing with no less than five divisions and two cavalry divisions against a single Russian division.

German Attack.—Von der Goltz attacked and took Mława on Sept. 4, and thereafter kept in check any of the units of the Russian II. Army which attempted to advance. By the night of Sept. 5 Von François was approaching the southern end of the lakes. By the 6th he had taken Johannisburg and Nikolaiken, driving back the few Russian troops opposing him. By the 7th he was through the lakes and had captured Bialla and Arys. The Russian troops opposing him had been hurried up without proper artillery support and were dispersed in disorder. Eleven Russian battalions were thus dissipated without result. On the 8th Von François turned northwards against the Russian flank. Sept. 9 was to be a fateful day for the Germans. Von Mackensen had commenced his crossing at Lötzen during the 8th, but he could not enlarge the bridge-head. His troops attacked at 5 A.M., 12 noon and 8 P.M. on this day without success and that evening he reported no progress to Von François.

Von François' attack against Soltmahnen on the morning of the 9th came as a complete surprise to the left flank of the Russians opposing Von Mackensen. By noon the Russians were in hopeless rout, leaving 5,000 prisoners and 60 guns in the hands of Von François. The German enveloping movement had met with complete success. Rennenkampf's left flank division had been destroyed and about 8,000 men of the Russian X. Army concentrating about Augustówo and Osowiec had been placed out of action. The left flank of Rennenkampf's army now lay open to the attack of five German divisions. A second Tannenberg seemed more than probable.

Ludendorff had employed the 5th, 6th and 7th in bringing his eight divisions in line facing the Insterburg gap and, on the 8th, contact was gained with Rennenkampf's outposts. On the 9th, coinciding with Von François' attack, the Germans moved forward along the whole front. Little progress was made anywhere, and on the right the Russians made a determined counter-attack which completely held up the German advance. This check seems to have paralysed Ludendorff temporarily, for he ordered his right under Von François and Von Mackensen to hold fast and even to close in to the centre for fear of disaster. But Rennenkampf had taken fright at the menace to his left and had decided to withdraw. That night he ordered a general retreat. He had been just too quick for the Germans. When Ludendorff allowed his right to move forward again, nothing further than cutting off the streams of disorganised transport and breaking up the Russian rear-guards was possible. Rennenkampf had pushed his retreat with desperation. Two of his corps had covered 58 m. in 60 hours. By the 13th he was safe from annihilation, and by the 14th his exhausted troops had crossed the East Prussian frontier between the forest of Rominten and the river Niemen.

Results of the Battle.—Although the Russian I. Army had not been surrounded, it had suffered almost as much as the II. Army. Casualties since Sept. 6. had amounted to 125,000 men and 150 guns. Two corps had been destroyed and the whole army was out of action as a mobile force through lack of transport. The chief credit for this success must lie with Von François. In his march round the southern end of the lakes his men had covered 77 m. in the four critical days Sept. 6–9, and there had been severe fighting on two of those days. Had Ludendorff been quicker to realise that Rennenkampf's counter-attack on the 9th was made in order to disengage himself, and had his orders to Von François for the 10th and 11th not been so cautious, there can be no doubt that Rennenkampf's army would have been all but destroyed.

II. THE WINTER BATTLE

During their 28 days' invasion of East Prussia the Russ had lost some 310,000 men from the flower of their army and guns. Their offensive had been completely defeated and t had been thrown on the defensive. It was not till late in winter of 1914–5 that they began to show signs of activity more. From the German point of view it was importan prevent another Russian invasion of East Prussia and it therefore decided to upset by a strong offensive any Rus plans that were in existence.

German Dispositions.—In Jan. 1915 the German VIII. Ar under Von Below, was holding a line from the frontier south of Spirding, along the line of lakes to Angerburg, and thence a the Insterburg gap between Insterburg and Gumbinnen to the Memel. Some 100,000 Germans, for the most part of the Landw and Landsturm, were facing 200,000 men of the Russian X. A under Siewers. To the south there were indications of a Russian Army being assembled between Modlin (Nowo Georgiewisk) Thorn (Toruń). Four fresh corps had been allotted for the offens making a total of some 250,000 men. In outline the German was as follows: (1) The X. Army (eight divisions and one cava division, under Von Eichhorn, was to envelop the Russian ri moving southwards from the Insterburg gap. (2) The right of the VIII. Army (three divisions), under Von Litzmann, was to velop the Russian left by moving round the southern end of lakes. (3) The remainder of the VIII. Army (four divisions) wa hold the enemy in the centre.

Orders for the advance were issued on Jan. 28. The attack in south was to commence on Feb. 7, with a view to drawing the att tion of the Russians to this quarter. The main attack was ther come from the north on the 8th. Conditions were very differ from those of the advance in Sept. of the year before. The weat was bitterly cold and the whole country was deep in snow. La numbers of sleighs had been collected and the scale of clothing food greatly increased. The German administration left noth undone which could be thought out beforehand.

German Line Advanced.—Von Litzmann's advance found marshy country in front of Johannisburg almost impassal and the attack of the 7th came to little. Many of the units to force their way through blinding snow storms, and it was till the 8th that the Russian positions on the Pisseck were reach and taken, and by the 9th the end of the lakes was passed. T diversion served its purpose well, for the attack of the Germ X. Army in the north came as a complete surprise to the Russi in their winter quarters, leisurely thinking of an advance in spring. They were given no time in which to readjust their li and reserves had to be thrown in piece-meal to save the situati On the 10th, a determined stand was made by four Russ divisions on either side of Eydtkuhnen, but by evening th resistance had been broken. Everywhere the effect of the Germ heavy artillery was decisive. Despite the difficulty of bring forward the heavy wheeled vehicles, which broke through frozen crust of the ground, the Germans never failed to supp their infantry at the decisive point. By the 12th, Von Belo army had reached a line stretching from the forest of Romint to Ludwinow.

Meanwhile, the German centre had moved forward to keep touch with the southern wing. Russian resistance in the sou seemed to centre round the town of Lyck, and Litzmann reinforced by a fourth division for its capture. From the 1 to the 13th the fighting round Lyck was desperate. Often opposing sides could not distinguish each other in the blizza which swept over them, and owing to the difficulty of ammuniti supply the infantry were unsupported by artillery fire of a sort, and fierce hand to hand fighting ensued. Casualities both sides were therefore heavy and the Russians also lost o 8,000 prisoners and 14 guns. By the night of the 13th Russians had been forced from their positions and the to was in German hands.

Position after the Battle.—By the 14th, the German line from Rajgród in the south, through Suwalki, to Sztabinki in north, in a semi-circle round Augustówo, at a distance of fron to 10 m., from the town. The wooded and close nature of country made concerted attacks very difficult, but everywh the superior individual training of the German soldier triumph over the more ignorant Russian. The Russians fought w speration to maintain their positions and it was not till the th that Siewers finally gave the order to abandon Augustówo. e succeeded in escaping envelopment by abandoning most of s transport and ammunition columns and retiring in disorder on rodno. By the 20th the Germans were no longer in touch with e retreating Russians.

In the winter battle the Russians lost 110,000 prisoners and o guns, and the X. Army, like the Russian I. and II. Armies, s placed *hors de combat* for several months as a mobile force. neir defeat was certainly greatly due to the superior leadership the Germans, for they had been caught unawares in winter arters, without proper protection and with an inferior inligence service. Had the Germans been able to bring up the ole of their guns and ammunition on Feb. 14 they might have cceeded in surrounding Augustówo, but this the weather prented them from achieving.

MATERIALS: *see* RAW MATERIALS.

MATERIALS, STRENGTH OF (*see* 25.1007; also CRYSTALGRAPHY; METALLOGRAPHY; METALLURGY; METALS, FATIGUE TESTING MACHINERY).—The present article only attempts describe some of the more important advances which have n made since 1910, and to indicate the trend of modern work.

athematical Analysis of Complex Stress Systems: Stresses in s.—In the Eleventh Edition it was stated that when a bar ubjected to a simple pull applied axially—that is to say, so t the resultant stress passes through the centre of gravity very cross-section—the stress may be taken, under ordinary ditions, as (sensibly) uniformly distributed over any section near a place where the form of the cross-section changes. design of a tie of specified material to withstand a specified l is thus, as regards the greater part of its length, an easy ter; but it is essential that suitable forms of end attachment levised, equally able to withstand the imposed load.

he most usual method of connection is by pins or rivets, rted through the tie in such a way as to operate in virtue heir resistance to "shear"; and in consequence the problem tress-distribution in the neighbourhood of holes has received h attention. C. E. Inglis[1] has obtained a mathematical tion appropriate to a single elliptical hole, and the special of a circular hole has also been treated by K. Suyehiro.[2] more difficult problem of stress-distribution in an "eye " has been attacked by E. G. Coker[3] with the aid of transnt models of xylonite and the use of polarised light. Fairly plete information is thus available regarding the distribuof stress in tension members, so long as the elastic limit of material is nowhere exceeded; but a problem of greater tical importance is to proportion the eye ends so that their *king load* (after ductility has operated to equalise the stresses) be equal to that of the main portion of the tie. This lem has been attacked experimentally by W. A. Scoble,[4] has interpreted his results in terms of practical rules for gn.

rength of Straight Members in Compression (*Struts*).— tion was made in 25.1022 of Euler's investigation of the psing load of an ideal strut, perfectly straight and uniform, centrally loaded; also of a semi-empirical formula which been proposed, to allow for the fact that a short strut may by simple crushing. Since 1910 considerable progress has made in the theory of this and of allied problems. It was gnised by T. von Kármán[5] and (later, but independently) . V. Southwell[6] that crushing of the material is not the alternative to collapse by buckling under stresses within the elastic limit, because plastic distortion may bring about conditions of instability under stresses which are far below the compressive strength of the material, and which Euler's analysis also would indicate to be perfectly safe. An interesting extension of mathematical theory was made by the authors cited, in a formula which modified Euler's result to allow for the new conditions; and the experimental work of A. Robertson[7] has shown that this formula agrees closely with actual results. The whole subject of strut failure, and advances in theory and experiment, have been reviewed by R. V. Southwell.[8]

Collapse of Tubes by External Pressure.—A similar possibility of collapse exists when a circular tube (such as the flue of a steam boiler) has to withstand fluid pressure imposed upon its *external* surface. Distortion of the circular cross-section into an oval form, whilst it involves an increase in the strain energy due to bending, also involves a decrease in the potential energy of the applied pressures; the circular form will thus be unstable when the pressures are sufficiently high.

This phenomenon was investigated experimentally by W. Fairbairn as early as 1858,[9] and has attracted much attention since; an extensive bibliography was compiled by G. Cook for the British Association in 1913.[10] Recent experiments by A. P. Carman,[11] R. T. Stewart,[12] and G. Cook[13] afford satisfactory confirmation of G. H. Bryan's theoretical formula for long tubes[14] and of a more general formula proposed by R. V. Southwell,[15] who investigated the influence of end constraints upon the resistance to collapse.

Other Problems of Elastic Stability.—The general theory of these problems of "elastic stability" has been developed by G. H. Bryan,[16] R. V. Southwell[17] and W. R. Dean.[18] Among other examples of the class may be noticed the collapse of thin tubular struts, in which instability makes its appearance by wrinkling of the tube wall, and of flat plating under forces which involve compression in its own plane. The strength of tubular struts acquires great practical importance in aircraft construction, and has received much attention both in theory and experiment; bibliographies relating to these two aspects may be found in papers by R. V. Southwell[19] and A. Robertson.[20] The stability of flat plating has importance for the design of deep plate girders, and has been studied from this aspect, theoretically by G. H. Bryan[21] and S. P. Timoshenko,[22] and experimentally by W. E. Lilly[23] and others; two special cases—the stability of a long flat strip under uniform shearing actions in its plane (theoretically treated by R. V. Southwell and S. W. Skan[24]) and of a circular disk under forces which tend to twist it in its plane (theoretically treated by W. R. Dean[25]) have recently been made the basis of a suitable "acceptance test" for the thin sheet steel used in the construction of metal aircraft.[26]

"*Whirling*" *and Vibration of Shafting.*—Elastic instability is also likely to occur in a long rotating shaft, because any curva-

ture of the axis will be intensified by centrifugal force, which may be sufficient to overcome the restoring effect of the flexural stresses. When this happens, the shaft is said to "whirl." The calculation of "whirling speeds" is evidently a matter of great practical importance (since it would be unsafe to allow a shaft to run at these speeds for any length of time), and various methods have been propounded.[27] Torsion or end thrust, acting upon the shaft, will combine with rotation to promote instability; a theoretical discussion of the problem, taking all three actions into account, has been given by R. V. Southwell and B. S. Gough.[28]

It can be shown that the whirling speeds of a shaft are identical with the frequencies of its free transverse vibrations in the absence of rotation; as the speed increases, these "natural frequencies" decrease, becoming zero at the whirling speeds. The difficult question of stability in the immediate neighbourhood of the whirling speeds has been examined by F. B. Pidduck.[29]

Other Problems of Vibration.—The influence of rotation upon the natural frequencies of free vibration has been examined in two other cases of practical importance: (1) the vibrations of a rotating rod (such as an airscrew blade) have been studied theoretically by R. V. Southwell and B. S. Gough,[30] and experimentally by A. Fage[31]; (2) the vibrations of a spinning disk (representative of the rotor of a steam turbine) have been investigated by H. Lamb and R. V. Southwell.[32]

A problem of greater complexity is presented by the vibrations of a railway bridge under the periodic forces imposed upon it by the "hammer-blow" (the effect of the eccentric weights employed to balance the reciprocating masses) of a locomotive as it passes. The period of these forces may synchronise with the natural period of the bridge, and considerable deflection is then produced; but account has to be taken of the fact that only a few blows are delivered during the transit, so that the problem is not one of "resonance" in the ordinary sense. A formal solution of the idealised problem (in which the bridge is taken to be a uniform girder, and a single travelling load is assumed) has been given by S. P. Timoshenko,[33] and an elaborate investigation of cases representative of practical conditions by C. E. Inglis.[34]

Approximate Methods of Stress Calculation.—A general tendency of the period now under review has been towards the development of approximate methods of solution for problems which cannot be treated by exact theory. The original impetus came from Lord Rayleigh, in relation to the calculation of natural frequencies of vibration;[35] but his methods have since been extended to a wide range of problems.[36]

"Experimental" methods of solution have also been developed, based on analogies obtaining between the equations of elasticity and those of other branches of physics. Thus the deflection of a membrane of uniform tension is governed by equations identical with those which define the distortion of cross-sections in a twisted prism; and this fact[37] has been utilised by G. I. Taylor and A. A. Griffith,[38] who have shown how to solve, by measurements made on a flat soap-bubble, Saint Venant's problem of torsion[39] for shapes of cross-section which are mathematically intractable.

Photo-elastic Methods.—Important advances in the solution
two-dimensional systems of stress have been made by the use
"photo-elastic" methods. Various transparent materials un
the action of stress possess double refracting properties—th
is, they split up plane polarised light into two rays. The int
ference obtained by the recombination of such rays produ
colour bands which may be viewed on a screen or photographe
the colour varies according to the difference of the princi
stresses, and the stress-difference at any place in the mater
may be estimated by matching it with the colour produced
a tension piece strained by a known and uniform stress. T
sum of the principal stresses may be deduced from measu
ments of the lateral contraction of the specimen. By th
methods, E. G. Coker, L. N. G. Filon, W. A. Scoble and A.
Low have determined the distribution of stress in many ca
intractable mathematically, which possess great practical imp
tance.[40] The "stress-optical" properties of xylonite have be
studied from this aspect by Coker and K. C. Chakko,[41] and t
underlying principles of the method have been critically
amined by Filon.[42]

Extension of Theory to Problems of Plastic Distortion.—So
general interest attaches to the formula, mentioned abo
which extended Euler's analysis for elastic struts to cases
which elastic break-down precedes collapse, since this appe
to be the earliest application of mathematical theory to mater
in the plastic state. The study of plastic distortion (*i.e.*,
tortion which does not disappear when the load is remove
and its representation by mathematical equations, have attrac
much attention among continental workers; reference may
made to the proceedings of a special conference on this subje
held at Prague in 1924.

Limitations of Mathematical Theory, as applied to the Ela
Failure and Fatigue of Metals.—Such methods of representat
have this feature in common with the older theory of elastici
that they presuppose the quality of *continuity* in the id
material with which they deal. Employment of differen
equations and the methods of the calculus are not strictly leg
mate unless the properties of the material can be assumed
be unaffected by subdivision carried to any extent. Now
ordinary materials of construction are known, from microscop
examination, to be crystalline aggregates of great complex
if subdivision were carried far enough, we should be left w
fragments consisting of single crystals, and therefore hav
properties certainly aeolotropic, and probably non-elastic. T
the classical theory of elasticity, as applied to actual materi
must be regarded merely as a method of statistical treatme
valid only to the extent that actual materials may be taken
be "statistically isotropic,"[43] and it would seem that the m
recent extensions to the plastic state must have the sa
restricted interpretation. The foregoing considerations serve
explain why theory has given good results when applied to pr
lems of elastic stability or of vibrations (where the result depe
upon the general distortion of the whole body), but has
been so successful in its application to questions of elastic fail
or fatigue. Suggested criteria of yielding under compound st
(such as those of Rankine, Saint Venant, Guest and Haig
which involve the principal stresses as calculated by the ordin
mathematical theory cannot be expected to provide an ultim
explanation of occurrences which must depend largely upon
actual microstructure of the material at the point considere

Modern Tendencies in the Study of Elastic Failure and
Fatigue.—The outlook of earlier investigators, which tacitly
supposed a degree of continuity, in actual materials, compar

ith that of the ideal material of elastic theory, has been modified y increasing knowledge of the inner structure of metals, as evealed by microscopical study at the hands of Sorby, Ewing, osenhain, Humphrey, Beilby, Osmond and Arnold. In all the rdinary tests of material for engineering purposes, in the assical "stress-strain diagrams" of Eaton Hodgkinson and hers, even in the notions of the "yield point" and of "ductility," we see a general tendency to analyse *resultant* effects, oserved in a specimen of considerable size, as though these ere due to *continuous* strains (the word is used in the mathe-atical sense) in a structureless material. Even in the work of auschinger, Muir and others, who investigated the phenomenon "recovery" under prolonged rest or gentle heating, there is othing which demands a mental picture of the inner mechanism which the results are produced; and the extent to which e older ideas suffice for explaining the behaviour of materials om an engineering standpoint is shown by C. F. Jenkin's ccessful derivation of all the ordinary phenomena of low-eed tests from a conceptual "model" characterised merely a resistance to distortion due in part to elastic resistance d in part to "solid friction."[45] But to explain the first occur-nce of elastic failure, and the circumstances which attend the enomena of fatigue and ultimate fracture, it is becoming creasingly evident that attention must be concentrated upon e actual structure of the crystalline aggregate.

Thus, A. A. Griffith[46] has been led, by discrepancies found to st between theory and experiment in regard to stress-concen-tion in the neighbourhood of scratches and flaws, to propound heory of rupture, for brittle materials, which takes account the surface energy generated in the formation of cavities or cks; and he has verified the consequences of his theory by oducing fibres of fused silica exhibiting strength of a quite normal order. Attention is now concentrated upon ductile terials such as soft iron, copper and aluminium, which are gregates of small crystals arranged, in general, with random entation. The methods of X-ray analysis developed by W. H. W. L. Bragg have provided a powerful means of investigat- the structure of the individual crystal,[47] and the discovery, H. C. Carpenter, C. F. Elam[48] and others, of methods whereby gle crystals of aluminium and other metals can be produced izes such that they may be subjected to ordinary engineering s, has led, at the hands of G. I. Taylor and C. F. Elam[49] others to more exact understanding of the way in which h crystals distort under static or alternating loads.

he stress which a single crystal of aluminium can withstand hout suffering permanent distortion is markedly low as com-ed with the strength of the crystalline aggregate, and it thus ears that we must look to the crystal boundaries (where atoms presumably have a more random distribution, owing he conflicting requirements of the adjoining crystal lattices) an explanation of the relatively high resistance which the egate can oppose. This view is supported by the increased ngth which accompanies a reduction in the size of individual tals, under the influence of hardening processes such as heat tment or "cold work." It is, of course, in agreement with concept of the "amorphous phase" propounded by Ewing, enhain and Beilby (*see* 25.1018); but it remains for further stigation, using the more powerful methods which are now lable, to give precision to ideas which have proved so ul in the past, for correlating the manifold phenomena lastic distortion and fatigue. Ultimately, of course, static ning and fatigue must be explained on some common basis METALS, FATIGUE OF).

ngineering Tests.—Rosenhain's theory of "lattice distor-" propounded in his May lecture to the Institute of Metals 923 as an explanation of the hardening effects of alloys, exemplifies the new outlook which has been made possible by the discoveries since 1910; it is to microscopical, chemical and X-ray investigations that engineers are looking for a solution of the ultimate problems of fatigue. But understanding of the properties of materials is only one side of the problem of engineering design, and it is unlikely that the practical rule, that the working stress must be kept within the elastic limit, will lose its validity. The other side of the problem is stress-calculation, and stresses, in the crystalline aggregate, can only be determined in statistical fashion. So the older tests, on specimens large in comparison with the crystal structure, have not ceased to be useful, or reached the limit of their development.

A full account of experimental results will be found in R. G. Batson and J. H. Hyde's *Mechanical Testing* (1922). Considerable attention has been directed to the improvement of experimental technique and of the interpretation of results: thus W. E. Dalby[50] has introduced an improved type of specimen and a calibrated weigh-bar for the measurement of loads; A. Robertson and G. Cook,[51] by means of special apparatus designed to eliminate the effects of inertia in the testing machine, have shown that the observed inflection of "autographic" records at the "yield point" of ductile materials (*see* 25.1014) really masks a *reduction* of stress, which in some metals may be as great as one-third of the stress at which yield commences; T. E. Stanton and R. G. Batson[52] have done much to systematise the results of "impact tests"; B. P. Haigh[53] has developed an electrical machine whereby a sinusoidal wave of simple tension and compression may be impressed upon a specimen, and has conducted interesting investigations into the generation of heat during the progress of fatigue tests; W. S. Farren and G. I. Taylor[54] have made accurate determinations of the heat generated during plastic extension in a static test; C. F. Jenkin[55] has developed apparatus with which fatigue tests can be conducted at speeds up to 5,000 cycles per second.

It is impossible in this article to include any summary of experimental results. The reader is referred to a recently published treatise by H. J. Gough,[56] in which a very clear and exhaustive account may be found, covering all aspects of fatigue as developed up to the latter part of the year 1924. (R. V. S.)

MATERNITY AND INFANT WELFARE.—The period 1910–26 was marked by an increasing consciousness in all civilised countries of the importance of decreasing the heavy losses to the community due to the high death-rate among women at childbirth and among infants under one year of age. There is a considerable body of new legislation intended to supplement and assist welfare agencies and to provide definite state assistance.

I. THE UNITED KINGDOM

The Maternity and Child Welfare Act 1918 gives wide and comprehensive powers to local authorities for taking action designed to preserve maternal and infant life. The passing of this Act consolidated the work commenced in 1906 by the St. Marylebone Health Society. Like nearly every other movement to fight disease, modest experiments by groups of social workers pointed the way to larger state and municipal action.

In 1910 there were 90 infant welfare centres in Great Britain, and by 1914 the number had risen to 400. Owing to the great impetus given to this service during the War, and to the passing of the Maternity and Child Welfare Act in 1918, there were in 1925 no fewer than 1,363 infant welfare centres under the local authorities and 759 voluntary centres, as well as 133 maternity institutions recognised by the Ministry of Health.

Legislation.—The various enactments bearing on the subject are the Factory and Workshops Act of 1901, which endeavours directly to protect the woman who has recently given birth to a child; the Midwives Act of 1902, which laid the foundation of a safe and efficient system of practice by midwives; the Notification

of Births Act of 1907 and the extension of the Act in 1915, which Miss Margaret Llewelyn Davies described as "nothing less than a welcome by society to each of its newly-born citizens, and a signal of help and a message of hope to every mother in the land." Under this Act the father or doctor or midwife must notify the public health authority within 36 hours of the birth of a child. Advice and help, free of charge, are then given by a woman health visitor. The National Health Insurance Act provides a maternity benefit of 40s. for an insured woman or the wife of an insured man.

The Ministry of Health, formerly the Local Government Board, encouraged local authorities to extend and develop their maternity and child welfare services. In a circular letter to local authorities issued in 1914 the board stated that an estimate had been laid before Parliament for a grant to be distributed to local authorities and voluntary agencies in respect of institutions or other provision for maternity and child welfare, that more extended and systematic measures than had hitherto been generally adopted were necessary. Sir Arthur Newsholme, in a report on maternal mortality in connection with childbearing, published in 1915, stated that "the present report is intended to draw attention to this unnecessary mortality from childbearing, to stimulate further local inquiry on the subject and to encourage measures which will make the occurrence of illness and disability due to childbearing a much rarer event than at present." His successor, Sir George Newman, 10 years later (1924), in his preface to Dr. Janet Campbell's *Maternal Mortality*, referring to the fact that approximately 3,000 mothers had died each year at childbirth for the previous 10 years, stated: "That is a serious and largely an avoidable loss of life at the time of its highest capacity and in its most fruitful effort."

Administration.—The local authorities carrying out maternity and child welfare schemes are the county councils, county borough councils and the councils of certain of the larger county districts—as a general rule those having a population of more than 20,000. These are in the main the authorities which adopted the Notification of Births Act referred to above, under which some work for mothers and babies was already being done before the passing of the Act of 1918. The regulations under which a grant is payable by the Exchequer of 50% of the approved net expenditure of local authorities, set out the services which may and should be comprised in a maternity and child welfare scheme, and from them the scope and content of the services may readily be understood.

1. The salaries and expenses of inspectors of midwives and of health visitors and nurses engaged in maternity and child welfare work;
2. The provision of a midwife for necessitous women and for areas insufficiently supplied with this service;
3. The provision, for necessitous women, of a doctor for illness connected with pregnancy and for aid during the period of confinement;
4. The expenses of a centre, *i.e.*, an institution for providing medical supervision and advice for expectant and nursing mothers and for children under five years of age, and medical treatment at the centre for cases needing it;
5. Arrangements for instruction in the general hygiene of maternity and childhood;
6. Hospital treatment for complicated cases of confinement and for children under five years of age found to need in-patient treatment;
7. The cost of food certified as being necessary to expectant and nursing mothers and for children where the case is necessitous;
8. Expenses of crèches and day nurseries and of other arrangements for attending to the health of children under five years of age whose mothers go out to work;
9. Accommodation in convalescent homes for nursing mothers and for children;
10. The provision of homes and other arrangements for attending to the health of children under five years of age of widowed, deserted and unmarried mothers;
11. Experimental work in relation to maternity and child welfare work;
12. Contribution by a local authority to voluntary institutions.

Exchequer grants on the same scale are also paid to voluntary agencies which carry out certain services to the satisfaction of the Minister of Health.

The annual expenditure on maternity and child welfare servic
provided by local authorities is approximately £1,500,000,
addition to which exchequer grants are made to voluntary age
cies. If to these figures is added the £1,500,000 paid in materni
benefit under the national health insurance scheme, a total of ov
£3,000,000 is spent each year on these services, without takin
account of the total expenditure of the voluntary agencies,
other benefits paid from health insurance funds and of the volu
tary hospital services.

Infant Mortality.—The services given at the centres by bo
lay and professional workers helped to secure the reduction
the infant mortality rate from 154 per 1,000 births in 1900 to
per 1,000 births in 1924. This gratifying result means that (c
culated on the average infant mortality of 1901–10) there was
1924 a further saving of 39,000 infant lives. "It also implies
better physical condition in children from one to five years
age, and a more enlightened understanding of personal and pu
lic hygiene" (Sir George Newman). While this saving of infa
lives is all to the good, it is disturbing to find on an analysis of t
statistics that the reduction in the infant mortality rate has
curred almost entirely subsequent to the first few weeks of
and that the death-rate of infants up to the age of four weeks
remained almost stationary, being 33 per 1,000 births in 1924
against 40 per 1,000 births for the period 1906–10.

Maternal Mortality.—So, too, in the case of maternal mortali
notwithstanding that Sir Arthur Newsholme reported in 1
that "800 mothers die each year in England and Wales as the
sult of childbearing whose lives would be saved if the experie
of the rest of England and Wales were as favourable as Londo
and that there would be a further saving of 1,100 lives of moth
secured annually in England and Wales if puerperal fever were
be eliminated "as it has been substantially from the experie
of many lying-in hospitals." Dr. Janet Campbell, 10 ye
later, writes that "avoidable maternal deaths are a matte
everyday occurrence," and that "puerperal infection leads
more deaths and more injury than any other complication
childbearing."

It has been shown that the mortality rate of very young ba
is nearly as high as it was early in the century. On examining
statistical returns of maternal mortality it is seen that while
death-rate of mothers at childbirth was 3·74 per 1,000 births
the period 1906–10, it was 3·70 per 1,000 births in 1924.

Here then is the problem. Improvements in general sanita
and public health services, a better education in public and
sonal hygiene, the maternity and child welfare services, the
vices provided under the National Health Insurance sche
have had no visible effect upon the vital statistics relatin
childbearing. Comparing the period 1906–10 with the year 19
that is to say, the period prior to the establishment and deve
ment of maternity and child welfare services by the local auth
ties with the latest complete figures available—it is seen
taking the 1906–10 period as 100, the relative mortality rates
1924 are:—

Maternal mortality	98·9
Infants under four weeks	82·5
Infants from four weeks to one year	54·5

It seems perfectly clear that the saving of the lives of the mot
and very young babies is one and the same problem. "The u
pected loss of the mother is a tragedy to the family. It is no
frequently associated with the death of the infant for whom
maternal life has been sacrificed, and is often followed by the
paired health and nutrition of the remaining children"
Janet Campbell).

Disability Among Married Women.—It has been pointed
that the mortality returns "reveal only a part of the total d
age and disability, and that an incalculable amount of unrepo
and often untreated injury and ill-health results from pregna
and labour." Statistics relating to the comparative heavy
dence of sickness amongst married women were presented to
Royal Commission on National Health Insurance which repo
in March 1926. In Appendix A to the report the Governn
actuary states:—

18. Another matter calling for attention, and in this case calling irgently, is the excess of the claims of married women over those of the unmarried.

\t the important groups of ages, 20–25, 25–30 and 30–35, the narried woman's rates of sickness are found to represent the folowing percentages of those of the unmarried class:

Ages	1921	1922	1923
	%	%	%
20–25	242	284	299
25–30	174	198	242
30–35	158	171	198

'he majority report of the Royal Commission recommended the rovision of improved maternity services "as and when funds re available to meet the cost." The minority report, however, eclared that "the high maternal death-rate and the great mount of sickness amongst mothers clearly prove the need of eorganisation and extension of maternity work," and recomnended that medical benefit under the Health Insurance scheme hould include medical attention at confinement and should be xtended to include the wives and dependants of insured men. 'he provision of more adequate services for women at childirth is a matter of urgent necessity. "If a woman can rely upon ecuring the services of a careful up-to-date practitioner, or upon ne attendance of a well-trained midwife who is able to obtain rompt and competent medical assistance in case of need, nearly l other conditions become of minor importance" (Dr. Janet ampbell).

Effect of Environment.—The development of antenatal serv-es appears to afford the most likely solution to the problem. egional distribution of the mortality does not point to industrial ctors as being the chief causes of deaths. At the same time, is not without significance that nine of the 10 county boroughs ving the highest rates of maternal mortality in the four years 19–22 were in Lancashire and Yorkshire, and seven of those ne towns, viz.: Halifax, Rochdale, Huddersfield, Bury, Oldham, ewsbury and Blackburn, in the report of 1914–5 are among the unty boroughs which exact "the heaviest toll of life from others in childbearing." Industrial areas can, however, be und with extremely low rates of mortality; the predominatingly orking class district of West Ham actually had in 1919–22 the west rate of maternal mortality of all the county boroughs. The same county borough had the lowest rate among the metpolitan boroughs in 1914. In the counties of Lancashire and rkshire it is the practice for a considerable proportion of mard women to be employed in the textile mills, and it is difficult resist the conclusion that the nature of their employment, tother with the strain of managing the household and bearing ge families, is in no small degree responsible for the unenviable sition which the towns occupy and have occupied for so many ars. The puerperal death-rate in Wales has always been higher an that in England, and, until recently, than in Scotland. at is probably due, not so much to any special cause peculiar to les, as to the fact that, broadly speaking, the whole country either extremely rural or highly industrial. The services availe in most rural areas leaving much to be desired, and the exdingly hard life associated with the mining industry, must factors contributing to the high maternal mortality rates closed.

An enlightened public opinion would encourage and, where essary, compel the local authorities to provide the services sidered by the experts to be essential. The medical profession the knowledge; administrators, local and national, are capaof creating the administrative machinery; there is no lack of intary helpers; the provision of the necessary finance and the operation of the mothers are the two factors which depend n education.

II. THE UNITED STATES

The most important development in this field was the passage by Congress in 1921 of the Maternity and Infancy Act, popularly known as the Sheppard-Towner Act. This Act authorised an annual appropriation of $1,240,000 for a five-year period, of which a sum not to exceed $50,000 may be expended by the U.S. Children's Bureau for administrative purposes and for the investigation of maternal and infant mortality, the balance to be divided among the states accepting the Act as follows: $5,000 unmatched to each state, and an additional $5,000 to each state if matched; the balance to be allotted among the several states on the basis of population and granted if matched.

The national administration of the Act is lodged with the Children's Bureau of the U.S. Dept. of Labor; local administration in the states is in the child-hygiene or child-welfare division of the state agency of health or, where such a division does not exist, the agency designated by the state. In 1925, 43 states—all except Connecticut, Illinois, Kansas, Maine and Massachusetts—had accepted the benefits of the Act, and approximately $1,000,000 was being expended by the national Govt. in subsidies to the states. In 1924 the benefits of the Act were made available to the Territory of Hawaii, which has also accepted and matched the funds available.

Results of the Act.—The report for 1925 of the activities undertaken by the states under the terms of this Act shows continued progress as old activities have spread over a greater territory and new activities have been initiated. These have for their object: (1) better infant care through the teaching of mothers; (2) better care for mothers through education as to the need and value of skilled supervision during pregnancy, childbirth and the lying-in period; and (3) more widespread medical and nursing facilities so that adequate maternity and infancy supervision will be available to all who need it. Children's health centres or conferences and pre-natal or maternity centres or conferences are everywhere recognised as the best agencies for teaching the hygiene of maternity and infancy. An objective in most of the states is the state-wide establishment of permanent, locally supported centres. Demonstration conferences have been held and intensive pieces of work undertaken by the states when there was evidence of special need. In the main these activities have been for the benefit of rural communities and small towns.

State reports of the work during the fiscal year 1925 show 10,802 child-health conferences held by 43 states administering the Federal funds, with 278,016 infants and children of preschool age examined, and 622 children's health centres established through the efforts of the states. Since 1920 child-hygiene or child-welfare divisions or bureaux have been organised in the departments of health in 14 states, so that in all except one state (Colorado) these departments now have an organised agency promoting child health.

Ten states have been admitted to the United States birth-registration area since 1920. At present (1926) 33 states and the District of Columbia (all except Alabama, Arizona, Arkansas, Colorado, Georgia, Idaho, Louisiana, Missouri, Nevada, New Mexico, Oklahoma, South Dakota, Tennessee, Texas and West Virginia) are in the birth-registration area, comprising 75·9% of the total population of the United States. In 1915 the infant mortality rate for the birth-registration area was 100; in 1920, 86; and in 1924 (provisional figures), 72. A general reduction during the five years 1920–5 in the rates in both rural and urban areas is indicated.

On the face of the figures, maternal mortality from all causes appears to have been increasing in the United States. Analysis of the statistics shows that the certification of the causes of deaths has improved during the last 20 years. If allowance is made for the probable effect of this improvement in certification, the mortality from puerperal septicaemia has fallen throughout the period instead of increasing up to 1911 and falling since that time, as the figures, if taken at their face value, would indicate, and the mortality from other puerperal causes has been approximately stationary. After allowances are made for the margin of errour in the statistics of the United States and of other countries, it seems probable that the rate in the United States is actually considerably higher than in most foreign countries. The maternal death-rate, per 1,000 live births in the birth-registration area of the United States, was 6·6 in 1924, with only five states having a rate below 6.

Great emphasis is being placed on pre-natal supervision by the state bureaux of maternal and infant hygiene, but the programme of work was only just getting under way in 1926. Reports of activities undertaken under the Maternity and Infancy Act show 3,781 pre-natal conferences with more than 36,000 women in attendance, and 65 permanent pre-natal centres established. More than 400 midwife classes were held in 20 states, with an enrolment of more than 10,600 midwives, of whom more than 8,000 completed a somewhat formal course of instruction. Most of these were negro midwives who had had little or no previous training. Women in isolated rural districts are being reached by "pre-natal letters" and itinerant conferences. More generally accessible hospital care during confinement is also receiving consideration.

In 1925, 22 states—Arkansas, Arizona, Colorado, Florida, Idaho, Iowa, Kansas, Kentucky, Louisiana, Massachusetts, Minnesota, Montana, Nebraska, Nevada, New Hampshire, New Jersey, North Carolina, Pennsylvania, Rhode Island, South Carolina, Utah, Virginia—and the District of Columbia have laws making medical inspection of schools mandatory, although in some of these states the examination is required only in case of infectious disease. In 8 states—Alabama, Connecticut, Georgia, Indiana, Maine, New York, West Virginia and Wyoming—it is mandatory for certain districts. Five states—Iowa, Kansas, South Dakota, Nevada and Utah—have laws specifically requiring examination of the teeth of school children; and in 12 other states and the District of Columbia it is included in the requirement of a complete examination. Thirty-three states—all except Arizona, Arkansas, Colorado, Florida, Kansas, Louisiana, Montana, Nebraska, New Hampshire, New Mexico, Oklahoma, South Dakota, Texas, Vermont, Wyoming and the District of Columbia—have laws with reference to physical education in elementary schools which are either mandatory or mandatory in effect. The teaching of health and health habits as distinguished from either medical inspection or physical education has greatly increased in recent years.

In 1923 two private national organisations, the American Child Hygiene Assn. and the Child Health Organisation of America, united to form the American Child Health Association. This association has made an important survey of child health in 86 cities having a population of from 40,000 to 70,000 and has supervised the demonstrations in child hygiene for The Commonwealth Fund and done general educational work in the field of child health.

MATHEMATICS (*see* 17.878).—In the great *Principia Mathematica*, published in 1911, mathematics is rigorously deduced from a few primitive propositions of logic. Since then, not to speak of improvements of detail effected by Sheffer and Nicod, the *Principia* has been subjected to fundamental criticisms which have induced many workers to abandon altogether its line of approach.

I. MATHEMATICAL LOGIC

Theory of Types.—In attempting to provide a firm logical basis for the theories of infinite aggregates and irrational number developed during the 19th century by Cantor and Dedekind,
the chief theoretical difficulty is to avoid the famous parado
of the theory of aggregates. These are direct contradictio
which arise as a result of pursuing apparently ordinary and legi
mate mathematical arguments. Such a state of things is intole
able, and shows that there must be something radically wro
with our fundamental ideas. Whitehead and Russell discover
that behind each contradiction lay a "vicious-circle fallacy
due to neglecting the fundamental principle that what involv
the whole of a given totality cannot itself be a member of t
totality. In order to avoid such fallacies they put forward th
Theory of Types, which consisted of two rather different par
The first part asserted that things were of different logical typ
and that for any predicate there was only one type of subje
of which the predicate could significantly be predicated; a
plying it to a subject of any other type would give not falseho
but literally nonsense. According to this principle many of t
paradoxes consist of sentences, which, though grammatica
correct, are nevertheless strictly meaningless, and the cont
dictions are thus completely removed. But not all the pa
doxes could be dealt with thus, and the others required the seco
part of the theory of types, which distinguished further differe
orders of predicates applicable to the same type of subject.

For instance, the quality of having all qualities of a certa
sort cannot itself be a quality of that sort, or it would be involv
in its own definition, but must be a quality of a higher ord
So, in order to avoid vicious circles, we must never speak of
qualities generally, but only of all qualities of a certain ord
If all statements of this kind are made precise as to the order
qualities involved, all the paradoxes which escape the first pa
of the theory of types in their turn disappear.

Axiom of Reducibility.—The theory of types is thus co
pletely successful in avoiding the contradictions, but this is o
half the problem. The arguments leading to contradiction m
be invalidated, but this must be done without also invalidati
the arguments used in accepted mathematics; and in this Whi
head and Russell failed, for the restrictions imposed by the s
ond part of the theory of types upset an enormous part of or
nary analysis, and this catastrophe was only averted in *Princi*
by the introduction of the axiom of reducibility. This axi
asserts that for any predicate of higher order there is a predic
of the lowest order having the same extension (*i.e.*, applying
the same subjects) as the one of higher order. This implies t
any class defined as the extension of a higher order predicate
also be the extension of a lowest order predicate; so that thus
totality of classes, whose members are of a given type, can be
tained from the totality of lowest order predicates applicable
that type and will be a legitimate totality. In this way the the
of irrational numbers and the other parts of mathematics thre
ened by the theory of types can be saved, if we are prepared
accept the axiom of reducibility. But this axiom cannot possi
be regarded as self-evident, and there is really no reason wh
ever for supposing it to be true, so that anything which can o
be proved by assuming it cannot be regarded as proved at all

Intuitionist Views.—This point was especially emphasi
by Weyl in *Das Kontinuum* (Leipzig, 1918) who went so far a
reject not merely as unproved, but as evidently unprova
much of the general theory of real numbers, bounds, limits
continuous functions, to say nothing of more recent advan
He proposed to confine mathematics to the narrower body
truth, which could be proved not merely without the axiom
reducibility but without using higher order predicates at
Since then Weyl has moved still further from the standpo
of *Principia Mathematica*, and in his latest work (*e.g.*, in *Ma*
matische Zeitschrift, 1921) he appears as a follower of Brou
who is regarded as the leader of the "intuitionist" school.

The Excluded Middle.—Brouwer's principal thesis is his de
of the law of excluded middle, which may be illustrated by a
of the following kind. Suppose we wish to establish the existe
of a number having a certain property; then we may argue th
A certain condition, say p, must either be fulfilled or not; if
true, we can make a construction which will give a number of
required kind; if p is false, we can also make a construction

uch a number, though a different construction from the previous ne. So we shall conclude that in either case there exists a num- er having the required property. Such an argument would, ccording to Brouwer, be illegitimate, because if, as often hap- ens, we could not tell whether p were true or false, we should ot know how to set about actually constructing the number in uestion. It would be wrong, he thinks, to argue by the law f excluded middle that, because it could not be true in either ise that all numbers have not got this property, there must be ne number at least which has it.

This criticism, which is supported by several eminent authori- es, would annihilate considerable portions of modern mathe- atics. There are, however, many thinkers to whom Brouwer's iticism seems to have no force whatsoever, and who are deter- ined to find a theory of the foundations of mathematics which ill not involve the rejection of any generally accepted parts of e subjects; and of their views we must now give some account.

Axiom Systems.—There are first Zermelo, Fränkel and others, ho are working at the construction of axiom systems for the eory of aggregates; they propose to cease using the word class aggregate in its ordinary sense, whatever that may be, but mean by it anything satisfying certain axioms; these axioms ll be constructed so as to permit the deduction of all the ordi- ry theory of aggregates, but avoid all the contradictions. But om a philosophical point of view this shirks the real problem, ich is to clear from contradiction the notion of class and other ied notions which occur in mathematics, when, for instance, we eak of the class of prime numbers, as well as outside it.

Formalists.—The most prominent opponents of the intuition- s are, however, the formalists, of whom Hilbert (see especially *athematische Annalen*, 1922) is the leader. This school regards thematics as consisting of meaningless symbols manipulated cording to formal rules, thus reducing it to something of the ture of a game of chess. Such an account of mathematics is olly inadequate; since if " two " and " three " were meaning- s marks on paper there could be no difference in meaning ween " two shillings " and " three shillings." But the formal- attitude, although hopeless philosophically, may be useful dealing with particular questions, and the essential novelty of bert's work consists not in his formalist theory, but in the positions he has proved or hopes to prove about mathemati- formulae. The chief of these propositions is that it is impossi- to deduce a contradiction by permissible operations from the oms of mathematics, including the law of excluded middle.

This demonstration is only required to convince the sceptics intuitionists, who will not be satisfied with the simple argu- nt that the axioms are true and that therefore no contradiction be logically deduced from them. Hence it is essential not use in the demonstration any principle which the sceptics ibt. This appears to be possible, since, owing to the finite ure of any piece of mathematical reasoning, in proving that it s not lead to contradiction we shall only have to employ the of excluded middle for finite ranges, for which everyone nits its validity. The science on which Hilbert is now (1926) aged, which takes for its subject matter the meaningless for- lae of mathematics, he calls *metamathematics*, and believes it to apable of establishing many important results relating to the tiplicative axiom or axiom of selections and to the continuum blem. Interesting, however, as his work is, it does not offer satisfactory account of the foundations of mathematics as ience, but only deals with it as a game, and contributes no e to the solution of the main problem than does the annihilat- scepticism of the intuitionists.

athematical Induction.—So that, in view of the bankruptcy ll other proposals, it would seem that the true account of the ter must be on the lines of that of Whitehead and Russell, ough this cannot be correct in detail owing to the unsatis- ory nature of the axiom of reducibility. Of great interest this point of view is the new work in the second edition of *cipia Mathematica* (vol. i, 1925) and in particular the new ry of mathematical induction, which by most ingenious ments is established without using the axiom of reducibility. Unfortunately the authors do not see their way to constructing a similar account of Dedekindian Series, for which and for all that part of analysis which depends upon it we are left without any justification.

In this new edition of *Principia Mathematica* some use is made of the theories of *Tractatus Logico-Philosophicus* by Ludwig Wittgenstein, which, although mainly concerned with more purely philosophical problems, also contains contributions of fundamental importance to our subject. Of one of the principal problems in particular he has given an original and possibly final solution; but in order to understand this it is necessary to go back a little.

Mathematics and Logic.—One of the chief objects of the work of Frege and Russell was to reduce mathematics to logic, to show that all mathematical concepts could be defined in terms of " logical constants," and that all mathematical propositions could be deduced from those of formal logic; so that mathematics and logic became one and the same subject. Granting the validity of this reduction, doubt still remains as to what is the peculiar characteristic of logical or mathematical propositions, and how they differ from all others. This question Russell answered in 1903 by saying that logic or mathematics consisted of all true propositions, which were hypothetical in form and contained no constants except logical constants; this amounts practically to saying that any completely general true proposition is a proposition of logic. It subsequently became clear that this definition was much too wide, and that it was necessary to distinguish the propositions which could be stated in purely logical terms and were in fact true, from those which logic alone could assert to be true, which form the science of logic and mathematics. And the distinguishing characteristic of this smaller group of propositions which logic can assert to be true had yet to be found.

Wittgenstein's Work.—This problem Wittgenstein has probably solved; his answer is complicated by the fact that he does not accept the reduction of mathematics to logic, and gives different accounts of the propositions of logic and those of mathematics. Of these his theory of logical propositions is the more important; and if, as is quite possible, his criticisms of the reduction of mathematics to logic are unsound, it would entirely supersede his theory of mathematics, which is given only in barest outline.

Wittgenstein's account of the propositions of logic is that they are tautologies, in a sense of which a precise definition is given in terms of his theory of propositions in general. Any proposition, he maintains, is the expression of agreement and disagreement with certain ultimate possibilities, the possibilities of existence and non-existence of atomic facts. A proposition which agrees with every possibility is a tautology; one which disagrees with every possibility is a contradiction. An ordinary proposition asserts something to be the case and is true if it is the case; a tautology on the other hand asserts nothing but agrees with every possibility and is therefore true unconditionally. This account can be made to cover not only what are called in *Principia Mathematica* " elementary propositions," but also general propositions which involve apparent variables.

Symbolism.—But the importance of Wittgenstein's work does not only consist in his having defined the propositions of logic, and hence possibly those of mathematics, but also in his theory of symbolism, which seems capable of far-reaching applications to the theory of types. The theory of symbolism may indeed be expected to be relevant for the following reason. There is an obvious division of the paradoxes into two groups, which is entirely overlooked in *Principia Mathematica*. The first group of contradictions, such as those about the class of classes not containing themselves and the greatest ordinal, can be stated in purely logical or mathematical terms. They would actually occur in a mathematical treatise if it investigated the problems in question. The remaining contradictions, such as Richard's paradox, involve, besides mathematical terms, terms drawn from psychology or epistemology, such as knowing, asserting, naming or meaning. These contradictions are not therefore purely mechanical, and the responsibility for them need not, as must that for the first group, lie with faulty mathematics or logic, but may lie in faulty ideas of knowledge and symbolism. This was the view taken of them by Peano; but it cannot be regarded as satisfactory until an adequate explanation is given of where exactly the fault lies. The probability that it lies in the epistemology and not in the mathematics, is strengthened by the fact that this grouping of the contradictions into purely mathematical and mixed coincides with their grouping according to whether their solution in *Principia* requires the first or second part of the theory of types. So that the first part of the theory, which is undoubtedly sound, will suffice for the purely mathematical contradictions, and if the mixed contradictions can be shown to be due to the epistemological element, there may no longer be any need for the second part of the theory of types, which requires the axiom of reducibility and is so responsible for the whole trouble.

By using the work of Wittgenstein a solution has been constructed along these lines, on which the theory of types is so modified that all need for an axiom of reducibility disappears, and mathematics consists entirely of tautologies in Wittgenstein's sense.

II. THEORY OF NUMBERS

In the article NUMBER (19.847) an excellent summary is given of the classical theory. Modern mathematics has seen the rise of a new theory, the " analytic " theory, which has developed with great rapidity, and has almost monopolised the attention of arithmeticians.

(*a*) *Theory of Primes.*—The modern developments of the theory of numbers depend in the main on the application to the theory of the ideas of the theory of functions of a complex variable (*see* 11.301). It was in the theory of the distribution of primes that these ideas first bore fruit.

It is usual to write $\pi(x)$ for the number of primes less than x. It has been known since Euclid that the number of primes is infinite, that is to say that $\pi(x)$ tends to infinity with x. The central problem of the theory has been the determination of the order of magnitude of $\pi(x)$ when x is large, and its solution is embodied in the *Primzahlsatz*, or " prime number theorem," expressed by the formula

$$\pi(x) \sim \frac{x}{\log x}$$

where the symbol $\sim$ expresses the fact that the ratio of the two functions tends to unity. This theorem, conjectured by A. M. Legendre (1798) and C. F. Gauss (about 1792), was first proved by J. Hadamard and Ch. J. de la Vallée Poussin in 1896. The real founder of the modern theory, however, was B. Riemann, who, in a famous memoir published in 1859, first indicated the road along which subsequent research has progressed. Riemann did not prove the prime number theorem; strangely enough, he did not mention it, his object being to obtain, not an asymptotic formula for $\pi(x)$ but an exact expression in the form of an infinite series. Nor did Riemann attain the goal at which he aimed, his analysis, profound and beautiful as it is, being altogether incomplete and inconclusive. But it was Riemann who first recognised where the key to the solution lay, viz., in the study of the " Riemann zeta-function,"

$$\zeta(s) = \zeta(\sigma + it) = \Sigma n^{-s} = \Pi\left(\frac{1}{1-p^{-s}}\right)$$

(where $n = 1, 2, 3, \ldots$, and p runs through the series of primes), considered as a function of the complex variable s. Riemann established some, and conjectured others, of the properties of $\zeta(s)$; one famous conjecture, that all the complex zeros of $\zeta(s)$ lie on the line $\sigma = \frac{1}{2}$, remains unsettled to this day.

Riemann's memoir bore no fruit for over 30 years, when the way was cleared by the researches of Hadamard in the theory of analytic functions (*see* FUNCTION, 11.301 *seq.*). These researches led Hadamard himself, de la Vallée Poussin, and other writers, to a proof not only of the prime number theorem but of very much more. Thus de la Vallée Poussin proved that the logarithm integral $\mathrm{Li}x = \int_2^x \frac{dt}{\log t}$ represents $\pi(x)$ with an error of lower order than $x(\log x)^{-k}$, where k is any number however large. He also investigated the distribution of primes of a linear form $am+b$ or a quadratic form $am^2+bmn+cn^2$ where a, b, c are integers without common factor, showing, for example, that the primes are, on the average, equally distributed between the various arithmetical progressions $am+1$, $am+2$, $\ldots$, as had been conjectured long before by P. G. Lejeune Dirichlet. There is a corresponding theory for the " prime ideals of the " corpus " associated with any algebraic number. The ar logue of Riemann's zeta-function was discovered by R. Dedekin but it is only recently that, in the hands of E. Hecke and E. Landa the development of the theory has been pushed to a point cor sponding with that of the ordinary theory.

The outstanding unsolved problem of the theory is that of t determination of the order of the *difference* $\pi(x) - \mathrm{Li}x$. This proble is bound up essentially with Riemann's unproved hypothesis co cerning the zeros of $\zeta(s)$. If Riemann's hypothesis is true, the ma imum order of the difference differs from that of $\sqrt{x}$ by logarithn factors only. In any case the difference assumes values *of eit sign* which tend to infinity with x. This theorem, proved by J. Littlewood in 1914, disposes of the old conjecture of Gauss a B. Goldschmidt that $\pi(x)$ is always less than $\mathrm{Li}(x)$.

Apart from applications to the theory of primes, there is a lar literature connected with the pure theory of $\zeta(s)$. It has been sho by H. Bohr, E. Landau and F. Carlson that (to put it rough nearly all the zeros lie very near the critical line; by G. H. Har and J. E. Littlewood that (equally roughly) a considerable prop tion lie actually on it. But the hypothesis itself remains unprov

(*b*) *Additive Theory.*—The " additive " theory of numbers cludes Combinatory Analysis (*see* 6.752), Partitions (*see* 19.86, the theory of the representation of numbers by sums of squar cubes, or higher powers, and so forth.

The central problem is that of determining (exactly or appr imately) the number of representations of an arbitrary positi integer n in the form $a_1+a_2+ \ldots +a_s$, where the a's are nu bers of some special type (*e.g.* squares), and s may be fixed or u restricted, according to the particular problem envisaged. There i fundamental difference between the " additive " theory and wh may be called the " multiplicative " theory, in which the cent idea is that of the resolution of a number into prime factors. Analy cally, this difference expresses itself as follows: the multiplicati theory depends on the theory of " Dirichlet's series " of the ty $\Sigma a_n n^{-s}$, the additive theory on that of power series $\Sigma a_n x^n$. A gre deal of the additive theory is purely algebraic, and is intimat bound up with the theory of elliptic functions. This side of the theo (founded by L. Euler) has been developed to a high pitch by Engl mathematicians, notably A. Cayley, J. J. Sylvester, and P. A. Ma Mahon, while more recently the methods of complex function theo have been applied to the theory and an " analytic additive " theo has been founded. Among many curious results we may mention t theorem of S. Ramanujan, that the numbers of the unrestrict partitions of numbers of the forms $5m+4$, $7m+5$ and $11m+6$ divisible by 5, 7 and 11 respectively.

One of the most remarkable problems of the additive theory " Waring's Problem." It was asserted by E. Waring (1782) that a number n is the sum of at most 4 squares, 9 positive cubes, 19 fou powers, and, generally, $g(k)$ powers, where $g(k)$ is a number pending on k alone and not on n. This problem—in so far as it sim asserts the existence of *some* such number $g(k)$—was solved by Hilbert in 1909. J. L. Lagrange (1774) proved that $g(2)=4$ (a number is the sum of 4 squares, and some numbers not of les and E. Wieferich (1909) that $g(3)=9$ and $g(4) \leqq 37$. Only a fin number of numbers (probably only 23 and 239) require more cu than 8 (E. Landau, 1908), while an infinite number require 4 at lea and only a finite number of numbers require more than 19 fou powers (G. H. Hardy and J. E. Littlewood, 1924), while an infin number require 16 at least; and asymptotic formulae for the numb of representations have been found. But our knowledge of t field is still extremely incomplete.

The " empirical theorem " of Chr. Goldbach, that every ev number is the sum of two primes, has also received a considera amount of attention, but is still unproved. Among other unsolv problems of the same character may be mentioned that of prov the existence of an infinity of primes of the form m^2+1 or (m generally) am^2+bm+c. This problem is not to be confused with t problem of primes $am^2+bmn+cn^2$, solved by de la Vallée Poussin.

(*c*) *Miscellaneous Investigations.*—The work of Dirichlet a L. Kronecker on the approximation of irrational numbers rationals has led to extensive investigations lying on the bor line between arithmetic and analysis, developed above all H. Minkowski under the titles of *Diophantische Approximati* and *Geometrie der Zahlen*. The central idea in this theory is th of the lattice (*Gitter*).

A lattice point (*Gitterpunkt*) in space of any number of dimensi is a point with integral co-ordinates, and most difficult and fascinati problems arise when we consider the number of lattice points wh lie within a volume of specified form in n-dimensional space. Th Minkowski proved that any convex figure in space of two dimensi with symmetry about a centre, its centre at a lattice point, and area 4, includes other lattice points besides its centre; with a wh series of corresponding theorems concerning more general configu tions. Another class of lattice-point problems is exemplified by t

" circle " problem of Gauss and W. Sierpinski, that of determining approximately the number of lattice points inside the circle $x^2+y^2=n$ when n is large. A first approximation is naturally given by πn, the area of the circle, but the estimation of the error is a problem of exceptional difficulty. This problem and the analogous problem for the hyperbola $xy=n$ (Dirichlet's divisor problem) were connected with the theory of $\zeta(s)$ [see (*a*) *supra*] by Landau. These problems also are susceptible of manifold generalisation. And in all these problems, we observe the dominating and irresistible tendency of modern higher arithmetic, the tendency to abandon its ancient tradition of isolation and assimilate itself so far as possible to the theory of functions, in order to utilise the immensely powerful weapons which the latter theory alone can provide.

There is one famous problem in which no such reduction of arithmetic to analysis has been effected. " Fermat's last theorem " asserts that there is no integral solution of $x^n+y^n=z^n$ (other than the trivial solution $x=z$, $y=0$) for any value of n greater than 2. t was the attempt to prove this theorem that led to the whole development of the theory of algebraic numbers; but, in spite of the wide-spread attention which it has excited, and the extreme impor-ance of the general theories of which it has been the starting point, he theorem itself remains unproved, though important additions have been made recently to our knowledge by A. Wieferich, D. Mirimanov, L. E. Dickson, and H. S. Vandiver. Thus Wieferich proved hat the theorem holds for odd prime values of n, and values of x, , z, not divisible by n, unless $2^{n-1}-1$ is a multiple of n^2.

One old conjecture has been definitely disposed of. Mersenne sserted that 2^n-1, where n is a prime not exceeding 257, is prime when, and only when, $n=1, 2, 3, 5, 7, 13, 17, 19, 31, 67, 127, 257$. This statement contains at least four errors, relating to the values 1, 67, 89, 107; and it need no longer be taken seriously.

BIBLIOGRAPHY.—An indispensable work for the serious student of igher arithmetic (on any of its sides) is L. E. Dickson, *History of e Theory of Numbers*, 1920. This work is not, however, specially oncerned with the analytic theory.

For general accounts of the theory of primes see the article " Die euere Entwicklung der Analytischen Zahlentheorie " by H. Bohr nd H. Cramer in the *Encyklopädie der Mathematischen Wissenchaften* (2C8); E. Landau, *Handbuch der Lehre von der Verteilung der rimzahlen* (1909), and *Einführung in die elementare und analytische Theorie der algebraischen Zahlen* (1918).

For the additive theory see P. A. MacMahon, *Combinatory nalysis* (1915–6), and *An Introduction to Combinatory Analysis* 921); P. Bachmann, *Niedere Zahlentheorie:* 2. (*Additive Zahlen-eorie*) (1910); G. H. Hardy, *Some Famous Problems of the Theory f Numbers* (1920). For Fermat's last problem see P. Bachmann, *as Fermatproblem* (1917); L. J. Mordell, *Four Lectures on Fermat's ast Problem* (1921).

Comparatively little of recent work is accessible in a connected rm, and the study of the original memoirs is indispensable.

III. THEORY OF SERIES

The most striking modern developments in the theory of ries (*see* 24.668; 10.753; 12.956) have also been suggested by he development of the theory of functions.

The theory of functions of a real variable has been revolution-ed by the ideas of E. Borel and H. Lebesgue, and this has in-ired a corresponding revolution in the theory of Fourier's ries and " series of orthogonal functions " generally.

A system of functions $\phi_m(x)(m=1, 2, 3, \ldots)$ is said to be *thogonal* if

$$\int_a^b \phi_m(x)\phi_n(x)dx=0(m\neq n) \qquad (1)$$

he simplest examples are obtained by taking $\phi_m(x)$ to be cos mx sin mx and the interval (a, b) to be $(0, 2\pi)$; or $\phi_m(x)$ to be Legen-e's polynomial $P_m(x)$ and (a, b) to be $(-1, 1)$. There is then a mple procedure by which we may endeavour to expand an ar-trary function $f(x)$ in the form of a series $\Sigma a_m\phi_m(x)$, viz., by mul-lying this series by $\phi_m(x)$ and integrating over the interval (a, b): e formula thus suggested is

$$f(x)=\Sigma a_m\phi_m(x),\ a_m=\left(\int_a^b f(x)\phi_m(x)\,dx\right)\Big/\left(\int_a^b \phi^2{}_m(x)\,dx\right) \qquad (2)$$

A more accurate analysis of this procedure raises a multitude of ofoundly interesting and difficult questions. On the one hand we ay start from a series with arbitrary coefficients a_m, and inquire hether there exists a function which stands to it in the relation pressed by the equation (2). In particular, given a trigonometrical ies $\Sigma a_m\cos mx$ or $\Sigma b_m\sin mx$ or, more generally $\Sigma(a_m\cos mx$ $b_m\sin mx)$, with arbitrary coefficients, we may ask whether it is Fourier's series, that is to say, whether there is a function $f(x)$ such at a_m and b_m are given by Fourier's integral formulae. On the her hand, we may start not from an arbitrary series but from an bitrary function $f(x)$, form the coefficients (a_m or b_m) by Fourier's mulae or the more general formulae (2), and then inquire whether e formal development thus obtained is convergent, and whether, if nvergent, it represents the function $f(x)$ and so forth.

The problems thus raised are among the most difficult of modern thematics; and a very cursory examination of them is enough to show that the methods of the older analysis are not sufficiently powerful for their solution. It is essential that we should enlarge our conceptions, on the one hand, by taking account of the modern generalisations of the notion of an integral, and, on the other, by adopting a broader view as to what is meant by the " sum " of an infinite series.

The modern theory of functions of a complex variable (*see* 11.301) points to the same conclusion. A function $f(z)$ of the complex variable z, regular for $z=z_0$, is defined throughout a certain circle whose centre is z_0 by a power-series $\Sigma a_n(z-z_0)^n$; but the region of existence of the function is very generally more extensive than the circle of convergence of the series; and this fact has led, during the last generation, to a mass of work on the problem of " analytic continuation." This problem is that of discovering analytic representations of the function, whether by integrals, or by continued fractions, or by series of a different form, which are valid throughout a wider region than that in which it is represented by the original power series. Here also we are confronted by the need for a scientific theory of divergent series.

There are passages in the older analysts (*e.g.*, in L. Euler) which suggest a half-conscious anticipation of modern ideas. But it is roughly true to say that they did not concern themselves with the precise meaning of the infinite series of which they made such effective use. A. L. Cauchy and N. H. Abel were the first to give a precise definition of the " sum " of a series $a_0+a_1+a_2+\ldots$ or Σa_n, viz., as the limit of $s_n=a_0+a_1+\ldots+a_n$ when n tends to infinity $(n\to\infty)$. Such a series as $1-1+1-\ldots$ has then *no* sum, for s_n is alternately 1 and 0; and it was the tendency, for many years after Cauchy and Abel, to banish such series from analysis entirely. A school of mathematicians survived, among whom one may cite A. de Morgan, who viewed this tendency with obvious discontent, but there was no escape from the conclusion that the followers of Cauchy and Abel were right. It is impossible to say " the sum of Σa_n is so-and-so " except after framing an accurate definition of " sum "; the definition of Cauchy and Abel was the only definition; and, until some new and wider definition was offered, that was the end of the matter.

We may define the meaning of a mathematical word or symbol as we please, provided only that the definition is free from contradiction. Given a sequence of numbers $a_1, a_2, \ldots$ we may associate with the sequence a number s in any manner that we please, and we may say, if we like, that s is the " sum " of the series. We might say, for instance, that the " sum " of every infinite series is, by definition, zero. This definition would be perfectly legitimate but futile, because it would reduce all equations involving infinite series to the trivial form $0=0$; and confusing, because it would conflict with Cauchy's definition. Cauchy's definition is only one among many, but it is admittedly the most important, and a new definition is only likely to be of value if it is consistent with the standard definition. It must satisfy what is called the *condition of consistency*; it must apply to all convergent series, and give a " sum " equal to their sum in the ordinary sense. Its value for analysis will then be measured by the extent and importance of the class of non-convergent series to which it attributes a " sum."

The simplest and most important of the definitions which have been given is that of the " first arithmetic mean." Suppose that $s_n=a_0+a_1+\ldots+a_n$ and $\sigma_n=(s_0+s_1+\ldots+s_n)/(n+1)$, the arithmetic mean of the first $n+1$ values of s_n. If s_n tends to a limit, σ_n tends to a limit also, and the two limits are the same; but σ_n may tend to a limit when s_n does not. For example, if $a_n=(-1)^n$, $s_{2n}=1$ and $s_{2n+1}=0$, and s_n does not tend to a limit; but σ_n tends to the limit $\frac{1}{2}$. If now we agree to call the limit of σ_n, whenever it exists, the " sum " of the series Σa_n, our new definition is in perfect accord with Cauchy's definition, but is applicable to an extensive class of series for which Cauchy's definition fails. It therefore fulfils the conditions required for a theory of divergent series.

The most striking illustration of the importance of these ideas is to be found in the theory of Fourier's series (*see* 10,753). The Fourier's series of a *continuous* function $f(x)$ is not necessarily convergent; further conditions on $f(x)$, of a much more artificial character, are required to ensure convergence. It was, however, shown by L. Fejér that the Fourier series of any continuous function is " summable " by the procedure indicated above; that is to say, that the arithmetic mean σ_n tends to a limit equal to the value of the function; and this fundamental result has been the starting point of a mass of modern research.

Another important definition attributes to the series as " sum " the value of the limit of the power series Σa_nx^n when x tends to 1 through positive values less than 1. A third (of particular importance in complex function theory) was advanced by Borel; and all of these definitions have entailed a host of still more general definitions.

BIBLIOGRAPHY.—For the general theory of divergent series see E. Borel, *Leçons sur les séries divergentes* (1901); T. J. I'A. Bromwich, *Introduction to the Theory of Infinite Series*, ch. x. (1908); G. H. Hardy and M. Riesz, *The General Theory of Dirichlet's Series* (1915). For the theory of Fourier's series, H. Lebesgue, *Leçons sur les séries trigonométriques* (1912); Ch. J. de la Vallée Poussin, *Cours d'analyse infinitésimale*, 2nd ed., vol. 2 (1916); E. W. Hobson, *The Theory of Functions of a Real Variable* (1907, 2nd ed., 1925). The general theory of series of orthogonal functions is, for the most part, still only to be read in the original memoirs, or in works on the theory of integral equations. A very important generalisation of the concept of a Fourier's series has been developed recently by H. Bohr in a series of memoirs in the *Acta Mathematica*.

IV. THEORY OF FUNCTIONS

The theory of functions (*see* 11.301, 14.53) has two great branches, the real and the complex theories. Recent advances in the complex theory, important as they are, have been of too technical a character for rapid summary. The real theory, on the other hand, has been remodelled from its foundations. The older form of the theory was cumbrous and unattractive. The modern theory has the aesthetic character required of a first-rate mathematical science, and its development has been perhaps the most striking achievement of modern analysis.

1. *Sets of Points.*—The theory of functions of a real variable is based upon the theory of aggregates (*see* 19.847–850) and in particular the theory of " sets of points." A set of points S is an aggregate of real numbers x, such as the aggregate of rational numbers, or of irrational numbers, in the interval $(0, 1)$. A number ξ is said to be a " limit point " (*Häufungstelle*) of S if every " neighbourhood " of ξ, that is to say every interval $(\xi-\epsilon, \xi+\epsilon)$ including ξ, contains points of S other than ξ itself. A limit point of S may or may not belong itself to S. Thus every number of $(0, 1)$, rational or irrational, is a limit point of the set S of rationals of $(0, 1)$. If every limit point of S belongs to S, S is *closed*. If every point of S is a limit point, S is *compact* or *dense*. A set which is both closed and compact is *perfect*. The continuum, the aggregate of all real numbers, is perfect.

An idea of dominating importance in the theory of functions is that of the *content* or *measure* of a set of points. Suppose, for simplicity, that the set S in question is contained in $(0, 1)$. Then Cantor defined the content of S as follows:—Divide $(0, 1)$ in any manner into a *finite* number of intervals δ, and these intervals δ into two classes δ_1 and δ_2, according as they do or do not include points of S; and let $c(\delta)$ be the sum of the lengths of the intervals δ_1. Then the *content* of S is the limit of $c(\delta)$ when the intervals δ tend to zero, if this limit should exist.

There is a striking defect in this definition, the full implications of which were first perceived by E. Borel. *The content of the sum of two sets is not generally the sum of their contents.* Thus the rationals of $(0, 1)$ have content 1 (since every δ is obviously a δ_1), and likewise the irrationals. The sum of the contents is 2, whereas the content of the sum is 1. The rationals of $(0, 1)$ cannot be included in a finite set of intervals whose aggregate length is less than 1. If we abandon the restriction that the set of intervals must be *finite*, the situation is completely changed. Thus Borel observed that we may include the rational p/q in the interval $\left(\frac{p}{q}-\frac{\epsilon}{q^3}, \frac{p}{q}+\frac{\epsilon}{q^3}\right)$, and that the sum of all these intervals may be made as small as we please by choice of ϵ; and this simple remark has revolutionised the theory of functions. The first step was to frame a satisfactory definition of *measure*, and this concept, which has entirely superseded Cantor's " content," is now defined as follows. We consider sets S included in $(0, 1)$. Let S be enclosed, *in any manner whatsoever*, in a system σ of intervals δ; let $m(\sigma)$ be the sum of the intervals of σ; and let m_e be the lower bound (or " inferior limit ") of the aggregate of values of $m(\sigma)$. Then m_e is the *exterior measure* of S. The *interior measure* m_i is $1-m'_e$, where m'_e is the exterior measure of S_1, the set complementary to S, *i.e.*, the set of points of $(0,1)$ which do not belong to S. If $m_e=m_i$, the set S is *measurable*, and its measure is m, the common value of m_e and m_i. This definition (due to H. Lebesgue) is of extreme generality, and no example of a non-measurable set is known.

Measure, thus defined, has the properties which measure ought to have, but which Cantor's content lacked. In particular the sum of two mutually exclusive and measurable sets is measurable, and its measure is the sum of the measures of the component sets. The measure of any enumerable set, and in particular of the rationals, is zero. The definition may be extended to sets in space of any number of dimensions.

2. *Integration.*—The new theory of measure has led to new theories of integration, in the light of which the older theories are of historical or didactic interest only. The most important of these theories are due to H. Lebesgue and W. H. Young.

(*a*) Lebesgue's definition of an integral is as follows. A function $f(x)$, defined in an interval (a,b), is *measurable* if the set of points $S(A)$ for which $f>A$ is measurable for every A. All known functions are measurable. We now suppose that f is bounded, so that (say) $h<f<H$, and we divide up the interval (h, H) into a finite number of intervals (l_i, l_{i+1}) or δ_i. It is this subdivision of the range of variation of $f(x)$, instead of (as in the older theory) that of x, that is characteristic of Lebesgue's procedure. The set of points for which $(l_i \leqq f < l_{i+1})$ is measurable. If we denote its measure by m_i, write $J = \Sigma l_i m_i$ and suppose that the intervals δ_i tend to zero. Then J tends to a limit I, and we write

$$I=\int_a^b f(x)dx$$

The integral so defined is a *bona-fide* generalisation of the integra of Riemann, for it exists whenever Riemann's integral exists and agrees with it in value. But it is far more general: thus the function $f(x)$ which is unity when x is a rational of $(0,1)$, and zero otherwise has no Riemann integral, but has a Lebesgue integral equal to zero The definition is capable of many-sided generalisation, to unbounded functions, and functions of many variables; it throws entirely new light on the relations between integration and differentiation; and it has proved itself adapted for a mass of analytical applications of the most far-reaching importance, in particular in the theory of Fourier's series and the theory of integral equations.

(*b*) A different definition was proposed by W. H. Young. He adheres to a subdivision of the range of variation (a,b) of the independent variable; but, instead of dividing it into a finite number of intervals, divides it into a finite or infinite number of measurable sets This procedure leads to results roughly equivalent to those of Lebesgue's theory; but it is somewhat more general and is certainly a more natural development of the older theory of measure.

3. *Geometrical Applications.*—Those new theories have led inevitably to a searching re-examination of the concepts of " curve," " surface," " length," " area," and so forth, which were generally accepted without question by the older analysts on the supposed evidence of geometrical intuition. This unreflective attitude has now been abandoned, and it is recognised that analysis is in no sense dependent upon geometry. The notion of a *curve* was first made precise by C. Jordan. A curve is a set of points (x,y), that is an aggregate of pairs of real numbers x, y, where x and y are functions of a single variable t, subject to appropriate restrictions. A simpl closed continuous curve is a curve for which (1) $x=x(t)$ and $y=y(t$ are continuous for $t_1 \leqq t \leqq t_2$; (2) $x(t_2)=x(t_1)$ and $y(t_2)=y(t_1)$, and (3 it is false that $x(t')=x(t'')$ and $y(t')=y(t'')$ for any pair of values t' t'' other than t_1, t_2. A fundamental theorem, due in substance to Jordan, asserts that such a curve C divides the plane into two " regions D and D′ separated by the curve. Two points which lie in the sam region can be connected by a continuous curve which has no point in common with C; but points which lie in different regions cannot be thus connected. We thus define the *inside* and *outside* of a closed curve in strictly analytical terms. A similar account has been given of the concepts of *area* and *length*. In particular the simple closed continuous curve C has both an area and a length if $x(t)$ and $y(t$ are functions of "bounded variation."

4. *Integral Equations.*—Among the remaining developments of modern analysis, perhaps the most remarkable are in the theory of integral equations. The typical integral equation is

$$f(x)=\int_a^b K(x,t)\phi(t)dt \qquad (1$$

where $f(x)$ and $K(x,t)$ are given and the unknown function $\phi(t$ is to be determined. This equation is called an integral equation of the first kind; but it has been found that equations of the form

$$\phi(x)=f(x)+\lambda\int_a^b K(x,t)\phi(t)dt \qquad (2$$

known as equations of the second kind, are better adapted for the foundation of a general theory. It was shown by I. Fredholm that if f and K satisfy certain conditions, there is in general one and only one continuous solution $\phi(t)$; the exceptions arise when λ is a zero of a certain transcendental function $D(\lambda)$. When λ has one of these exceptional values, the equation

$$\phi(x)=\lambda\int_a^b K(x,t)\phi(t)dt$$

has a continuous solution other than the obvious solution $\phi(t)=0$ otherwise this is the only solution. The theory has been widely developed by Fredholm, D. Hilbert, V. Volterra and other writers

MATHEWS, SHAILER (1863–), American educationist and theologian, was born at Portland, Me., May 26 1863. He graduated from Colby College (A.B., 1884; A.M., 1887) and continued his studies at Newton Theological Institution and the University of Berlin. He was associate professor of rhetoric (1887–9) and rofessor of history and political economy (1889–94) at Colby College. In 1894 he went to the University of Chicago as associate rofessor, and in 1897 became professor of New Testament his- ory and interpretation. In 1908 he was made dean of the ivinity school. In 1912 he was president of the Federal Council f the Churches of Christ in America, and he visited Japan in 1915 s representative of that body. From 1903 to 1911 he was editor f *The World Today;* from 1913 to 1920, of *The Biblical World.*

He has written a number of books including *The French Revolution* 1901); *History of New Testament Times in Palestine* (1908); *Social Teachings of Jesus* (1910); *Spiritual Interpretation of History* (1916); nd *Faith of Modernism* (1924). (*See* BAPTISTS.)

MATISSE, HENRI (1869–), French painter, was born at ateau (Nord) Dec. 31 1869. He studied at the École des eaux-Arts, and under Gustave Moreau. He soon showed revo- utionary tendencies, and was recognised as the boldest member f the group known as “ les fauves.” Though a painter of light, e did not treat it as the impressionists had done, by means of he juxtaposition of minute touches of colour, but by employing ure tones on a large scale. In this way he produced the effect f modelling, and, by the contrast of values, was able to give the lusion of space. He was particularly successful in his use of xpressive distortion. Matisse spent two years in Morocco, but ost of his work was carried on in southern France, at Collioure nd Nice. Later, he reduced the size of his canvases, painting ill life and landscapes, as well as small feminine figures and rilliantly illuminated interiors. He is entitled to be considered s the most eminent master of the contemporary French School. n his drawing he exhibits sometimes a nervous restrained man- er, and by his use of shadow succeeds in reproducing the actual ulk of bodies without having to insist on their contour. Ma- sse's lithographic work is also of considerable importance.

BIBLIOGRAPHY.—É. Faure, *Henri Matisse* (1920); Marcel Sembat, *enri Matisse: trente reproductions précédées d'une étude critique* 1920); A. Basler, *Henri Matisse* (1924).

MATSUDAIRA, TSUNEO (1877–), Japanese diplomat, as born in Tōkyō. He joined the Imperial University of Tōkyō s a student of economics, and in 1902 he entered the Foreign ffice. His first experience abroad was gained in Peking where e was a secretary of legation. His determination, however, oupled with his wide theoretical knowledge, pushed him for- ard until he became first secretary in London and later in aris; but his criticism of the extreme nationalism of many his countrymen stood in the way of his receiving imperial onours. From 1918–9 he was Japanese high commissioner in beria and in 1920 was appointed director of the bureau for uropean and American affairs at the Foreign Office in Tōkyō. 1921–2 Matsudaira was chief secretary of the Japanese dele- tion to the Washington Conference. In 1924, after the dip- matic blunder committed by the Japanese Ambassador to e United States, Mr. Hanihara, it was considered that some eans must be found to improve the situation. As a result, in 25 Matsudaira was appointed ambassador and he undertook s duties with the avowed intention of bettering American- panese relations.

MATSUKATA, MASAYOSHI (1835–1924), Japanese statesman *e* 17.890), was from 1917–22 keeper of the privy seal, and on signing from this post was created a prince. He died in Tōkyō ly 2 1924.

MATTEI, TITO (1841–1914), Italian musician and composer, as born at Campobasso, near Naples, May 24 1841. He became an early age a professor at the Santa Cecilia academy of music Rome, and subsequently had several successful European urs as a pianist. In 1863 he finally settled in London, where he mained for the rest of his life. He composed several hundred ngs and pianoforte pieces, many of which became very popular. e died in London March 30 1914.

MATTER (*see* 17.891).—Since 1910 advances have been made hich give much more precision to our knowledge of the consti- tion of matter. The atomic theory of matter, which for long peared to be of necessity unverifiable by direct experiment on count of the minuteness of the atom (*q.v.*), received almost direct proof in a number of ways. Methods have been developed, for example, to detect the electrical effect of a single α particle from radium, and a single swift electron (*see* GASES, ELECTRICAL PROPERTIES OF).

The α particle has been shown to be a charged atom of helium projected with high velocity; the number of α particles from a given quantity of radium have been counted, and the volume of helium which they produce has been measured. In this direct way it has been shown that about $2\cdot7\times10^{19}$ particles or atoms of helium are required to form one cu. cm. of helium gas at normal pressure and temperature. Not only is it feasible to detect the effect of a single atom of matter in special circumstances but also to show the path of a swift α particle or electron through a gas. This has been made possible by the discovery of C. T. R. Wilson that under suitable conditions the charged ions produced in gases by α or β rays become centres for the condensation of water vapours, and are thus rendered visible as the nuclei of visible drops of water. The photographs of these droplets show in a most striking way the track of the particle through the gas, and illustrate with extraordinary detail the main effects produced by the passage of ionising radiations through gases.

The essential correctness of the kinetic theory of matter, which assumes that the molecules of matter are in vigorous but irregular motion, has been clearly demonstrated by the experiments of Perrin and others on the motion and equilibrium of small spheres of matter in suspension in fluids which show the Brownian movement. At the same time the atomic or discrete nature of electricity, which had been implicitly assumed in many theories, has received complete experimental verification, and the magnitude of this fundamental unit of charge has been measured with precision. The most accurate experiments on this subject have been made by Millikan by measuring the electric field required to support a small, charged droplet of oil or mercury. The charge on the drop was varied by ionizing the gas in its neighbourhood. In this way he has been able to show that the charge always varies by integral multiples of a fundamental unit. The charge given to a drop by friction or any other method is always an integral multiple of this unit charge. This fundamental unit is the same both for positive and negative electricity, and is numerically equal to the charge carried by the negative electron, the positive and negative ions produced in a gas by X-rays, and also to the positive charge carried by the hydrogen atom in the electrolysis of water. The magnitude of this unit charge, combined with electrochemical data, gives a most reliable method of measuring a number of important and molecular magnitudes. The value of the fundamental unit of charge and thus the mass of the individual atoms of matter are now known with an accuracy of certainly within one per cent and possibly within one-tenth of one per cent. The data found by Millikan are given in the following table:—

Fundamental unit of charge .	$e=4\cdot774\times10^{-10}$ electrostatic units
The Avogadro Constant, *i.e.*, the number of molecules in one gramme molecule	$N=6\cdot062\times10^{23}$
The number of molecules per c.c. of any gas at 0°C. and 760 mms.	$n=2\cdot705\times10^{19}$
Mass of hydrogen atom in grammes	$m=1\cdot662\times10^{-24}$

From these data the number of atoms in one gramme of any element can be determined. While the average distance apart of the atoms or molecules can at once be deduced, the actual dimensions of the molecules or sphere of action of the molecules can only be approximately estimated with the aid of other and much less precise data.

Structure of the Atom.—Since the proof that the negative electron of small mass is a constituent of all atoms of matter, there has been a vigorous attack on the fundamental problem of the structure of the atom. After passing through a number of phases the general ideas on this subject have crystallized into a fairly definite form, and it is now generally believed that the atom is composed of a massive positively charged nucleus of minute dimensions surrounded at a distance by a compensating distribution of negative electricity in the form of negative electrons. Since electricity is atomic the resultant positive charge on the nucleus must be an integral multiple N of the fundamental unit of charge e and is given by Ne. In order for the atom to be electrically neutral it must be surrounded by a distribution of N negative electrons. The value of N for each of the atoms is a fundamental constant, for on it depends the magnitude of the electric field surrounding the nucleus and the arrangement of the external electrons which in turn determine the main physical and chemical properties of the atom. The idea of the nuclear structure of atoms arose initially from a study of the scattering of α particles in their passage through matter. On account of its great energy of motion the charged α particle penetrates the structure of some of the atoms and comes under the influence of the intense repulsive field of the nucleus. Assuming that the law of force is that of the inverse square the α particle describes a hyperbolic path, and the angle of deflexion depends on the nearness of approach to the nucleus. From a close study of the scattering of α rays by Geiger and Marsden it was concluded that the number of α particles scattered through different angles was in close accord with the idea of the nucleus atom, while the actual number scattered through a given angle gave information on the magnitude of the charge carried by the nucleus. The preliminary experiments indicated that for the heavier atoms the value of N was about half the atomic weight in terms of hydrogen.

A notable advance was made by the fundamental experiments of Moseley on the X-ray spectra of the elements. He found that the X-ray spectrum was similar for all elements, and that the frequency of vibration of corresponding lines in the spectrum was proportional to the square of a number which varied by unity in passing from one element to the next. He concluded that the nuclear charge in fundamental units was equal to the atomic or ordinal number of the elements when arranged in increasing order of their atomic weights. On this view the lightest element, hydrogen, has a nuclear charge 1, helium 2, lithium 3, and so on up to the heaviest element, uranium, of ordinal number 92. This is a generalisation of great importance and simplicity which has guided all subsequent work on the structure of atoms. The essential correctness of Moseley's conclusion has been directly verified in the case of a few representative elements, by Chadwick by accurate measurement of the nuclear charge based on the scattering of α rays. Moseley showed that with few exceptions all values of the nuclear charge between 1 and 92 were represented by known elements. Moreover, when the atomic weight of the element in Mendeleeff's classification was replaced by its ordinal number certain irregularities were removed. For example, the positions of argon and potassium cobalt and nickel, iodine and tellurium were interchanged—a result in complete accord with their chemical properties (*see* CHEMISTRY).

The elements missing in the Moseley classification were of atomic numbers 43, 61, 72, 75, 85, 87. Since the X-ray spectra of these elements could be calculated with accuracy, it seemed likely that these missing elements, if present in appreciable quantity in the earth's crust, should soon be detected. The first element discovered by its X-ray spectrum was number 72 which was called hafnium by Hevesy and Coster. In a similar way, elements of number 43, 75, have been recently found in certain platinum minerals by Nonnack and Tacke, but have not yet been isolated. Thus the number of missing elements from hydrogen to uranium is reduced to three, viz., numbers 61, 85, 87.

It thus follows that the main physical and chemical properties of an element are defined by a whole number which represents both its nuclear charge in fundamental units and the number of external electrons. The atomic weight of an element is in a sense a secondary property, for, as we shall see, elements can exist of the same nuclear charge but of different atomic weights. The number and position of the external electrons, on which the ordinary chemical and physical properties of an atom depend, are defined by the nuclear charge. The mass of the atom which resides mainly in the nucleus exercises a subordinate effect on the external arrangement of the electrons.

Isotopes (*q.v.*).—On Moseley's classification only 92 elements of ordinal numbers 1 to 92 are possible, assuming that uranium (92) is the last of the elements. We shall now briefly discu some recent advances which clearly show that in some cas several elements can exist with the same nuclear charge but different atomic masses. Information on this point was first ob tained from a study of the radioactive bodies. It was early ob served that a number of products which showed different radi active properties were inseparable from one another by ordinar physical and chemical methods. For example, ionium and tho ium, radium and mesothorium, radium D and lead cannot b separated from each other, and appear to be identical in chemic properties. Elements so closely alike in chemical properties we called "isotopes" by Soddy, since they appeared to occupy th same position in the periodic arrangement of the element Viewed from the standpoint of the nuclear theory isotopes a elements of the same nuclear charge but of different atom masses. As we have seen, the nuclear charge controls the ord nary physical and chemical properties of the atom, and the mas which resides almost entirely in the nucleus has only a secon order effect. On the other hand, the property of radioactivit depends on the structure and stability of the nucleus, which ma be very different for atoms of the same resultant nuclear charg

In the article on RADIOACTIVITY attention is drawn to th remarkably simple relation which exists between the chemic properties and radiations of the series of radioactive element With the aid of this relation we can at once write down the ord nal numbers and masses of the long series of elements whic arise from the transformation of uranium, thorium and actiniu and can follow the origin of the numerous isotopes which aris One of the most striking results of this generalisation was the prediction that the end product of the uranium and thorium serie should be an element of the same ordinal number as lead but c atomic masses 206 and 208 respectively, instead of the mass 20 found for ordinary lead. This result has been directly confirme by atomic weight determinations of uranium-lead and thorium lead, and was the first definite proof of the existence of isotope of a non-radioactive element.

It seemed probable that in a similar way many of the ordinar elements might consist of a mixture of isotopes, *i.e.*, element with the same nuclear charge but different atomic masses. Thi has been confirmed in a number of cases chiefly by the work c Aston. The masses of the positively charged atoms present i the electric discharge in a vacuum tube are examined by bendin the rays in a combined magnetic and electric field. In this wa it was found that neon consisted of two isotopes of masses 20 an 22 and chlorine of isotopes of masses 35 and 37. The relativ proportions of the two isotopes in chlorine was in good accor with that to be expected from the ordinary atomic weight of th mixture of isotopes, viz., 35·45.

This new method of analysis had, up to 1925, been employe for more than half of the elements and had yielded results o great interest. Some of the elements, like carbon, nitrogen an oxygen, give no isotopes, and are thus to be regarded as "pure" elements where the atoms have all the same mass and nuclea charge. Others, like chlorine, argon, krypton and mercury, ar composed of a mixture of two or more isotopes. In cases lik krypton and mercury as many as six well-defined isotopes hav been detected. With few exceptions the masses of all the isotopes are expressed by a whole number in terms of O=16 wit an accuracy of about 1 in 1,000. For example, the isotopes o neon are 20·00 and 22·00. This important conclusion, which ha been verified in a number of cases, affords a strong indicatio that the masses of the parts composing the nucleus have a mas either of one or a multiple of one, and are not direct multiple of the mass of the hydrogen atom which is 1·008 where O=16 The reason of this will be discussed later. In a few cases, however, for example tin and xenon where the isotopes can be obtained together on the same record, Aston has pointed out tha the whole-number rule obviously breaks down. It will be o great importance to determine the mass of all the isotopes wit the greatest exactitude as the departure of the masses fron whole numbers may provide valuable information on the structure of atomic nuclei.

While the ordinary physical and chemical properties of iso- pes are closely similar, it is to be expected that they should fer in all qualities which involve directly the mass of the atom, ., the coefficients of diffusion and specific gravity. In a similar y second-order effect is to be expected in the rate of vibration the external electrons, *i.e.*, in the light spectrum of the ele- ent, and a small effect has been observed in several cases. The ost obvious method of partial separation of isotopes is by the ocess of diffusion or evaporation. In this way a partial sepa- ion into light and heavy fractions has been shown in the case neon, mercury and chlorine. No evidence of the separation isotopes in nature has been so far observed except in the case uranium-lead and thorium-lead already referred to. For mple, chlorine obtained from widely different sources shows difference in the relative proportions of its component isotopes.

Distribution of Electrons.—We have seen that the atom is to regarded as an electrical structure in which a positively arged nucleus is surrounded by a number of electrons. The gnitude of the nuclear charge and the number of the external ctrons are known for each of the elements. In considering distribution of the external electrons round the nucleus, we at the outset faced by the great difficulty that no possible angement can be permanently stable on the basis of the class- l dynamics. For example, an electron in motion round the cleus must on the classical theory radiate energy and fall into nucleus. To overcome this fundamental difficulty Bohr has roduced a conception, based on the quantum theory (*q.v.*), which radiation only occurs in definite quanta. This concep- n further developed by Sommerfeld and others has been al- st completely successful in describing the properties of the plest atom (hydrogen) with only one electron. It yields not y its natural frequencies but also the detailed changes which y undergo under the influence of electric and magnetic fields. n atoms with more than one electron, success has so far been complete. This is probably not entirely due to the mathe- tical difficulties of the classical problem of three or more at- cting bodies (almost insuperable as these are) but even more deep seated inadequacies in the modifications of classical ory required by atomic theory. The simple modifications roduced by Bohr with success for hydrogen await further elopment. In spite of this, however, the theory in its present n has already won marked successes. It has accounted suc- fully for the general structure of the spectra of all atoms and ir resemblances to the spectrum of hydrogen, for the general ngement and actual magnitudes of their X-ray spectra, and the close analogies which these exhibit to optical spectra. as enabled the grouping of the electrons in all atoms to be ermined, with rough estimates of the size of the orbits to ch they are confined. The later developments of the theory in-Smith, Stoner) seem to present the details and subgroups lectrons in the atom with some approach to finality, in har- ny with all the physical and chemical evidence.

he theory has succeeded in accounting naturally for the form he periodic table of the elements, especially the occurrence of transition groups of elements ending at copper, silver and l, and for the occurrence of the chemically similar rare-earths. as therefore already played a great part in the simplification co-ordination of facts of value. Its developments seem likely upersede suggestions as to the grouping of the electrons in atom which have been advanced previously from time to e—notably by Kossel, Lewis, Langmuir, J. J. Thomson, certain measures of success in explaining the periodic table he elements and the methods of chemical combination. These ier theories were, however, for the most part descriptive er than qualitative in character—to a far greater extent the theory initiated by Bohr. The whole problem of the ribution and motion of the electrons in a complex atom is a difficult one. While definite progress had been made by , and great advances between 1921 and 1925, much still ains to be done before we can hope to specify with any degree uantitative completeness the motion, position and mode of ation of the electrons in any atom of two or more electrons.

Structure of the Nucleus.—While it is difficult to estimate the dimensions of atomic nuclei, the general evidence indicates that the nucleus of a heavy atom like uranium, if assumed spherical, has a radius of less than 10^{-11} cm. or less than 1/1000 of the radius of the external atom. No doubt the dimensions of a nucleus depend on its complexity and are much smaller for the lighter atoms. From experiments on the passage of α particles through hydrogen, it has been calculated that the dimensions of the helium nucleus of mass 4 is of the order 10^{-12} centimetres.

The most direct evidence on the constitution of the nucleus is derived from the study of the radioactive transformations. The disintegration of an atom is accompanied either by the expulsion of an α particle, *i.e.*, in helium nucleus, or the release of a swift electron from the nucleus. This shows that the nucleus of the radioactive atoms contains both positively charged masses and negative electrons, and that the nuclear charge represents the resultant charge. It is natural to conclude that the helium nucleus of mass 4 is one of the secondary units which make up the structure of a complex nucleus. This is supported by the observation that the atomic mass of many atoms is expressed by 4^n where n is a whole number. It is clear, however, from the work of Aston on isotopes that, in addition to the helium nucleus, an element of mass 1 or integral multiple of 1 enters into the structure of all nuclei. This fundamental unit of structure has been named "proton," and its atomic mass is 1 or very nearly 1 in terms of $O=16$. On this view the nuclei of all elements are made up of positively charged protons and electrons. The mass of the atom measures the number of protons in the nucleus. This is in a sense a return to the famous hypothesis of Prout according to which all the atoms are supposed to be built up of hydrogen as the fundamental unit.

It seems clear that if a proton could be removed from an atomic nucleus it would prove to be the hydrogen nucleus carrying a unit positive charge. In fact, Rutherford and Chadwick have shown that the hydrogen nucleus can be liberated from certain light atoms by bombardment with swift α particles. It remains, however, to explain why the proton in a nucleus has a different mass from the free hydrogen nucleus. The latter has a mass 1·008 in terms of $O=16$ while the proton in the nucleus has a mass unity, or nearly unity.

While the negative unit of electricity exists in the form of the electron of very small mass, no evidence has been obtained that its counterpart, the positive electron of very small mass, exists. The unit of positive electricity has never been found to be associated with a mass less than that of the hydrogen atom. This has led to the view that the hydrogen nucleus is the *positive* electron, and that its mass is about 1,845 times that of the negative electron. This difference in mass between the units of positive and negative electricity appears to be fundamental, and offers an explanation of the asymmetrical distribution of positive and negative electricity in the structure of atoms.

Since the helium nucleus has a mass 4 and charge 2, it should be composed of four hydrogen nuclei and two electrons. Its mass, however, is less than that of four free hydrogen nuclei. Such a change of mass in the very close combinations of positive and negative nuclei is to be expected. According to the theory of relativity energy has mass, and the loss of mass m of a system is numerically given by $E=mc^2$ where E is the energy liberated and c the velocity of light. On this view the combination of the positive and negative electrons to form the helium nucleus is accompanied by a large release of energy. From the difference between the mass of the helium nucleus and that of four hydrogen nuclei, it can readily be calculated that the helium nucleus is such a stable combination that an amount of energy corresponding to four or five α particles from radium would be required to dissociate it. The difference between the masses of the protons in the nucleus and free hydrogen nuclei is thus to be ascribed in general to the close packing of the positive and negative units composing the nucleus.

On the views outlined above the number of electrons in any nucleus can at once be calculated. For example, oxygen of nuclear charge 8 should be made up of 16 positive units and 8 electrons. For such a nucleus to hold together it seems clear that the forces between the charged units at such small distances must be different from that of the inverse square. While it has been experimentally shown that the law of the inverse square holds at any rate approximately close to the nucleus of a heavy atom like gold, this law breaks down in very close collisions of light atoms where the nuclei approach very close to each other. For example, it has been found that the number of hydrogen atoms which are set in swift motion when α particles pass through hydrogen is very different from that to be expected if the nuclei behave as point charges repelling each other according to the law of the inverse square.

By studying the scattering of α particles by the light elements, aluminium and magnesium, it has been found that the law of the simple inverse square no longer holds close to the nucleus. The experimental information at present available is too indefinite to hazard more than a guess as to the nature and magnitude of the forces that come into play when nuclei approach very close to one another, as they must do in the structure of the nucleus of a heavy atom.

Stability of Atoms.—Apart from the heavy radioactive elements which belong to a class by themselves, and two other elements—potassium and rubidium—which spontaneously emit swift electrons, the atoms of the ordinary elements appear to be very stable structures which cannot be broken up by ordinary chemical and physical agencies. In considering the possibility of the disintegration of elements it should be borne in mind that the loss of one or more electrons from the outer electronic system has no permanent effect on the atom, for other electrons ultimately fall into the atom to fill their place. In order to produce a permanent transformation of the atom it appears necessary to remove a positively charged particle or an electron from the nucleus of the atom. This can only be effected by agencies which are able to penetrate the nucleus or to pass very close to its structure.

A number of experiments have suggested that possibly helium and hydrogen may be liberated by the passage of an electric discharge through gases, but on account of the presence of these elements in many materials it is difficult to prove definitely that they arise from artificial transformation. During the last few years there has been a vigorous attack on the question whether transformation of nuclei can be effected by the action of intense electric discharges through gases or vapours. By passing a heavy current through mercury vapour, it is claimed that gold is produced in appreciable quantity. By a similar mode of procedure it is stated that lead can be converted into mercury. For obvious reasons, it is very difficult to be certain that the elements observed were not originally present in some form in the material subjected to the electrical discharge. In the cases mentioned above, we should have expected that the gold or mercury would have a different atomic weight from ordinary gold but definite evidence on this point is not yet available. The whole question whether transformation of atomic nuclei can be produced in such a comparatively simple way and on such a large scale is still *sub judice.* The energy of the electrons in the discharges used is in general small compared with that of the α particle, with the aid of which transformations on a minute scale were first shown.

The α particle expelled from radium is one of the most concentrated sources of energy known to us, and on account of its speed should be able to penetrate the structure of the nuclei of many of the lighter atoms, and still retain sufficient energy to disrupt the bonds that hold the parts of the nucleus together. In the case of an atom of high nuclear charge the α particle may lose so much of its energy in approaching the nucleus that it may be unable to effect its disintegration. It has been found that when α particles pass through hydrogen or any material containing combined hydrogen, some of the particles pass so close to the hydrogen nucleus that they set it in swift motion. These swift hydrogen atoms can be detected by the scintillations they produce on a zinc sulphide screen. This is purely a case of collisions of atomic nuclei, and the speed of the H atom set in motion can be calculated by the ordinary laws of mechan The maximum range or distance of penetration of such a part is about four times that of the incident α particle.

In a similar way other nuclei must be set in swift motion their collision with α particles, but it can be calculated that most cases such nuclei are unable to travel as far as the α pa cle, and thus remain undetected amid the great number of i dent α particles.

Rutherford showed that when a strong beam of α partic passes through oxygen or carbon dioxide, only a few H atoms a penetrating type are present and these appear to have th origin in the radioactive source. When, however, the rays p through dry nitrogen, a much larger number of penetrat particles is observed. By bending these particles in a magne field, it is clear that these swift particles are not charged ato of nitrogen but projected hydrogen nuclei. These H partic are detected by the scintillations they produce in falling o screen of zinc sulphide, and progress in this line of work has b much facilitated by the designing of special counting microsco of wide aperture which have a large field of view. Rutherf and Chadwick found that in addition to nitrogen, swift H pa cles are liberated from boron, flourine, sodium, aluminium a phosphorus. By a variation in the method, similar H partic but of lower speed, were observed from neon, magnesium, s con, sulphur, chlorine, argon and potassium. Kirsch and Pett son claim that H particles are also liberated from carbon a oxygen, but this question is still *sub judice.*

It seems clear that these H particles are liberated from nuclei of these elements by the bombardment of α particles a in a sense we may say that these nuclei have undergone a nucl transformation with the ejection of a proton at high speed. I elements like B, N, Na, Al, P, the velocity of expulsion of the particles is in all cases greater than that for a free H atom i close collision with an α particle. For example, using α partic of range 7·0 cm. in air, ordinary H atoms can not travel furt than 30 cm. of air. On the other hand, the H particles liberat from nitrogen travel 40 cm. and from aluminium 90 cm. It thus certain that H particles observed from the elements giv above cannot be due to the presence of ordinary hydrogen an impurity. In the case of aluminium, a few of the H partic are released with more energy than that of the α particle whi effects their release. No certain evidence has yet been observ that other types of particles are set free in these disintegrati collisions. It might have been expected that nuclei of mass 2 3 or 4 should also appear in some cases, as there is some eviden that secondary units of this kind go to build up atomic nuclei.

It is of interest to note that the protons set free by the α p ticles appear to be ejected equally in all directions, although th speed is somewhat greater in the forward direction of the α p ticle. This difference is no doubt due to the fact that the bo barded nucleus is set in motion by the collision.

It is difficult to be certain of the mechanism of these collisio and in particular whether the bombarding α particle is captur by the nucleus when the proton is liberated. By photographi several hundred thousand tracks of α particles in nitrogen by t Wilson method, Blackett has observed a number of collisio involving the escape of a high speed proton. There is, howev no trace of the α particle after the collision, indicating that it captured by the nucleus. If this be the case, the nucleus gai an α particle of mass 4 and loses a proton of mass 1. No defin evidence of the mechanism of the collision is as yet available f the other "active" elements.

It should be borne in mind that the disintegration observed this way is on an exceedingly small scale. Not more than particles in a million get sufficiently close to a nucleus to relea an H atom. It seems clear, however, that while the ordina atom is undoubtedly very stable, its disintegration can be broug about by the aid of sufficiently powerful agencies which are ab to penetrate its structure. As already pointed out, there a strong reasons for believing that the helium nucleus is a ve stable structure which cannot be broken up even by the swifte α particle at our disposal.

While it is reasonable to suppose that all the elements have een built up by combinations of protons and electrons, there as in 1925 little evidence to throw light on the conditions neces- ary to lead to the formation of complex nuclei. No doubt, how- ver, this process of aggregation has gone on in the past, and may ill be in progress under favourable conditions, if not on this arth, at any rate in some of the stars. (E. Ru.)

MAUDE, SIR FREDERICK STANLEY (1864–1917), British oldier, son of Gen. Sir Frederick Maude, V.C., was born at ibraltar June 24 1864. He entered the Coldstream Guards in 84, took part in the Suakin operations, 1885, and joined the aff College in 1895. In the South-African War, as brigade- ajor of the Guards Brigade, he took part in the advance to retoria. After a spell in Canada as military secretary to the overnor-general, he took an active part in the development of e organisation and training of the new Territorial Force. On obilisation in Aug. 1914 he was posted to the staff of the III. rmy Corps and served in France until June 1915. In Aug. he as hurried out to the Dardanelles to take up command of the th Division. There he played a conspicuous part in the evac- tions of Suvla and of Helles, and in 1916 his division was dis- tched from Egypt to Mesopotamia to aid in the relief of Kut- -Imara. They arrived in time to bear a share in the final esperate endeavours to save the doomed stronghold, but the ort came to naught and after the surrender of Kut-al-Imara, aude and his division remained facing the Turks on the Tigris. e was advanced in Sept. to the position of army commander Mesopotamia.

Realising that victory in this theatre of war must hinge on ective organisation and adequate preparation, Maude spent ree months at Basra, ensuring that when the time came his ld army should be capable of acting with vigour and decision. en, when all was ready early in Dec., he suddenly pushed rward and within a few weeks had driven the Turks in con- sion out of their entrenched camp around Kut. Moving re- tlessly on, and making great captures, he occupied Baghdad arch 11. He spent the next few months consolidating his sition and preparing plans for a fresh offensive. He was, wever, struck down by cholera, and died at Baghdad Nov. 18 17. His conquest of Mesopotamia and his transformation of a pressing situation into one of signal triumph ranks as one of e finest feats in modern military history. (*See* MESOPOTAMIA, ERATIONS IN.) See Maj.-Gen. Sir C. E. Callwell, *Life of Sir nley Maude* (1920).

MAUNOURY, MICHEL JOSEPH (1847–1923), French soldier, s born at Maintenon (Eure-et-Loir) Dec. 11 1847. Com- ssioned to the artillery from the École Polytechnique in 1869, saw service in the Franco-German War, and in 1883 was ced on the staff at the military school of St. Cyr. He retired 1912, having been military governor of Paris and a member the Conseil Supérieur de la Guerre. On Aug. 19 1914 he was en charge of the army improvised in Lorraine from the erve divisions, and was entrusted with the investment of tz. On Aug. 24 he made a brilliant attack on the left flank he V. German Army; and when, on Aug. 26, a new VI. Army s assembled on the Somme, the command was given to Gen. unoury. It was this army, which, on Sept. 4, was launched inst the flank of Von Kluck's I. Army—an action which opened exercised a decisive influence on the battle of the Marne. unoury continued to command the VI. Army throughout development of the Aisne line of battle and in the early ses of trench warfare. On March 15 1915 he was severely nded, and thereafter held no active command. From v. 1915 till March 1916 he was Governor of Paris. He died March 28 1923 and was created marshal of France post- nously.

AURA, ANTONIO MONTANER (1853–1925), Spanish states- , was born in Palma de Mallorca May 2 1853. He was cated at Valencia and Madrid where he studied law. Though pronunciation of Spanish was first defective, by perseverance force of personality he became in later years a great forensic parliamentary orator. Elected deputy for his native city in 1881, he joined the Liberal party; but his instincts were conservative and in 1901 he went over to the Conservative party of which he eventually became leader. He was a constructive statesman, and though the chaotic state of the Spanish political fabric inspired in him a desire for reform, he always regarded the constitution as sacred. In 1903 he became Prime Minister, and his zeal for reform made him many enemies among the corrupt political factions of Spain. He negotiated with France on the subject of Spanish rights in Tangier and Morocco and with Great Britain concerning the *status quo* of the seas. In 1913 he resigned the leadership of the Conservative party, but, in response to appeals from the king, he formed governments in 1918, 1919 and 1921. True to his constitutional ideals, he refused to make common cause with the Directorate of 1923 which superseded parliamentary government in Spain. He died Dec. 13 1925.

MAUREL, VICTOR (1848–1923), French singer (*see* 17.907), died in New York Oct. 23 1923.

MAURICE, SIR FREDERICK BARTON (1871–), British soldier, was born Feb. 1 1871, and was commissioned in the Sherwood Foresters (Notts. and Derby Regiment) in 1892. He saw service in the Tirah campaign 1897–8 and the South African War 1899–1900 and from 1904 until 1914 held a series of general staff appointments, the last year as instructor at the Staff College. On the outbreak of the World War he was appointed General Staff Officer (1st grade) to the 3rd Div., British Expeditionary Force. He became brigadier-general, general staff, in 1915 and the same year he was advanced to the post of Director of Military Operations at the War Office. Here he was, during the middle period of the War, the intimate and valued assistant of Sir William Robertson, until the latter's resignation early in 1918. After the spring disasters Maurice wrote a letter to the Press challenging the accuracy of ministerial statements, considering them an attempt to shift the responsibility on to the army when several hundred thousand troops were retained in England to guard against a hypothetical invasion. By this act of moral courage he fulfilled his sense of honesty at the sacrifice of his career. Retired for the breach of discipline he became a military correspondent, and after the War, as Principal of the Working Men's College, St. Pancras, London, and Vice-President of the British Legion, was prominent in social work. His publications include *Forty Days in 1914* (1920); *Lord Wolseley* (with Sir George Arthur, 1924); *Robert E. Lee, the Soldier* (1925). (*See* WESTERN FRONT.)

MAURITANIA (*see* SENEGAL, 24.643).—This region of French West Africa, between the Senegal river and Rio de Oro, was constituted a colony in 1921. The area, including Saharan regions, is 154,000 sq. miles. The population, mostly Moors, *i.e.*, tribes of mixed Berber and Arab descent, is 280,000. Port Etienne, on Lévrier Bay, Cap Blanc, created since the occupation of the country by the French, is the seat of a growing fishing industry.

MAURITIUS (*see* 17.912).—A British crown colony in the Indian Ocean, 500 m. east of Madagascar. Its area is 720 square miles. The estimated population at the end of 1923 was 381,678. An influenza epidemic swept the island during the months of May, June, July 1918 when 11,000 persons died, the death-rate in that year reaching the high figure of 64·9 per thousand. Primary education is free but not compulsory. The total number of primary schools in 1919 was 148, of which 57 were Government schools and 91 schools receiving state aid. The number of pupils on the registers was 22,120. Of the state-aided schools 67 were Roman Catholic, 10 Church of England, two Mahommedan and one Hindu. In all schools under government inspection the teaching of elementary hygiene and sanitation is compulsory.

Finance and Trade.—The highest figures for the revenue of the colony were reached during the financial year 1920–1 when the total revenue was rupees 40,168,210; expenditure in the same year was Rs. 24,729,510. Figures for subsequent financial years were:—

	1921–2 Rs.	1922–3 Rs.
Revenue	25,599,994	23,547,734
Expenditure	26,307,658	22,031,176

At the close of the financial year 1923 the public debt of the colony was £1,265,724.

Sugar production remains the principal industry of the colony, the total average under sugar cultivation being in excess of 175,923 acres. A record sugar crop was produced during the crop year 1918–9 when the output of the sugar factories was 252,772 metric tons; the output for 1923–4 was 195,356 metric tons. The production of aloe fibre ranks next to sugar in order of importance; rum, copra, coconut oil are other products that have shown an increase. Increased attention has been given to tobacco growing and the cultivation of tea has progressed. Lectures and demonstrations in modern agricultural methods are given by the Government agricultural instructor. The total trade of the colony reached record figures during 1919 when the combined values for the year were Rs. 174,843,348—imports Rs. 47,037,024, exports Rs. 127,806,321. Imports for 1923 were valued at Rs. 76,835,565 and exports Rs. 69,841,935.

The total mileage of the railways on the island in 1923 was 144 miles. The Mauritius Govt. railway main line gauge is 4 ft. 8½ inches. The short Bois Chéri light railway has a 2 ft. 6 in. gauge. The mileage of telegraph lines in 1923 was 415½ m., and of telephone lines 169¼ miles. Cable communication is maintained with Zanzibar, Australia, Réunion, Madagascar, Durban and other places.

See A. Macmillan, *Mauritius Illustrated* (1914); also *Colonial Office List* (Annual Series, London); *Mauritius Blue Book* (Annual, Mauritius). (H. C. WA.)

MAURRAS, CHARLES (1868–), French writer and politician, was born at Martigues, Provence, of a royalist family. He first became prominent through his literary criticisms in the *Revue Encyclopédique* and the *Gazette de France*. He was at first the only Royalist on the staff of the *Action Française*, but soon converted almost all his colleagues. After visiting Greece and Italy he published *Trois idées politiques* (1898); *Les amants de Venise* (1902); and *L'avenir de l'intelligence* (1905). This was his most productive period, during which his royalist propaganda exerted a powerful influence; he assisted Léon Daudet in transforming the *Action Française* into a daily paper, which took place in 1908, and soon became engrossed in journalistic work. In his *Kiel et Tanger* (1910) he criticised French foreign policy, while *Le dilemme de Marc Sangnier* (1906) dealt with religious problems. Though an avowed atheist, Maurras somewhat paradoxically favoured an alliance with the Catholic Church which he regarded as closely connected with the monarchy. And indeed the *Action Française* lost considerable influence when the French clergy withdrew their support and defeated Daudet during his candidature for Parliament in 1923 and 1925.

During the War Maurras worked for the disintegration of Germany and for an overwhelming victory for France. His war articles appeared in eight volumes entitled *Les conditions de la victoire* (1915–20). Though his polemical writing injured his literary fame, Maurras nevertheless gained the reputation of being one of the most accomplished of modern French authors; and his critical works, such as *L'ètang de Berre* (1915); *Le conseil de Dante* (1920) and *L'allée des philosophes* (1924) are written in restrained but powerful prose. His poems, often of great beauty, were collected in *La musique intérieure* (1925). Though the writings of Maurras produced a profound effect on French thought, his influence on practical politics has been but slight; for his political theories suffer from extremism and exaggeration, both characteristics of his race. His nationalist ideas failed to take deep root in his own country, but they triumphed in Italy; and *L'Idea Nazionale* with its fascist doctrines owed much to the *Action Française*. The French movement with which the name of Maurras is associated may be regarded as an inchoate Fascism; a minor intellectual revolution, which has not developed into any great political upheaval. Among Maurras' many works may be mentioned the following: *Jean Moréas* (1891); *Le chemin de paradis* (1894); *Anthinéa* (1901); *L'enquête sur la monarchie* (1900–9); *La politique religieuse* (1912); *Quand les Français ne s'aimaient pas* (1916).

MAX, ADOLPHE (1869–), Belgian politician, was bo in Brussels Dec. 31 1869. From 1894 to 1903 he was successive provincial councillor of Brabant, councillor of the Commune a alderman of Brussels, and finally burgomaster (1909). In 19 when the German troops entered Brussels he refused to perfor his duties under the authority of the German governor, a demanded complete freedom of action. He protested vigorous against the abuses of the army of occupation, and fought wi indomitable energy for the rights of his fellow subjects, and f the reduction of the heavy taxes and requisitions which we imposed on the town. He further founded a central committee deal with supplies which, under the name of *Le Comité Nation* rendered invaluable services to his countrymen. But the Germ authorities soon took exception to his spirited resistance, a on Sept. 26 1914 he was arrested and imprisoned in the fortre of Namur, and from there was sent into Germany, where he w closely confined. On Nov. 13 1918 he succeeded in escaping a returned to Belgium, where he was welcomed with delirio enthusiasm. M. Max was elected to the Chamber of Represen atives in 1919; he was made minister of state on Nov. 21 191 and was also elected member of the Belgian Academy.

MAXIM, SIR HIRAM STEVENS (1841–1916), Anglo-Americ engineer and inventor (*see* 17.918), died in London Nov. 24 191

MAXIMILIAN (1867–), Prince of Baden, born June 1867 at Baden-Baden, was a son of Prince William of Bade As the nearest agnate to the reigning grand duke, of whom he w a cousin twice removed, he was heir presumptive to the gra ducal throne. From 1907 to 1918 he was president of the Fir Chamber of the Baden Diet. During the War Prince Max d much to improve conditions for British prisoners in German as also for German prisoners, especially in Russia. On Oct. 1918, when the old military and political system in Germany w on the verge of collapse, he was appointed Imperial Chancello It fell to his lot to initiate the negotiations for the Armistice, a also to carry through in hot haste those alterations in the o constitution which had long been demanded by the Liberals a the Socialists, but which now came too late to avert the fate the Empire and the Prussian Monarchy. It also became his dut to put pressure upon the Emperor in order to induce him abdicate. As the Imperial decision was delayed from day to da and the revolution became imminent, he declared on Nov. 1918 the abdication of William II. as German Emperor and King of Prussia. It was clear that the Hohenzollern dynast was doomed; and Prince Max handed over the Government the majority Socialist leader Ebert, who became the presider of the German Reich. He continued, after the abdication of th grand duke, to reside at Karlsruhe. (*See* GERMANY.)

MAXSE, SIR IVOR (1862–), British soldier, was bor Dec. 22 1862 and was commissioned in the Royal Fusiliers i 1882, transferring to the Coldstream Guards in 1891. He serve in the Sudan campaigns 1897–9, during which he gained th D.S.O., and in the Boer War 1899, as staff officer to Mounte Infantry and as commander of the Transvaal Constabular after the capture of Pretoria. From 1902–10 he was regimenta commander of the Coldstream Guards, and on the outbreak the World War he went to France in command of the 1st Guard Brigade, which he led during the retreat from Mons and in th battles of the Marne and the Aisne. In Oct. 1914 he was pro moted to the command of the 18th Division. He brought thi division to France in 1915, and his unique training methods bor fruit in the battle of the Somme, where the 18th Div. obtaine an opening success in brilliant contrast to the fate of othe divisions on the tragic July 1 1916. As a consequence his pro motion to command of the 18th Army Corps followed in Jan 1917, and this he led with distinction down to, and including, th St. Quentin battle in March 1918. In 1917 he was created K.C.B

The British Army was so sorely shattered in resisting th German offensive of 1918 that its reconstruction and trans formation into the irresistible striking force of the autum appears almost a miracle. In the glory of this achievement Si Ivor Maxse has a notable share. The need for a unified direction of training was realised and he was chosen to be inspector-genera training to the British Armies in France. By the development of the new tactics of infiltration and manoeuvre, by the proved co-operation between the different armies, and by new elasticity of tactical handling, his work is engraved in the ounding success and low casualty list of the army during the vance to victory. After the War, at the hand of the Northern mmand 1919–23, Maxse's influence in recasting the training infantry and in making tactics intelligible to the novice was marked as his practical achievement in the reorganisation of depôt system. Dynamic in thought and energy, receptive to as, and generous in his support of youthful ability, he had a ius for training which was reminiscent of the influence of John Moore, a century before. Sir Ivor contributed to this cyclopædia the article INFANTRY.

IAYO, CHARLES HORACE (1865–   ), American surgeon, born at Rochester, Minn., July 19 1865. After studying at Rochester High School, Northwestern University and the cago Medical College (M.D. 1888), he began the practice of gery at Rochester, Minn., and with his brother became sur- at the Mayo Clinic. He made a special study of goitre, as a result succeeded in reducing the death-rate in this class ases by half. He has published a number of papers on surgical cs in medical journals. He was elected president of the nesota State Medical Society in 1905, president of the ical section of the International Tuberculosis Congress in 3, and president of the American Medical Assn. in 1916. He appointed Mayo Foundation professor of surgery in 1915. ing 1917–8 he was president of the examining board of icants for commissions in the Medical Corps, having super- on over several states, including Minnesota. In 1918 he was ointed colonel in the Medical Reserve Corps, U.S.A., and a year was associate chief consultant for surgical service. nning with 1912, graduate courses in medicine were offered he Mayo Clinic in Rochester. Early in 1915 he and his her incorporated the Mayo Foundation for medical educa- and research at Rochester, and to it the brothers gave 00,000. In June of the same year, by mutual agreement, the s and resources of the foundation were placed under the ction of the regent of the University of Minnesota for promot- "graduate work in medicine and research in this field." Sept. 13 1917 the Foundation, with its fully-equipped staff, ratories and clinics in Rochester, became a department of university. (*See* SURGERY.)

AYO, WILLIAM JAMES (1861–   ), American surgeon, was at Le Sueur, Minn., June 29 1861. He was graduated in cine from the University of Michigan in 1883 and began the ice of surgery in Rochester, Minnesota. A small hospital organised under the local branch of the Sisters of St. cis, which developed into St. Mary's Hospital. Here he, his younger brother, Charles Horace, developed the Mayo c (organised 1889), which became famous throughout the l for the number and success of operations performed. The ds of operations have been so carefully and accurately and preserved that they form a valuable asset to medical ce. Though the clinic has contributed no discovery of new ods or new cures for diseases, all modern methods have covered and reduced to their ultimate accuracy. Accuracy een the keynote to the Mayos' success. Goitre, gall bladder, ndix and gastro-intestinal operations constituted the great ity of the cases, and the proportion of deaths to the total er of patients operated upon was remarkably low. Dr. Mayo specialised in the surgery of the stomach, and pub- a large number of papers on gastric surgery and kindred . He was elected president of the Minnesota State Medical y in 1895, and in 1907 was appointed a regent of the Uni- y of Minnesota. He was elected president of the Society for al Surgery in 1911, and the following year president of the ican Surgical Association. On America's entrance into the l War he was appointed a colonel in the Medical Corps, Army, and chief consultant for surgical service, alternating his brother, C. H. Mayo, in this capacity. In 1919 he was led the medal for distinguished service. (*See* SURGERY.)

MAYOR, JOHN EYTON BICKERSTETH (1825–1910), British classical scholar (*see* 17.937), died at Cambridge Dec. 31 1910.

MEAD, LARKIN GOLDSMITH (1835–1910), American sculptor (*see* 17.945), died at Florence, Italy, Oct. 15 1910.

MEASLES: *see* INFECTIOUS FEVERS.

MEASUREMENTS (*see* 18.134).—The science of measurement is in practice restricted to mean measurement of the three fundamental quantities, mass, length and time, from which all other quantities, such for example as volume, density, velocity, acceleration, force and power, are derived. The problem of measurement of these three fundamental quantities presents itself primarily as a question of providing suitable units of reference against which other quantities whose values it is desired to measure may be compared.

Importance of Metrology.—On the purely scientific side all other scientific quantities are ultimately definable in terms of the three fundamental quantities with which metrology deals, and every quantitative determination resolves itself in the last resort into a measurement of one or other of these quantities. If "science is measurement" then without metrology there is no science. Even in its most direct application it covers a very wide field (*see* MENSURATION [15.134]; SURVEYING; GEODESY; EARTH, FIGURE OF THE [8.801]; MICROMETER [15.38]; TOOL, PART 13 [27.43]; MEASURING INSTRUMENTS; TIME [26.983]; CLOCKS [6.536]; WEIGHTS AND MEASURES [25.477]; WEIGHING MACHINES [25.468]; METRIC SYSTEM [15.299]). The question of the time standard, moreover, is particularly an astronomical one.

The specification of any quantity involves two factors. If we speak of three pounds, two metres, or 24 hours, in each case the complete statement consists of firstly a pure numeric, and secondly of a unit of measurement which is either the fundamental unit of reference, or a definite multiple or submultiple of it. The reference units in themselves are entirely arbitrary. There is no "absolute" standard; all measurement is relative.

Problems Involved.—The problem of metrology is twofold. First to provide and maintain unaltered the standards of reference by which other quantities are compared and measured; and Secondly to provide means by which the comparisons may be made with accuracy sufficient for the particular purpose in view. The demands of science and industry at the present day require, for certain purposes, an extremely high degree of accuracy in these fundamental comparisons, so that what, at first sight, would appear to be a fairly simple problem becomes in fact one of great difficulty, involving the most expensive and elaborate apparatus. No measurement is ever absolutely correct. Some degree of experimental error is always necessarily present, and the approximate degrees of accuracy at present attainable in certain of the more fundamental operations in metrology, are as follows:—

Comparison of two platinum-iridium copies of the International Prototype Kilogramme: 1 part in 100,000,000.
Comparison of ordinary chemical weights: 1 part in 1,000,000.
Comparison of smaller masses by micro-balance: 1 part in 100,000,000.
Comparison of two yard or metre (line or end) standards: 1 part in 10,000,000.
Comparison of end standard with line standard: 1 part in 1,000,000.
Determination of volume and density for very special work: 1 part in 1,000,000.
Determination of volume and density, ordinary: 1 part in 10,000.
Calibration of set of end standards (not less than 1 in. in length): 1 part in 1,000,000.
Calibration of subdivisions of graduated yard or metal scale in terms of whole length: 0·000005 in. or 0·0001 millimetre.

STANDARDS OF LENGTH

The history of standards of length is one of varying ascendency of three principal competing types. A length may be defined by the distance, under certain specified conditions, either between the two end surfaces of a material standard bar, or between two suitable marks engraved upon it. Alternatively reference may be made to some "natural" standard. The standard yards of Henry VII. and Elizabeth preserved in the Standards Department of the Board of Trade, are end standards, incisions marking subdivisions of the yard being secondary only. The

Elizabethan yard was superseded by one defined by the distance between two small dots on gold plugs inserted in it. When this bar was legalised in 1824, it was provided that in the event of loss it should be replaced by reference to a "natural" standard, the length of the pendulum beating seconds in the latitude of London. It so happened that within a very short period this standard was in fact destroyed by the fire in the Houses of Parliament in 1834.

The commission charged with its replacement found, however, that it was impossible to reproduce the seconds pendulum with so high an accuracy as the length of the bar itself could be reproduced by means of direct comparison with other bars which had previously been compared with the lost standard. The legal prescription was therefore abandoned, and the new standard yard, which is that legal at the present day, is a line standard constructed by comparison with other bars, without reference to any control provided by a natural standard. The metre was originally intended to be the 10,000,000th part of the earth's meridional quadrant. But it was soon found that not only was the determination of this natural standard an extremely laborious undertaking, but the accuracy attainable was less than that possible in the comparison of material standards, and the material Mètre des Archives, a platinum end standard, became the accepted standard of reference for the metric system until superseded in 1889 by the present International Prototype Metre, a platinum iridium line standard (*see* WEIGHTS AND MEASURES).

Wave Lengths as Natural Standard.—At the date of construction of the present Imperial Standard Yard, and the International Prototype Metre, sound judgment was exercised in the choice of material line standards as affording the greatest prospect of accurate comparison and reproduction and in the legal provision made for their replacement, if necessary, by reference to other similar standards periodically compared with them. Recent developments, however, have appreciably changed the situation. In the first place the experiments of Michelson, followed by those of Fabry and Perot (*see* INTERFERENCE OF LIGHT, 14.685) have finally established a natural standard (the wave length of the red line in the spectrum of cadmium) which is reproducible with accuracy at least as great as that attainable in the comparisons of material standards, which is definitely free from the suspicion of possible secular variation inevitably attaching to all material standards, and by means of which the material standards necessarily employed in everyday practice can be verified in any part of the world without the risk of accident or damage involved in the periodical transport of material national reference standards to and from the international century laboratory for purposes of comparison with the prototype. Secondly, such improvement has been effected during the last few years in the production of flat-ended standards that bars with accurately parallel ends of the quality of optical mirrors are now available, whose lengths can be more directly determined by the method of optical interference than is the case with line standards, and which are also more accurately comparable with each other than the latter.

The International Committee on Weights and Measures, at its meeting in 1923, decided in principle on the eventual adoption of a wave-length standard of length subject to the determination by experiment in the various national laboratories, of the best method of realising such a standard and the conditions necessary to ensure the greatest degree of constancy in its reproduction. Such experiments are proceeding and it is to be anticipated that within the period beginning in 1925 or 1926 a very important change may be made in the ultimate basis of reference for all measures of length.

Use of Material Standards.—Whatever ultimate basis of control may be selected, for practical purposes, in everyday measurement, material standards will always be needed. Both line standards and end standards will always be required for different purposes. So long as material standards are used for the ultimate reference the primary importance attaches to secular stability of the material. There is evidence to suggest that the present imperial standard yard has probably shortened by about
0·0002 inch since it was originally constructed in 1844; but h
remained unchanged for the last 40 years. So far as is known, t
international prototype metre has remained unchanged since i
verification (1875–9). The evidence for this rests partly
subsequent recomparison with various national copies construct
in the same manner at the same time, and partly on two dete
minations, by different methods, at an interval of about
years, the first by Michelson and Benoit, and the second
Fabry and Perot, against the wave length of the red line of ca
mium. These metre standards are all made of an alloy of 90
platinum and 10% iridium, which is now regarded as the mo
satisfactory alloy for the construction of a material standard f
purposes of ultimate reference. Its cost, however, would
prohibitive for any other purpose.

Temperature Conditions.—All materials change in size to
greater or less degree with variation of temperature. It is ther
fore essential to specify exactly the temperature at which t
material standard defines the unit of length, and further eith
to control the standard exactly to this temperature when maki
comparisons with it, or at least to ascertain its temperatu
exactly, and make allowance for its known expansion betwe
that temperature and the standard temperature. The Imper
Standard Yard is correct at 62° F., the International Prototy
Metre at 0° Centigrade. Some confusion of thought frequent
arises on this point. Each of these bars serves, at its own stan
ard temperature, to define a simple unit of pure length, that is,
absolute extension in space. These units themselves, once det
mined, are entirely independent of temperature. It is not corr
to say that either of the fundamental reference standards is
yard, or a metre, except at its appropriate temperature of defi
tion, 62° F. or 0° C., respectively, nor that a length of any oth
material is a yard or a metre solely because at 62° F. or at 0°
it agrees with the fundamental standard. A length of any ma
rial is a yard or a metre, at whatever temperature it may be, if
that particular temperature the length is equal to the unit
fined by the standard bar when the latter is at its own tempe
ture of reference. There is a definite numerical relationship
tween the two principal units which has been twice accurately
termined: in 1895 by Chaney and Benoit, with the result 1 metre
39.370113 in.; and more recently (1922–5) at the National Ph
sical Laboratory, with the result 1 metre = 39·370137 inch
The two results may be said to be in agreement within the
perimental error of the various observations involved, and
all practical purposes the simple ratio 1 in. = 25·4 mm. (equi
lent to 1 metre = 39·370079 in.) may be taken as sufficient
exact.

The use of this ratio implies that the two objects, being co
pared, are both simultaneously at their common temperature
employment. For all everyday purposes of measurement, as
example in measuring a piece of work in an engineering wo
shop, it is unnecessary to bring the object to be measured to t
standard temperature. If the work and the gauge with whi
it is being measured are made of materials having the same
efficient of expansion, and the former has been compared wi
the reference standard at the standard temperature, it is o
necessary, when comparing the work with the gauge, to ensu
that both are at the same temperature (not necessarily the stan
ard temperature) to ensure that the work will be correct
measured.

Use of Invar.—For many purposes where very precise mea
urement is involved, it is of great advantage to have a mater
with a very small thermal expansion. Two such materials ha
been discovered. The first, known as "Invar," is a nickel-ste
alloy, containing 36% of nickel, invented by Dr. Ch. Ed. Guillau
of the Bureau International (Sèvres). Different samples ha
coefficients ranging from about 1.5×10^{-6} per 1° C., for lar
bars, down to zero, or even slightly negative values, for small
bars, pendulum rods, drawn wire or rolled tape. These figur
are to be compared with 11×10^{-6} per 1° C. for steel, and 18 × 1
per 1° C. for brass. Invar, unfortunately, has one very serio
defect as a standard of length. It grows longer, rapidly at fi
and subsequently more slowly but continuously, so that aft

o years the length of a bar of invar will still be increasing at a ıte of about 1 part in 2,000,000 per annum. More recently r. Guillaume has introduced a slightly different alloy, contain- ıg a percentage of chromium in addition to the nickel, which is escribed as "stable" invar. This alloy grows at an appre- ably slower rate than ordinary invar, but still cannot be regarded constant. Invar therefore is principally useful in a laboratory, work where temporary constancy of length is the primary nsideration, or in circumstances, as for example in the case of pes and wires used for geodetic surveying, where the accurate certainment of temperature presents considerable difficulty. these cases it is necessary to return the tapes or wires to the boratory periodically for reverification. For the reasons indi- ted above, in everyday workshop measurements, gauges or ales should be made of material having a similar coefficient expansion to the work to be measured, and invar therefore ould not ordinarily be used for the construction of workshop ndards.

Fused Silica.—The other material which has a very low co- icient of expansion is fused silica, which expands only $0{\cdot}4\times10^{-6}$ r 1° Centigrade. A metre standard constructed of fused silica, in form of a tube, with parallel plates fused in at the ends on the tinised surfaces of which the defining lines are ruled, has been de and kept under observation at the National Physical boratory since 1913. So far as can be detected, no change occurred in its length.. Such a standard is extremely fragile, for this reason would hardly be adopted either as a funda- ntal reference standard or for everyday use, except in a metro- ical laboratory.

Vatural Crystal Quartz.—Reference should be made to the ent work of Perard, at the Bureau International, on end ndards of natural crystal quartz. Such standards cannot, course, be of the full length of the yard or metre. But they sent several great advantages. Firstly, since the material is of at age and the molecules of which it is composed are arranged ıcturally in definite crystallised array, there seems little pos- lity of any secular change. Secondly, it lends itself to perfect ical finish of the defining end planes, which enables direct ermination of length to be made in terms of light waves, with remely high precision resulting in a proportional accuracy no than is at present obtained in the comparison of yard or re line standards, although the largest available specimens rystal quartz, as well as the method of use, only enable such ndards to be made and verified up to a length of about 4 es.

ine Standards; Mode of Comparison.—The comparison of two line dards is effected as follows: The bars are placed side by side, on one of two parallel girders contained in a water bath, which ounted on a carriage capable of being moved in a direction endicular to the length of the bars. The bars are constructed their graduations on polished surfaces in the neutral plane eir cross section, and each is supported on two rollers spaced ıch a distance apart that the distance between its graduation ks has a maximum value. Under these conditions any changes e flexure of the bars due to slight errors in the positions of the orts can have no effect on the measured distances between graduations. Two micrometer microscopes (*see* MICROMETER, 81) are rigidly held in brackets supported in such a manner be unaffected by the motion of the carriage. Each girder independent adjustments by means of which the lines on the can be brought into focus in the field of the microscopes. The r in the bath is stirred and the temperature read by means ccurately calibrated thermometers. Readings are taken by ıs of the microscopes alternately on the defining lines of each and the mean of several independent readings is taken. The arison is repeated with each of the bars turned end for end in in order to overcome any effect of asymmetry in the illumina- of the graduation marks, and the bars are then interchanged on wo girders and the whole repeated once more, making eight lete sets of readings in all, from which the difference in length een the two bars is finally computed. In an important deter- tion several bars (say six or eight) may be included, and each e completely compared in the manner described above, against e others, the best values for the differences between all the us bars being then computed from the individual observed ences by the method of least squares (*see* PROBABILITY, 22.376), esidual errors serving to indicate the degree of accuracy which een attained in the work.

Calibration.—The calibration of the subdivisions of a divided scale is done in a similar way, except that in this case the carriage of the comparator moves in the direction of the length of the bar. The microscopes are fixed successively at a series of suitable intervals apart, for example, 1 dm., 2 dm., 3 dm., etc., and each principal interval of 1 dm., 2 dm., etc., is compared with every other interval of the same magnitude throughout the metre. By computation from the results so obtained the value of each decimetre is determined in relation to the whole length of the scale. In a similar manner each centimetre of one decimetre is compared with every centimetre of another decimetre, and as a result the value of each centimetre is found in relation to the whole of the other decimetre, and so in turn, in relation to the whole length of the metre. Millimetres are derived from centimetres in the same way, and so on. The complete calibration of a divided scale will be seen to be a very laborious process involving an enormous number of observations. The process is, however, simplified by the fact that the whole of the measurements are made on the one bar, so that, provided reasonable precautions are taken to ensure constancy of temperature, exact temperature measurements are not important.

The apparatus used to determine coefficients of expansion is similar to the transverse comparator, but has two independent water baths mounted on the carriage. One of these, containing a bar preferably of invar, is kept at a constant temperature, while the other, containing the bar under examination, is brought successively to a series of suitable temperatures. The two bars are compared under the microscopes at each temperature of the second, and so the variations of its length with temperature are determined.

A number of machines of different types, and varying sensitivity, are available for comparing end standards by contact measurement, or, if the end faces are of sufficiently perfect finish, they may be directly compared by the method of optical interference. In the latter case the two bars are brought in turn between two semi-silvered optically flat glass surfaces, and the number of wave lengths in the small spaces at either end between the measuring surface of the bar, and the semi-silvered surfaces of the optical flats are determined by direct measurement of the angular diameters of the interference rings formed by monochromatic light. This enables the fraction of a wave length to be determined with exactness, and if several different wave lengths are used in turn, whose mutual ratios are known, the whole number of waves is easily determined by deduction, as only a particular set of corresponding whole numbers will give fractions agreeing in every case with the series actually observed.

In the mechanical contact type of measuring machine the bar is measured between two opposed anvils, one of which may either be fixed, or may be movable by means of a micrometer screw, while the other is capable of a small movement operating some form of sensitive indicator. The two bars to be compared are inserted in turn between the anvils, and if the whole difference between them is sufficiently small the movement of the indicator over a calibrated scale may suffice to determine it. If the difference is greater, the indicator must be brought to a fixed mark by an adjustment of the moving anvil, the difference in length being then ascertained by the difference in reading of the micrometer wheel.

Mode of Calibration of End Standards.—The calibration of a set of subdivisional end standards is effected by taking them together in pairs of nominally equal added lengths, and comparing their sums, in the manner just described. In the last 20 years there have been developed, first by the firm of C. E. Johansson, Sweden, and later at the National Physical Laboratory, England, and by Hoke in America, methods of producing short flat ended gauges of such perfection that any two of them if put together will adhere firmly to each other by "wringing." The process of wringing is not yet fully understood, but appears to depend essentially on the presence of a very minute trace of liquid (grease or moisture) between the surfaces of the gauges. These gauges are usually made in series, *e.g.*, 1 in., 0·9 in., 0·8 in. . . . 0·1 inch. Suppose we wish to calibrate such a series, of which the 1 in. is supposed to be already known as the result of some previous calibration. For convenience we will assume that we have available a duplicate set of pieces, which we denote by 0·1′, 0·2′, 0·9 foot. To determine, for example, the value of the 0·7-in. gauge, we wring up in turn all the various nominally equal combinations indicated below, and compare them in a suitable measuring machine, the small observed differences being indicated by

0·7		=		0·7	0	0·7	0·5	=	1·0	0·2	5
0·7	0·1	=		0·8	1	0·7	0·6	=	1·0	0·3	6
0·7	0·2	=		0·9	2	0·7	0·7	=	1·0	0·4	7
0·7	0·3	=	1·0		3	0·7	0·8	=	1·0	0·5	8
0·7	0·4	=	1·0	0·1	4	0·7	0·9	=	1·0	0·6	9

Adding up all these equations we see that the sums of the second columns on either side cancel out, and we get

$$10\times0{\cdot}7 = 7\times1{\cdot}0 \quad {}^{9}_{0}$$

or

$$0{\cdot}7 = \frac{7}{10}\times1{\cdot}0 \quad \frac{1}{10} \; {}^{9}_{0}$$

The sizes of each of the other pieces may be determined in a precisely similar manner.

It may be noted that in the determination of sizes in this manner, the length of each gauge is automatically associated with the thickness of one wringing film, which, for clearness in conception, may be regarded as representing half a film thickness on either end surface, so that when two gauges are wrung together a whole film is established between them. As the gauges are normally used in this manner, this result is logically what is required. The wringing films, moreover, are in any case exceedingly thin. When initially formed, their thickness depends to some extent on the viscosity of the liquid of which they are composed, but if a sufficient length of time is allowed to elapse they tend to thin down to a limiting thickness which is less than 0·000001 in. for all liquids.

There is one more fundamental operation which, whatever may be the nature of the ultimate standard adopted, will always be required in its practical application to everyday requirements, and that is the determination of the length of an end standard in terms of the corresponding line standard, or vice versa. This is a matter of considerable difficulty, and several methods have been employed for the purpose. Probably the best method is that introduced by Mr. H. L. P. Jolly, formerly of the National Physical Laboratory, and now of the Ordnance Survey Department, Southampton. It involves the use of an intermediate end standard, and of two special parallel faced end blocks, which can be wrung on to the ends of this standard.

Each of the end blocks carries graduation marks as shown on its polished upper surface. The composite bar is compared in the ordinary way in a comparator, with the standard line bar. Each of the end blocks is turned round in turn, and re-wrung on the end of the bar, and the comparison repeated. We thus obtain the four results:—

$$\begin{aligned} L \quad a_2 \quad b_1 &= S_L \quad 1 \\ L \quad a_1 \quad b_1 &= S_L \quad 2 \\ L \quad a_1 \quad b_2 &= S_L \quad 3 \\ L \quad a_2 \quad b_2 &= S_L \quad 4 \end{aligned}$$

or, adding and dividing by 2

$$2L \quad a_1 \quad a_2 \quad b_1 \quad b_2 = 2S_L \quad \tfrac{1}{2} \quad 1 \quad 2 \quad 3 \quad 4$$

Each of the end blocks is then removed in turn and the other wrung centrally on the end of the bar, the new combinations being compared in a measuring machine with the end standard end bar, with the results

$$\begin{aligned} L \quad a_1 \quad a_2 &= S_E \quad 1 \\ L \quad b_1 \quad b_2 &= S_E \quad 2 \end{aligned}$$

or adding

$$2\,L \quad a_1 \quad a_2 \quad b_1 \quad b_2 = 2\,S_E \quad 1 \quad 2$$

From this equation, and the one previously found, we obtain the result

$$2\,S_L \quad \tfrac{1}{2} \quad (1 \quad 2 \quad 3 \quad 4) = 2\,S_E \quad 1 \quad 2$$

which gives us the desired value of the line standard S_L in terms of the end standard S_E or vice versa.

To complete our survey of the fundamental operations involved in length measurement, reference must be made finally and very briefly to the process of verifying longer measures, such as are used in surveying. In the first place a long bar, graduated in multiples of the standard length unit, is required. This is compared, yard by yard, or metre by metre, with the standard line bar, in a large comparator. This bar in turn is compared either with suitable reference marks engraved on metal studs let into a mural base at intervals corresponding to the length of the bar, or else directly with the divisions of a graduated tape. The tapes or wires after verification, either directly, or by comparison with the mural base, are used to determine base lines in the field, by comparison with temporary bench marks set up at intervals apart roughly equal to the length of the tape.

Standards of Mass.—No attempt has so far been made to define a unit of mass by means of any natural standard, though a standard of this kind, *e.g.*, a definite multiple, say, of the atomic mass of helium, would not be inconceivable. Prior to the discovery of the radioactive elements mass was regarded as the essentially constant attribute of matter, and there was no reason to anticipate any change in a material standard of mass except by actual damage due to abrasion, oxidation, hygroscopic absorption or other similar causes. And there still remains a reasonable choice of materials, which, given due care in preservation and handling, may be expected with considerable confidence to exhibit constancy of mass.

Platinum and Platinum-Iridium.—Our predecessors, ignorant of radioactive processes, were fortunate in the choice of platinum and platinum-iridium (10% iridium) as the materials of construction for the ultimate reference standards of mass, the Imperial Standard Pound, and the International Prototype Kilogramme, respectively. The degree of consistency (within 1 part in 10^8) with which recomparisons of various national copies of the kilogramme, made after the lapse of many years, have i general repeated the original determinations, speaks convincingly, not only as to the suitability of the standards themselves but as to the perfection of the balances used in the comparisons The relation between the two units, according to the best ascertained determination, is 1 kg. = 2·2046223 pounds. This valu received legal sanction.

Crystal Quartz.—Another material presenting a high degree c constancy of mass is crystal quartz. This, however, has the disadvantage of having a comparatively low density. In comparin two standard weights, masses in air, allowance must be made fo the upward buoyant effect due to the volumes of air whic they respectively displace. The less the density of the mass, th greater will be the buoyancy correction. The accuracy attaine in the intercomparison of a series of platinum-iridium standard is no doubt attributable to a considerable degree to the fact tha they all have comparatively high, and very closely equal, densities, so that the net buoyancy corrections are very smal and a comparatively rough determination of the air density consequently suffices to give the correction with negligible erro In comparing a number of masses differing appreciably in density, *e.g.*, platinum, quartz and brass, the accurate determinatio of the buoyancy correction presents much greater difficulty, an several attempts have been made to overcome it by actuall conducting the weighings *in vacuo*. This involves enclosing th whole balance in an air-tight case, and manipulating the weight entirely by mechanical means from outside, without opening th case. Leakage at the glands where the operating spindles ente the case has, however, so far proved an almost insuperable obstacle to successful weighing *in vacuo*. Everyday weighings fo commercial purposes are of course necessarily conducted in ai but the differences in buoyancy between the weights used, an the goods weighed, are negligible for this purpose. It is nece sary, however, to provide a basis for the periodical reverificatio by inspectors of weights and measures of traders' weights, whic may be of iron, brass or other materials. For this purpose "commercial" standard is employed. This standard is of bra (of density 8·143) adjusted to agree *in vacuo* with the Imperi Standard Pound of platinum. Inspectors' standards are al of brass, and all verifications of these standards, and thus ind rectly of traders' weights, are made by comparison, *in air*, wi the commercial brass pound.

Use of the Balance.—Even when weighings are not conducte *in vacuo* the construction and manipulation of a balance for t accurate comparison of primary standards of mass are distinct elaborate. It is necessary for the greatest care to be taken preserve constancy of temperature, in order to maintain a stea zero reading of the balance. For this reason the room containi the balance must be thermostatically controlled, and the observ either works entirely from outside the room, or, if he ente it, must remain at a distance from the balance, all the manip lation of the weights being effected from outside the balance ca by mechanical control operated by means of long rods, and t movement of the balance beam being observed either through telescope, or by the movement across a scale of a spot of lig reflected by a small mirror attached to the beam.

Consecutive Weighings.—To eliminate any effect due to slig inequality in the lengths of the two arms of the balance, the same time to minimise the effect of any small residual dr of zero due to a gradual change in temperature conditions a to obtain a determination of the sensitivity of the balance at t time of weighing, consecutive weighings should be made to t following order:—

Left-hand pan	Right-hand pan	Mean Reading
A x	B	p_1
A	B x	p_2
B	A x	p_3
B x	A	p_4
B x	A	p_5
B	A x	p_6
A	B x	p_7
A x	B	p_8

Here A and B are the two masses being compared, and x a small known weight which serves to determine the sensitivity. Each mass is weighed an equal number of times on each pan of the balance, and the mean time of all the weighings of each mass on each pan is the same, so that the effect of any steady temperature drift is eliminated. In weighing, the balance is not brought to rest, but the pointer, or spot of light, is observed while swinging, and the extreme positions of several successive swings to right and left are noted. From these the mean readings or rest points corresponding to each arrangement of weights on the scale pans are calculated. If, for example, four successive readings are 1 2 3 4, then, allowing for the effect of the gradual reduction in the amplitude of the swing, due to damping, the corresponding rest point, p, is $\frac{1}{8}$ (1 3 2 3 3 4).

If p be the rest point when two *equal* masses of values nominally equal to A and B are on the pans, then we have

$$\begin{aligned} A-B\quad x&=k(p_1-p) & B-A\quad x&=k(p_5-p)\\ A-B-x&=k(p_2-p) & B-A-x&=k(p_6-p)\\ B-A-x&=k(p_3-p) & A-B-x&=k(p_7-p)\\ B-A\quad x&=k(p_4-p) & A-B\quad x&=k(p_8-p) \end{aligned}$$

whence

$$\begin{aligned} 8\ (A-B)&=k(p_1\quad p_2-p_3-p_4-p_5-p_6\quad p_7\quad p_8)\\ 8\ \cdot x&=k(p_1-p_2-p_3\quad p_4\quad p_5-p_6-p_7\quad p_8)\\ \text{or } A-B&=x\,\frac{p_1\quad p_2-p_3-p_4-p_5-p_6-p_7\quad p_8}{p_1-p_2-p_3\quad p_4\quad p_5-p_6-p_7\quad p_8} \end{aligned}$$

Usually of course several masses will be compared each with each n turn, and the best values for the differences between them finally omputed by the method of least squares from all the observed ifferences obtained in the above manner.

The construction of the balance must be such as to ensure that fter each successive arrestment of the beam and pans, the knife dges are brought into exactly the same relationship with the planes, nd to secure this it is necessary to support the pans by means of a eries of crossed knife edges below each terminal knife edge on the eam. If the weighings are not conducted *in vacuo*, the air density ust be calculated for each weighing from observations of temperaure, pressure and hygroscopic state of the air, and each observed ading corrected for air buoyancy, allowing for the effect of temerature on the volumes of the weights.

The volumes, and hence the densities, of the weights are determined by weighing them, first in air, and then immersed in distilled ater, against other weights always in air. The density of the air ust be calculated as usual from its temperature, barometric essure and humidity, and that of the distilled water is known om its temperature. The difference between the two weighings, he allowance being made for the air buoyancy corrections on all e weights involved, is equal to the difference in weight between e quantities of water and air at the observed densities of each, ich would fill a volume equal to that of the weight being examined. for any reason it is considered objectionable to immerse a standard eight in water, it is possible to determine its volume, though somehat less accurately, by means of a volumenometer, which is an paratus for observing the change of pressure of the air enclosed thin a given space, when a definite change is made in its volume, stly when it is filled with air alone, and secondly when the weight enclosed within it.

The calibration of a set of fractional or multiple weights in terms the original unit can be effected by weighing together in groups of minally equal sum by a process precisely analogous to that deibed above for a set of fractional end standards.

Ordinary brass weights usually exhibit a certain variability of ss, which is probably attributable to variations of surface condin depending on the degree of humidity of the surrounding atmosere. Care should, of course, be taken to see that the metal of ich weights are made is free from porosity, and weights intended precision work should be made solid, without screwed-in tops ering holes containing adjusting material. The surfaces of high ss weights are frequently electro plated with gold or platinum, h the object of minimising the effects of oxidation and hygroscopic ion on the surface. Of the two, platinising is the preferable ocess, but weights coated with either gold or platinum have been nd to exhibit instability to a certain degree, though usually less n in the case of unplated weights. The success of gilding or tinising depends upon the care exercised to obtain a firm and hard osit.

o minimise the effects of temperature upon the action of a ance, a beam of invar may be used. But it must be remembered t invar is to a certain extent magnetic, and if results of high preon are required, care must be taken with such a beam as to ensure t it is completely screened from any possible magnetic influence. e balance should preferably be entirely enclosed within a sheet case.

or weighing very small quantities, and in particular for coming the densities of small quantities of gases, micro-balances concted entirely of fused quartz have been used. Such balances e been made both with knife edges, and preferably, with the m torsionally supported on a thin horizontal quartz fibre at t angles to its length, and the pans supported from its ends by ns of other fibres fused directly to it. The weighings are usually made by arranging a small bulb or similar contrivance at one end of the beam, counter-balanced by solid quartz at the other end. The two ends of the beam are therefore differently affected by the buoyancy of the air, and weighings are made by adjusting the pressure of the air in the balance case until the buoyancy just restores the beam to balance. The air pressure is read by means of a suitable manometer, and serves to measure the weight of the object under examination. With such balances loads as small as $\frac{1}{10}$th gramme have been weighed to an accuracy of 1 part in 10^8).

STANDARDS OF CAPACITY

Theoretically, the unit of capacity should be the same as the unit of volume—that is, the volume of a cube each of whose sides is equal to the unit of length. In practice, however, it is extremely difficult to construct such a cube with accuracy, and still more difficult to measure the internal volumes of vessels of different shapes in terms of the unit of length. Practical necessity has therefore ordained the use of a unit of capacity based on the unit of mass, rather than on the unit of length. In the metric system the kilogramme was originally intended to be the mass of one cubic decimetre of pure distilled water when at its temperature of maximum density (4° Centigrade).

Although great care was taken in the construction of the original kilogramme from this definition, and the result attained was closer than might have been anticipated in view of the difficulty of the problem, it has been found by very careful experiment that the litre, which is now defined as the volume occupied by 1 kilogramme of water at 4° C., actually equals 1·000027 cubic decimetres. The gallon is somewhat similarly defined as the volume occupied by 10 lb. of pure distilled water at 62° F. when weighed in air at a barometric pressure of 30 in. of mercury, against brass weights. As the weighing has to be made in air, and the density of the brass weights is not prescribed by the Act (Weights and Measures Act 1878) there is a certain ambiguity about this definition. On reasonable assumptions it has been calculated that 1 gallon = 4·5459631 litres.

It will be noted that in the case of the litre the definition refers to the kilogramme *mass*—that is to say, the weighings are to be reduced to vacuum, by applying a suitable correction for the difference of the air buoyancy on the distilled water and on the weights used for weighing it. This entirely eliminates the difficulty mentioned as regards the exact definition of the gallon. Much confusion of thought has, however, arisen from the preference of some chemists for the use of the so-called "Mohr's litre," which is defined, on the same lines as the gallon, as the volume occupied by 1 kg. of distilled water, when weighed in air, against brass weights, at a temperature which has never been explicitly laid down. Roughly, a Mohr's litre equals 1·002 true litres. It is very unfortunate that the term litre should have been appropriated to a unit so vaguely defined and which differs from the true litre by an amount that, although small, is too great to be negligible. For most purposes the difference between the millilitre and the cubic centimetre can safely be neglected.

Commercial Purposes.—For commercial purposes the gallon and the litre are both represented by material standards of capacity, constructed as nearly as possible in accordance with their respective definitions. These standards are in the form of cylindrical metal vessels with flat brims, and are filled exactly to their brims by the aid of flat glass "strikes." Comparisons with other vessels are made by transfer, the vessel under comparison being first filled and emptied to compensate for the amount of water left behind in the standard when the latter is emptied into the vessel being tested.

Scientific Purposes.—For scientific apparatus, such as flasks, burettes, pipettes, etc., where higher accuracy is needed, it is found necessary as a rule to base the verification directly on the original definition by actually weighing the quantity of pure distilled water contained in, or delivered from, the vessel, making due allowance for the temperature of the water at the time of weighing and for the buoyancy of the surrounding air. In the case of vessels, such as burettes and pipettes, which are intended to deliver, and not to contain, definite quantities of liquid, it must be remembered that after delivery the walls are left wet to an extent which depends not only on the rate at which delivery is effected and the time allowed for subsequent drainage but also on the viscosity and surface tension of the liquid being measured. The rate of delivery is of more importance than the drainage time, and provided it is sufficiently slow the quantity of liquid delivered will be reasonably constant. Suitable delivery times and error allowances are scheduled in a pamphlet on testing volumetric glassware issued by the National Physical Laboratory.

BIBLIOGRAPHY.—The literature of metrology is somewhat scattered. The best collected account will be found in a series of articles contained in the *Dictionary of Applied Physics* (1922–3) (and in particular vol. 3 thereof), edited by Sir R. T. Glazebrook, K.C.B., F.R.S., and published by Macmillan, London. Many detailed references are given in these articles. For full descriptions of the more fundamental operations the various volumes of the *Travaux et Mémoires du Bureau International des Poids et Mesures* (Paris, Gautier-Villars) should be consulted. In addition, consult the annual reports of the Standards Department, Board of Trade (H.M. Stationery Office, London); Miller, *Phil. Trans.*, 146 (1856), on the construction of the new standard pound; Airy, *Phil. Trans.*, pt. 3, p. 17 (1857), on the construction of the new standard yard; Kaye, "A Silica Standard of Length," *Proc. Roy. Soc.*, A85 (1911); Michelson, *Light Waves and Their Uses* (Chicago University Press); C. E. Soc.*, 32, 374; Sears, *Precise Length Measurements*, Cantor Lectures, Royal Society of Arts (1923).

(J. E. SE.)

MEASURING INSTRUMENTS.—The World War was responsible for a considerable development and improvement of apparatus intended for the measurement of engineers' gauges and products. (*See* MEASUREMENTS.)

Whitworth Gauges.—Improvement in accuracy of measurement necessarily goes hand in hand with improvement in accuracy and perfection of manufacture of the articles to be measured. The original measuring machine of Sir Joseph Whitworth would have been of little value apart from the system of accurate standards (both end gauges and cylindrical gauges) which he produced for use with it. If an object is not regularly formed to a certain degree of accuracy, it cannot be said to possess a definite measurement to that degree of accuracy, and it is useless to employ measuring apparatus capable of yielding results of still higher accuracy. On the other hand, while there is no great difficulty in designing highly sensitive indicating devices, it is practically impossible to calibrate them in the absence of standards measurable to the degree of accuracy aimed at.

Johansson's Gauges.—The first substantial advance in accuracy subsequent to Whitworth's work was the introduction by the Swedish firm of Johansson, in 1908, of flat parallel faced slip and block gauges of such perfection of workmanship that any two of them, when cleaned, would "wring" together. The gauges were made in series differing by definite small amounts, so chosen that by wringing together a suitable combination of pieces, any desired size, to the nearest 0·0001 in., could be produced. To ensure this accuracy, it is necessary that the individual pieces should each have a guaranteed accuracy of (say) 0·00001 in., in order that the cumulated error of a group of four or five should not exceed 0·00005 inch. And in order to assert with confidence that this degree of accuracy is, or is not, in fact attained in an individual piece it is necessary to be able to measure with an accuracy of the order of 0·000001 inch. When the Johansson gauges were first introduced no appliances were available which could be relied on to give measurements of this accuracy. Three entirely different methods have since been developed, however, which enable it to be done, and which, with due precautions, give mutually consistent results. These are:—

Tilting Level Comparator.—(*a*) the "tilting level" comparator, due to A. J. C. Brookes, in which the two gauges, or groups of gauges, to be compared are stood side by side on a level surface plate, and the difference in their heights is determined by the reading of a highly sensitive level, which rests by point contact upon their upper surfaces, through two ball feet.

Millionth Comparator.—(*b*) the "millionth" comparator, due to J. E. Sears, jun., wherein measurements are made between two flat parallel anvils, giving a local surface contact, the one anvil being fixed, and the other connected, through a series of spring suspensions designed to eliminate all frictional effects, with a sensitive tilting mirror which causes a spot of light to move across a scale, giving a magnified image of the displacement of the anvil on a scale of abou 30,000 to 1.

Optical Interference.—(*c*) the method of optical interferenc developed at the Bureau of Standards, Washington, wherein th whole surfaces of the gauges under comparison may be inspecte being marked out into contours of approximately 0·00001 in. difference in height by the alternate light and dark bands forming th interference pattern.

MEASUREMENT OF INTERNAL DIMENSIONS

Another matter of fundamental importance which has bu lately found a satisfactory solution is the measurement of inte nal dimensions. The transference from external to interna measurement constituted a considerable difficulty; and the size of such objects as ring gauges, either plain or screwed, wer usually estimated by the nature of their fit upon correspondin plug gauges. As the fit depends to a very marked extent upo the amount and nature of the lubricant used, considerable un certainty existed as to the correct interpretation of the observe results. If well finished and liberally lubricated with thic grease, a cylindrical plug gauge will enter and pass through ring gauge definitely smaller than itself without damage to eithe Two instruments have now been produced for the measuremen of internal diameters of either plain or screwed rings, which giv results mutually consistent, if due care is taken, and the wor being measured is sufficiently uniform in its dimensions, to th order of 0·00001 inch.

Chord Contact Type.—In the "chord contact" machine, du to G. A. Tomlinson, the diameter of the ring is deduced b calculation from the measured displacement, in a direction pe pendicular to its length, of a double ball-ended distance piece known length, which is allowed to make contact inside the rin first on one side, and then on the other side, of the diameter.

Displacement Machine.—In the "displacement" type of in ternal measuring machine, due to J. E. Sears, the position of th ring is so adjusted that measurements are made exactly acros the diameter. The ring is mounted on a carriage, which can b moved bodily in the direction of the diameter being measure by means of suitable micrometers. Contact is made first o one side of the ring, and then on the other, with a double-ende stylus attached to a sensitive indicating mechanism, and th micrometer readings are taken when the indicator reads zer The same is done in turn with a standard plug substituted f the ring, provision being made for withdrawing the stylus tem porarily as the plug passes across. If x_1 y_1 x_2 y_2 are the four m crometer readings, the displacements d_1 and d_2 are equal to x_2- and y_1-y_2 respectively, and it is to be noticed that the pressu on the stylus is in the same direction when both x readings a taken, and also when both y readings are taken, so that an possible errors due to backlash or flexure in the indicating mec anism are eliminated. The transition from external to inte nal measurement is thus directly accomplished, and the fin result is given by the equation

$$R - d_1 + d_2 - P = (x_2 - x_1) + (y_1 - y_2) - P$$

SCIENTIFIC PRINCIPLES

The question of the general geometrical principles underlyi the correct design of instruments intended to give the highe accuracy of measurement has received greater attention in rece years. Questions of the proper application of the theory kinematic constraint to ensure definite and repeatable regi ter of parts, of eliminating backlash and friction effects, of pr venting components of errors due to inevitable imperfectio of workmanship (*e.g.*, in sliding ways) from becoming effe tive in the actual direction of measurement, of the design an relationing of parts so that elastic deformations due to chan ing distributions of load do not affect the results, and so o are all involved here.

Travelling Microscope Comparator.—These various poin have been fully considered in the "travelling microscope com parator" designed by J. E. Sears, jun., for the Metrology D partment of the National Physical Laboratory. The long l of an L-shaped carriage, which bears two microscopes, is su ported on two wheels running in a V-guide along the upper side of the machine bed, so that whatever position is taken up by the carriage its form is undisturbed. The focal points of the two microscopes are arranged to lie in the extension of the axis of the micrometer screw, and the object to be measured is supported on an independent carriage which, by means of a small weight attached to a cord passing over a pulley, is held permanently in contact with a stud at the end of the screw abutment. Thus errors of straightness in the V-groove are non-effective, and so is any distortion of the base of the machine proper, due to the movement of the microscope carriage. Advantage is taken of the simple ratio 1 in. = 25·4 mm. (which is correct to within 1½ parts in 1,000,000) to obtain simultaneous readings of equal accuracy in either British or the metric system, by means of suitable gearing in the compound micrometer head. The verniers read to 0·00001 in. and 0·0001 mm. respectively. The instrument can be used either with one microscope for making direct measurements against its own calibrated micrometer screw, or, using the two microscopes as a comparator, for determining the values of the sub-divisions of short scales. It has been found of considerable value in measuring the spacing intervals of diffraction gratings.

Screw Gauges.—In the course of the War the necessity for rapid measurement of large numbers of screw gauges led to the development of special machines for the measurement of both pitch and effective diameter of screw threads. E. M. Eden, then of the National Physical Laboratory, was largely instrumental in this work and in the development of the optical projection method of examining profiles of gauges, both screws and flat templets. For the latter, he found lens combinations capable of giving an undistorted magnification of 50 times over a field of initial diameter approaching two inches. These combinations were incorporated in the now well-known "horizontal projector." For screw gauges the "vertical projector" was designed, in which the path of the light is vertical, and the image-forming rays are reflected back from an optically flat mirror overhead on to a specially prepared thread-form diagram placed on the table of the machine. The screw in this case is mounted in a carriage provided with two horizontal micrometer traverses in directions parallel and perpendicular to its axis, respectively, so that measurements of pitch and diameter can be made at the same time as the accuracy of the thread form is examined.

Wilson Projection Gauge.—Mention should also be made of the Wilson projection gauge, in which the optical system is duplicated, so that the two opposite sides of a screw can be projected simultaneously on to the screen, in such a manner that the two images of the thread intermesh, and if the screw is of direct form and size, and the apparatus correctly adjusted, exactly meet. If the screw is small a space is left between the images of its two sides; if large they overlap.

The projection method has naturally proved of great value in a number of other ways. In particular, it has been used in connection with the measurement of gear wheels and gear cutting hobs. Machines for this purpose have been designed by G. A. Tomlinson, and depend for their use on the accurate reproduction of the profiles of the teeth of the gear or hob, in the form of traces made on smoked glass, by a needle point attached to a specially designed pantograph. One of the machines is also fitted with a device for recording, in a similar manner, the relative velocities of rotation of two gear wheels when in mesh. In both cases the smoked glass, bearing the record, is put into the projection apparatus and magnified 50 times at the screen. It is found that the traces are quite sharp in the magnified image, and measurements can be made corresponding to an accuracy of about 0·0001 or 0·0002 inch on the original.

MEAT: *see* FOOD SUPPLY.

MECCA (*see* 17.950), capital of the Hejaz, had a resident population of about 70,000 in 1916, including some 12,000 Indians. The annual pilgrimage brings normally at least 200,000 visitors to the city, of whom pilgrims from British India and the Malay States may number 25,000. Pilgrims have been fewer during and since the World War, owing to disturbed conditions in the Hejaz. Mecca was taken by the Arabs in 1916, and bombarded by the Turks, who damaged the Great Mosque. The Grand Sherif of Mecca, Hussein ibn Ali, of the Hushimite dynasty, proclaimed the independence of the Hejaz in 1916, and assumed the kingly title. In May 1924 he proclaimed himself Caliph, but shortly afterwards was driven from Mecca and forced to abdicate in Nov. of the same year by Ibn Saud, Sultan of Nejd, who invaded the Hejaz and entered Mecca without opposition. The holy places were not damaged by Ibn Saud and his Wahabis, who performed the customary rites in the Great Mosque.

The general aspect of Mecca, as observed during the War, had changed but little, though some modern buildings had sprung up; there were a number of stately residences, including the new royal palace of six storeys, and a considerable display of wealth. The sanitation and water supply, previously very bad, had been improved. There was telegraphic communication between Mecca and Jidda, and between Mecca and Taif, the summer residence of the king, 75 m. to the southeast. Representatives of foreign powers live at Jidda, since non-Moslems are not allowed to enter Mecca.

MECHNIKOV, ILYA (1845–1916), Russian biologist, was born at Ivanovka, in the province of Kharkov, May 15 1845. At the age of 17 he entered the Kharkov University and two years later went to Germany. In 1867 he returned to Russia and was a *dozent* in zoology both at Odessa and St. Petersburg, becoming in 1870 professor ordinarius of zoology and comparative anatomy at Odessa. In 1882 he went to Messina and there began his studies into the nature and habits of microbes. Henceforth he devoted himself to pathological study and in 1888 went to Pasteur in Paris, who gave him a laboratory in the École Normale. By 1892 his views on the essential importance of phagocytosis were firmly established. In that year he published *The Comparative Pathology of Inflammation*, followed in 1901 by his chief work, *Immunity in Infectious Diseases*, and a more popular treatise, *The Nature of Man* (1903). In later years he made a special study of the bacteria infesting the alimentary canal of man. In 1908 he was awarded the Nobel Prize for medicine. He died in Paris July 16 1916. See *Life* by his wife, Olga Mechnikov (1920), trans. by Mrs. R. L. Devonshire (1921).

MEDALS AND DECORATIONS (*see* 18.2; 15.860).—These may be divided into two classes, personal and service. Personal decorations are awarded to the individual (Victoria Cross, etc.); service decorations are awarded to all persons who participate in a common service (war medals, etc.). As a result of the World War the issue of medals and decorations was the widest ever recorded, and, of these, the best known is the Victory medal.

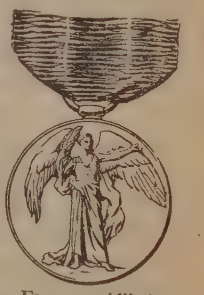

FIG. 1.—Allied Victory Medal.

In 1918 the Allies agreed to issue a collective and distinctive medal to commemorate the War. The advantages of this were that it was symbolical of the one purpose which animated the Allied troops, and that it obviated the separate issue by each nation of its own war medal to allied forces which had served with them in their own territories. Each country designed its own medal, the stereotyped features being that each medal is bronze and has on the obverse the figure of Victory, and on the reverse the inscription "The Great

War for Civilisation." The ribbon is coloured in the form of two rainbows joined together, symbolising the calm after the storm.

The following are some of the chief decorations and medals issued since 1910:—

BELGIUM.—Service. War medal, bronze, shaped like a bell or a label. Ribbon, yellow, red edges with inner separation line of black. Victory medal, Obverse, figure of Victory; reverse, Arms of the Allies.

FRANCE.—Personal. Croix de Guerre. Established 1915. Bronze cross with crossed swords in angles. Ribbon, green, seven narrow red stripes. *Service.* War medal. Bronze. Ribbon, red and white stripes. Clasp, " Engagé volontaire " to non-conscripts. Victory medal. Obverse, figure of Victory; reverse, inscription (see above).

GREAT BRITAIN.—Since 1910 the following have been issued: *Personal.* Distinguished Service Medal (Navy), 1914. Ribbon, blue, two white bars in centre. Military Cross (Army), 1914. Ribbon, white, central purple stripe. Military Medal (Army), 1916. Ribbon, dark blue, in centre two crimson and three white alternate stripes. Distinguished Flying Cross, 1918. (Royal Air Force). Ribbon, violet and white broad diagonal stripes. Distinguished Flying Medal, 1918. (R.A.F.). Ribbon, violet and white narrow diagonal stripes. (The above two decorations are for active flying against the enemy.) Air Force Cross, 1918. (R.A.F. and civilians.) Ribbon, red and white broad diagonal stripes. Air Force Medal, 1918. (R.A.F. and civilians.) Ribbon, red and white narrow diagonal stripes. (The above two decorations are for distinguished service to aviation in actual flying.) Recognition Medal. Silver and bronze medals were issued to allies who had rendered service to British Prisoners of War and others behind the enemy lines. Ribbon, yellow; red, white and black edges, blue central stripe. *Service.* Naval General Service Medal, 1915. Ribbon, white, crimson borders and two crimson stripes in centre. African General Service Medal. New issue 1916. Ribbon, black, green and yellow (never seen without a clasp). 1914 Star. Bright bronze. Ribbon, red, white and blue, shaded and watered. Clasp, " 5th Aug.—22nd Nov. 1914." 1914–5 Star. Similar to above, same ribbon, no clasp. War Medal, 1919. Ribbon, orange, narrow stripes of white, black and blue at each edge. Clasps sanctioned for navy, but not for army. Victory Medal. Obverse, figure of Victory; reverse, inscription (see above). Oak leaf on ribbon for one or more mentions in despatches. Mercantile Marine War Medal. Bronze. Ribbon, green and red, separated by narrow white central stripe. Territorial War Medal. Bright bronze. Ribbon, yellow, two green stripes. Special Constabulary Long Service Medal. Bright bronze. Ribbon, red, white and black. Clasp, " The Great War, 1914–1918." General Service Medal (Post War). Ribbon, purple, with green central stripe; clasps for service in Persia, 'Iraq and Kurdistan.

ITALY.—Service. War Medal. Bronze. Eighteen stripes of red, white and green. Clasps bearing date of each year. Victory. Conforms to standard specification.

JAPAN.—Service. Victory Medal. Obverse, a Japanese figure of Victory.

RUMANIA.—Service. War Medal. Cross in black bronze, relieved in bright bronze. Ribbon, green with three blue stripes. Victory Medal. Conforms to specification.

UNITED STATES.—Personal. Distinguished Service Cross, Army, 1918. Ribbon, blue; red and white edges. Distinguished Service Medal, Army, 1918. Ribbon, white; red edges, narrow blue separation line. Distinguished Service Medal, Navy. Ribbon, blue, narrow yellow central stripe. Navy Cross. Ribbon, blue, narrow white central stripe. *Service.* Victory Medal. Bright bronze. Obverse, figure of Victory; reverse, design with shield and fasces and names of Allies. Battle Clasps are awarded. The only Service Medal issued by the United States to commemorate service in the World War. (A. V. W.-H.)

MEDICAL EDUCATION (*see* 18.23a).—A sound general education is necessary for the medical as for all other professions.

I. IN GREAT BRITAIN

In Great Britain before admission to a course of training a boy or girl is required to show in an examination of matriculation, character and standard that he or she has acquired a respectable knowledge of English, a language other than English, mathematics and some other school subjects of the candidate's own selection. Latin is no longer exacted by the General Medical Council (G.M.C.) although in certain universities it is compulsory for students who desire to obtain a medical degree. But the ordinary school subjects are not the only instruments available for the development of intelligence. Physics, chemistry, biology, when well taught also strengthen the mind and develop the faculty of observation which for a doctor is of paramount importance.

The General Council of Medical Education and Registration does not determine directly the requirements of the various licensing bodies, but exercises a measure of control over the doctor's training by deciding the conditions precedent to registration, first as a medical student and finally as a qualified practitioner. Since 1922 the G.M.C. has required an examination in physics and chemistry be passed by him before registration. The gain is two-fold. His school work more efficiently prepares the boy for his profession, and more time is made available in the brief five years, which is the most that can be exacted as a minimum between registration as a student and registration as a qualified practitioner. The council also allows the student to pass the examination in biology immediately after registration. The curriculum recognised as medical carries the student through a succession of stages which merge insensibly one into the other, until his accumulated knowledge and steadily increasing skill justify the conferring upon him of a degree or diploma which admits him to all the responsibilities of medical practice. It is impossible to over-emphasize the statement that the several steps " merge." They are not stepping stones. No subject is left behind when the passing of an examination qualifies a student to approach the next. The examination tests his fitness to approach subject B whilst still carrying forward subject A.

Stages of the Education.—These stages may be defined as (1) The study of the structure of the body and of its behaviour in health, anatomy (*q.v.*) and physiology (*q.v.*), to which two years are assigned. (2) The study of the behaviour of the body when perturbed by abnormal conditions, by malformations, by injury (*see* PATHOLOGY), by the invasion of parasites (*see* PARASITOLOGY) ranging from ultra-miscroscopic " germs " (*see* FILTER-PASSING MICROBES) to intestinal worms, an extension of physiology into the domain of disease. (3) The study of physiological changes which result from the administration of various chemical substances, " drugs," already anticipated by the study of the " drugs " which, in health, various organs pour into the circulation, internal secretions (*see* ENDOCRINOLOGY). (4) The study of the possibilities of modifying the behaviour of the body, when diseased, in a beneficial way by administration of drugs. (5) The proper management of the body in health, preventive medicine. (6) The care of the sick and of women in childbirth.

At all periods medical education has been adapted to the knowledge and practice of the age. Since Pasteur revealed the true cause of the large majority of diseases—the invasion o the body by micro-organisms—the science of medicine may al most be said to have come into existence. Corresponding modi fications of the medical curriculum have consequently been called for, and many have been adopted—always with a certain lag. Since 1910 much has been done in adapting training to the new knowledge and new needs. An important change is the dis appearance from the curriculum of the subject known as *materia medica*, a subject which used to make a painful demand upon the student's memory. Long after the date at which doctors ceased to make up their own medicines, compounded of a variety of ingredients, with all the mystery of a professional secret, or wrote equally complicated prescriptions in Latin, incomprehen sible to anyone but a druggist, the student was required to know the methods of preparation and the composition of the drugs of the pharmacopoeia. He was also required to produce a certifi cate of having attended a course of instruction in dispensing at a hospital or with a qualified medical man or pharmacist. Modern pharmacology (*see* PHARMACOLOGY) recognises that the body's perturbations may be restrained by certain definite chemica substances, many of them produced synthetically. Of these th practitioner's armamentarium contains relatively few. Fo flavouring and colouring matters he no longer has much use.

The Object of Medical Training.—With the exception of th changes already referred to, developments in medical educatio are rather in the manner of presenting knowledge than in th selection of subjects to be studied. When so much of value mus be omitted, every subject included in the curriculum should b taught in the most practical way. It must be made a part of th practitioner's outfit, which he can never afford to lose. Hi knowledge of the anatomy of the living body must enable him to see its organs in their relation to one another as clearly as if it were transparent. In some degree dissecting room work has given way to surface anatomy and the study of models and frozen sections; although training in the use of scalpel and forceps is still the only means of acquiring dexterity in the surgeon's craft. In physiology, during the first year, the student is in most schools given more practical work than formerly. Beginning with the frog and passing on through isolated mammalian organs to the decerebrate mammal, he is brought in his second year more closely into contact with the human body. He learns to use methods and apparatus with which, later, he will investigate the physiological condition of the organs in disease.

The greatest changes have been introduced in the third and fourth years of the curriculum. Physiology has been extended into pharmacology, an ever-growing body of exact knowledge derived from the study, with instruments of precision, of the effects produced upon guinea-pigs and rabbits by chemical compounds of which some, like caffeine and morphine, are vegetable products, whilst others, such as phenacetin, have been prepared synthetically in the laboratory for the express purpose of modifying the behaviour of the body. When used to correct undesirable habits, these various chemical substances, with the apparatus which has been designed for the purpose of studying their effects, belong to the sphere of therapeutics (*q.v.*).

At about this stage in the student's training, bacteriology (*q.v.*), a science which is growing so rapidly as to be for the most part relatively new, claims his attention. The micro-organisms which cause disease present biological problems of the highest interest. Every medical man needs to be expert in the methods of making preparations for identification with the microscope (*see* MICROSCOPY), of preparing media and of cultivating the various organisms *in vitro*. And since the effects upon the fluids of the body which they induce can be recognised chemically, a new name, "bio-chemistry" (*q.v.*), is usually applied to the department of science in which ascertained facts are grouped together. To the physiologist and physician have been opened up the two provinces of serum and vaccine therapy and immunology (*see* IMMUNITY). Provision is made for teaching the principles of various kinds of drugless therapeutics, such as treatment with ultra-violet light (*see* HELIOTHERAPY) and with radium massage, and the demonstration of the results obtained in special clinics. Pathology (*q.v.*), formerly the post-mortem examination of patients the course of whose illness had been watched in the wards, has become more of a science. As experimental pathology, it is the study of the physiology of disease. Disturbances of function, their causes and progress, are followed by the same methods as if they were variations in the performance of the several organs during health. Autopsies confirm or modify views expressed during life regarding tissue changes which were taking place.

Clinical Units.—The most notable improvement in medical education made during recent years is the organisation of clini- l units. Physicians and surgeons still go round their wards at ated hours—usually in the early afternoon—followed by troops students to whom they point out the features of each case, expound the nature of the malady and explain the reasons for e treatment adopted. But no longer, as formerly, is the student dependent upon "walking the wards," attending lectures and reading about the illnesses of which the cases he has seen e illustrations. The clinical unit is a far more efficient training ntre. Its staff consists of a director and three or four assistants. Either the director himself or one of his assistants is a whole- me officer of the university. To the unit are assigned a number beds—usually 60 or 70—in suitable wards with adequate boratory accommodation in their near vicinity and an ample pply of apparatus for the examination of the patients and for sting their reactions. An out-patient department is included the unit. In short, it is a school in the sense in which a phys- ogical institute is a school.

Students examine chemically and microscopically the blood d excreta. They make every kind of measurement, and as the wards are open throughout the day they have the opportunity of seeing how patients should be treated, nursed and cared for in every respect. As the teachers of physiology, bacteriology, pharmacology and other subjects visit the clinic from time to time, the student learns under ideal conditions how all that he has been taught combines to fit him for his life-work, the care of the sick and their restoration as speedily as possible to health. When cared for by a clinical unit patients recover more rapidly than they used to do, and in consequence the efficiency of the hospital is increased.

The Former System Contrasted.—Until comparatively recent times students were required to attend a certain amount of hospital practice during their first two years, usually six months. This was a relic of the apprenticeship through which aspirants for admission to medical, as to legal and other professional guilds, were required to pass. In Britain, this tradition is obsolete at last. No longer is a student required, or even allowed, to listen to bedside disquisitions on maladies of which even the names may be unfamiliar, in terms which carry little meaning to his mind, or to watch the physical examination of organs of which he knows but vaguely the form and situation, and to hear of their perturbations before he knows how they function normally. Not until he knows how the body works in health is he shown how disease may disturb its harmony, or taught the remedial measures which should be adopted with a view to aiding nature to set it right. Too early contact with patients inevitably led to confused thinking and false inferences which had to be corrected by subsequent reading and observation and, it may be added, developed in the tyro a conviction that medical practice consists in "spotting" the disease and administering the drug which will "cure" it. The progressive opening-out of knowledge with the synchronous revelation of ignorance, which is the aim of the modern curriculum, avoids loss of time and secures the highest degree of qualification for the exercise of the medical profession which the limited period of training allows.

Post-graduate and Specialist Work.—As a result of the careful allocation of his time the modern student finds that he has less opportunity than his forerunners of paying special attention to any branch which may attract him. Diseases of the eye, of the throat, of the ear, of the nervous and other organs, are treated with sufficient fullness for the equipment of general practitioners, but not with the thoroughness necessary to make specialists. The student who proposes to specialise must continue his studies after graduation. An increasing number of graduates who do not propose to devote themselves to a single speciality, but wish to make themselves proficient in particular branches of their work, such as gynaecology for example, defer going into practice, or return from time to time to a medical school in order to keep abreast with advances in knowledge and technique. Post-graduation courses are more numerous and better organised than they were before the War, but they are not yet, in Britain, as complete or as intensive as they might be.

Other Countries.—In the universities of Canada and Australia and of most foreign countries, progress has followed the same lines as in Britain. A logical sequence of studies and their integration in the curriculum has been the reformer's aim. In Japan the sequence of studies is much the same as in Britain; but the minimal length of the purely medical curriculum is four years, following on a course in the preliminary sciences. French medical schools still adhere to the system which they regard as "natural." Their students are encouraged to attend clinics from the date of their inscription in the faculty, and the relegation of all lectures and laboratory work to the afternoons almost compels them to devote the mornings to attendance in the wards and out-patient departments.

BIBLIOGRAPHY.—For detailed information consult *Recent Advances in Medical Education in England*, a memorandum addressed to the Minister of Health by Sir George Newman, Chief Medical Officer; and *Medical Education, a Comparative Study*, by Abraham Flexner.

(A. HI.)

United States.—In 1900 there were in existence in America 160 medical schools, mostly in fact, if not in form, private ventures; even the few schools of high grade possessed meagre endowment and inadequate facilities. By a process of natural selection, the number of schools was rapidly reduced, having fallen in 1925 to 80, and there were grounds for the belief that this number would in the near future be still further reduced. The organisation, endowment and facilities for instruction showed a notable advance. In 1910 few medical schools actually controlled the hospitals in which their teaching was done. Subsequently there was a distinct tendency to give the university medical schools exclusive and adequate control of hospital facilities for clinical teaching and research. Harvard, Yale, Washington and other universities thus came into much more intimate relations with the hospitals in which the clinical staffs teach. The city of Cincinnati built one of the finest public hospitals in the United States and amended the city charter so as to give the University of Cincinnati (a municipal institution) complete control of the hospital for its medical school.

On the financial side, public opinion was brought to realise that the university school of medicine is an expensive enterprise, for which large investments must be made by the public in both facilities and endowment. Mr. John D. Rockefeller gave the General Education Board approximately $35,000,000 to be used primarily for the purpose of co-operating with institutions in raising large sums for the development of their medical schools, and the late Mr. Joseph R. DeLamar gave $5,000,000 each to the medical departments of Harvard, Columbia and Johns Hopkins. Upwards of $12,000,000 was raised for the establishment of a new medical department at the University of Rochester, Rochester, N.Y., and $8,000,000 was raised for the reorganisation of the medical department of Vanderbilt University, Nashville, Tennessee. Columbia University is building a new medical school, and the Presbyterian Hospital, the Sloane Hospital and the Vanderbilt Clinic are providing new clinical facilities for the use of the school, the whole involving a prospective investment of $13,000,000; so at Cleveland an admirable school and laboratory building has been constructed on a new site on which university hospitals are already being located. In this movement the state universities have participated—notably the University of Iowa, which is completing a new plant—laboratories and clinics—at a cost of $5,000,000. Many other endowed institutions also procured considerable sums for improved laboratory and teaching facilities.

In respect to organisation the main change in the period was the introduction of the full-time plan corresponding to the English unit system in the teaching of the clinical subjects. The aim and purpose of this movement are the same in both countries, but in neither had sufficient time elapsed to allow a final verdict to be passed on the merits of the system. The complete satisfaction of the Johns Hopkins Medical School in the working of this plan is shown by the fact that the system, which originally included medicine, surgery and pediatrics, has been extended so as to include gynaecology, obstetrics and ophthalmology. The system has also been adopted in the main clinical branches by the medical departments of Washington University (St. Louis), Yale University, Vanderbilt University, University of Chicago, University of Rochester, the medical clinic of Columbia University, the psychiatric, pediatric and obstetrical clinics of the University of Iowa and the neurological clinic at Harvard.

China.—Through a subsidiary board (the China Medical Board) the Rockefeller Foundation of New York has established in China a modern medical school. The Rockefeller Foundation has furnished funds amounting to $8,000,000 to build and equip the Peking Union Medical College, and in addition it was in 1921 supporting the institution on the basis of a budget for the year amounting to $500,000. The institution furnishes two years of pre-medical work, and intended to develop a four-year medical course. The China Medical Board also aids four other medical schools in China carried on by other organisations.

Belgium.—The University of Brussels had in 1921 planned a complete reorganisation of its medical department. The city, the state and the university co-operated in maturing plans for a modern teaching hospital, and new, well-equipped laboratories on a single site. (A. F*.)

MEDICAL LEGISLATION.—Since 1911 statutes have bee passed in many countries creating or reorganising the centr public health authority. The Ministry of Health for Englar and Wales created by the Act of 1919, took the place of the Loc Government Board with all its powers and duties and, as r gards public health, also those previously exercised by the Boar of Education and other departments. Power was further create to transfer from the Ministry duties which were not incident to health.

Ministries of Health have also been established in Canac (1919), the Union of South Africa (1919), Poland (1919 New Zealand (1920), France (1920) and Rumania (1923). Dept. of Public Health for the Commonwealth of Australia wa created in 1921, and a General Directorate of Public Health i Spain, by a Royal Decree of 1922.

Zymotic Diseases.—In Australia, New Zealand and the Unio of South Africa comprehensive regulations regarding the not fication and control of infectious diseases were included; simila regulations were issued in Austria (1913), the Straits Settlement (1915), Peru (1916), Chile (1918), Sweden (1919), Brazil (192 and Venezuela (1921). A Polish law of 1920 created the offic of Special Commissioner for dealing with epidemics, and a Frenc decree of 1920 instituted a mobile unit equipped with laboratories, etc., for instant dispatch to parts of the country sufferin from or threatened with a disease epidemic.

Vaccination.—By a law of 1914, vaccination against smal pox (*q.v.*) becomes compulsory in Siam whenever the healt administrator deems it necessary; in the Straits Settlement (1915) it is compulsory, and re-vaccination also can be mad compulsory in the face of danger; in France (1915) vaccinatio and re-vaccination can be made compulsory by decree, bu (1918) vaccination is compulsory for state officials. Chile (1918 has compulsory vaccination in the first, 10th and 20th years c age; in Venezuela (1921) there is infant vaccination and re vaccination every seven years, failure to comply barring fror a large number of employments. In Poland (1919) there i compulsory vaccination for infants, and again at seven years In Tunis (1922) vaccination against smallpox is compulsory and also against typhoid, cholera and plague, if there is dange of an epidemic. Uruguay (1923) has compulsory vaccination i the first six months, and again in the 10th and 20th years. A Polish law of 1920 makes vaccination against typhoid fever an cholera compulsory for doctors, nurses, employees at waterwork and for those engaged in other specified callings.

Tuberculosis.—Anti-tuberculosis legislation has been put int force in various directions. Tuberculosis schemes and th legislation involved are discussed in the article TUBERCULOSIS The Milk and Dairies (Consolidation) Act, 1915, provided, *inte alia*, for the registration of dairies and the inspection of dairie and herds; and prohibits the sale for human consumption c milk from a cow with tuberculosis or other specified diseases c the udder. The Milk (Special Designation) Order, 1922, of th Ministry of Health instituted the licensing of classes of milk namely, certified, Grade A (tuberculin tested), Grade A (non tuberculin tested) and pasteurised; and prohibited the sale c milk under a designation to which it is not entitled.

The Public Health Act, 1925, section 62, authorises a court o summary jurisdiction to order the removal to a suitable hospita or institution, of any person suffering from pulmonary tuberculosi in an infectious stage, when a source of danger to others, eithe from lack of proper accommodation or from failure to observ sanitary precautions. In Denmark, laws of 1912, 1918 and 191 made compulsory the notification of pulmonary and larynge tuberculosis by the doctor in attendance, who is also required t instruct those in charge of the patient as to sanitary precautions

A Japanese law of 1919 gives power to examine any perso whose calling might make him a source of transmission, to forbi the exercise of a particular calling by such, and to forbid o restrict trading in old clothes, old books and other articles which might carry infection. In Denmark, compulsory isolation of infectious cases is also empowered with certain limitations; anc laws of 1918 and 1919 provided for the use of public funds t support hospitals for tuberculosis, sanatoria and convalescent establishments. A French law of 1916 instituted public dispensaries for treatment and for giving instruction in anti-tuberculosis measures. A decree of 1920 laid down regulations for the establishment, working and supervision of sanatoria. An Italian royal decree, 1919, instituted a central anti-tuberculosis committee, and a Swedish royal decree, 1912, regulated subventions to hospitals for treating tuberculosis.

Venereal Diseases.—The English Venereal Diseases Act (1917) prohibits treatment by unqualified persons in areas to which it s applied, when gratuitous treatment has been provided and approved, and prohibits all kinds of advertisements of quack remedies for such diseases. In Sweden (1912) an affected person is obliged to obtain and complete medical treatment; the same applies to the Union of South Africa (1919), where it is also an offence for an infected person to follow certain employments, or to ngage such a person in the employment; and to Czechoslovakia, where an infectious person may also be removed compulsorily to hospital if necessary, and an examination by a doctor can be nforced where there is reason to suppose that a person is infected with such a disease. In the state of Rio Grande do Norte, Brazil, by a decree of 1921, a special service for the prevention of venereal diseases was created, and provision was made for action gainst charlatans and for diffusing information regarding modern methods of avoiding the contagion. In Italy, a royal decree, 923, approved of regulations for the prevention of venereal diseases, including the examination and treatment of prostitutes. A Danish law of 1922 obliges a person suffering from venereal disease, in a stage when it may be communicated or transmitted, o inform the other party to a proposed contract of marriage, nd this party must be instructed by a doctor before contracting. The parties must make a declaration of freedom from such isease. The same procedure must be adopted if one of the parties uffers from epilepsy. When there is reason to believe that one f the parties may have disease or weakness of the mind such arty must present a medical certificate of mental health and make a declaration as above mentioned.

Housing.—The British Housing Act, 1925, *inter alia*, makes a duty of the local authority and the medical officer of health o inspect houses, prohibits the erection of back-to-back houses, nd gives power to close and demolish houses deemed unfit for uman habitation. The Public Health Act, 1925, gives a local uthority power to cleanse, disinfect or destroy articles infested ith vermin in dwellings, and to oblige a landlord or tenant to eanse the dwelling; powers are granted for cleansing of the erson also. A Belgian law of 1919 instituted the National ociety for Housing, amongst its powers being that of destroying nhealthy dwellings; a revising law of 1921 gave power to expropriate such houses and sites as are required. Similar powers were ranted to authorities in France by a law of 1915. A law of 1922 odifies the laws relating to working-class dwellings. A Peruvian w of 1916 obliges landowners to remove and prevent conditions n their land which are deemed to favour the existence of malaria.

Infant Welfare.—The British Notification of Births (Extension) Act, 1915, extended the Act to areas in which it had not en adopted. A Belgian law of 1919 instituted the national ork for infant welfare. In France a law of 1917 provided financial help for necessitous women in connection with child-birth, d when the mother nurses the child assistance continues for a riod of 12 months. In Germany (1922) help is given to women the same circumstances, insured and uninsured. An English t of 1920 regulates the employment of children, young persons d women in industrial occupations; and a Peruvian law of the me year is a similar measure.

Food.—The English Public Health (Milk and Cream) Regulations, 1912, prohibited the addition of any preservatives to lk intended for sale for human consumption, any thickening cream or preserved cream or any preservatives to cream with s than 35% of milk fat; the only permissible preservatives in eam intended for human consumption are boric acid, borax, a xture of these, or hydrogen peroxide. By an order, 1917, no ore than 0·4% of boric acid may be added and the cream must be sold as preserved cream and labelled as unsuitable for infants and invalids. Public Health regulations, 1923, fixed the minimum percentage of milk fat in dried milk of various descriptions, and that of milk fat and total solids in condensed milks. Containers must declare the contents, and skimmed milk be labelled as unfit for babies.

Drugs.—Most countries have legislated to restrict the use of opium, cocaine and related substances. The English Therapeutic Substances Act, 1925, regulates the manufacture, sale and importation of serums, vaccines, salvarsan, insulin, etc. Other countries have legislated similarly. (R. Sc.)

MEDICAL RESEARCH.—Progress in medical research since 1911 can be subdivided according to the branch of medical science into which it falls most naturally. An arbitrary classification, however, has the drawback that many subjects might be discussed equally well under other headings than those in which they are presented.

ANATOMY

First place in this section must be given to the collections of specimens illustrating war injuries and diseases that have been formed by certain museums, notably that of the Royal College of Surgeons of England. Extending to many thousand specimens these collections present a picture of the medical and surgical effects of war in the widest sense, that has never been equalled. Other anatomical researches of note were upon the distribution of the absorbents from the lower intestine and upon the caeco-colic sphincter tract. The former offers explanation of many peculiarities of disease in this region and is of value surgically; the latter is a new conception, likens the tract in question to the stomach and supports this contention by numerous references to several species of lower animals.

PHYSIOLOGY

Hormones.—Bier found reason to believe that a chemical stimulus (hormone) secreted by the retina initiates the formation of the lens in the larva of Triton, and that a hormone formed from bone-marrow underlies repair of bone. From this he argued that repair in general is dependent upon special hormones formed at the seat of the injury according to the type of tissue needing repair. The part played by the nervous system in repair still remains obscure.

Shock and Blood Transfusion.—A large amount of work was done upon shock and allied conditions. Shock is of great complexity but sudden removal of large quantities of fluid (blood) with the resulting disturbance of the circulation is a fertile cause. In correspondence with this, treatment by transfusion (*see* BLOOD TRANSFUSION) is of the greatest value and the methods of transfusion as well as the substances to be used were made the subject of numerous inquiries. Broadly speaking, for surgical shock and loss of blood by haemorrhage, injection of solutions of gum arabic are of great value, particularly if a small amount of glucose be added. Volume of injected fluid and rapidity of action are fundamental considerations, composition of the injected fluid is a matter upon which some latitude can be allowed, and use of blood is by no means obligatory. On the other hand where transfusion is performed for anaemia (*see* ANAEMIA) due to disease the character of the injected fluid is of first importance. Here, use of human blood is indicated and it is necessary, by careful examination of patient's blood and donor's blood to ensure that they belong to blood groups that are not mutually antagonistic.

Muscle Tone.—Physiological research of unusual importance was carried out (Sherrington, Magnus and others) upon muscle tone in the decerebrated animal by means of which tendon and other reflexes received a clearer explanation and afforded information upon many reflex postural responses to stimuli that appear to be voluntary. This line of research supplements experimental psychology, a branch of investigation that has made strides during the past two decades (*see* PSYCHOLOGY).

Respiration.—In the province of respiration, the relation of lactic acid and muscular exercise to the respiratory quotient has been investigated. Under exercise a lactic acid maximum of 0·3% in the muscles can be reached in about 30 sec., and this, or rather less, is the longest time that maximal exertions can be kept up. For these short maximal efforts there is reason to believe that carbohydrate alone is used by the muscles. Regulation of rhythmic respiration, from experiments carried out on cats, appears to depend upon the action of an inspiratory mechanism, the apneustic centre, at the level of the striae acusticae, an expiratory mechanism just below it, both of these centres being controlled by the pneumotaxic centre which is situated in the upper half of the pons. The actual stimulating agent is carbon dioxide.

Other Discoveries.—Very many subjects of inquiry must be passed over here, *e.g.*, discovery of rhythmic contractions of capillaries discovered by means of a special modification of the microscope; the behaviour of the spleen in poisoning by carbon monoxide; the action of lead upon red blood corpuscles; researches on bilirubin and urobilin and other pigments in relation to jaundice; on "buffering" of blood whereby the addition of a given amount of acid to blood is represented by a smaller change in reaction than would occur in simple watery solutions because of the existence of weak basic salts of carbonic and phosphoric acid, especially in the red corpuscles; and numerous investigations upon the action of insulin upon blood sugar and other constituents of the body as well as upon the interaction of insulin and other endocrine secretions.

Energy Expenditure.—Of more general interest is a research carried out upon the energy expenditure in sewing with a machine and hemming by hand. Careful measurements were made by means of the respiration calorimeter, but one most instructive result is that influenza exerts a depressant influence on energy output during rest when the patient has apparently recovered completely. In the case of the woman made the subject of measurement for five weeks after her apparent complete recovery, with the body weight returned to normal, energy expenditure was 4% lower than before the illness.

Tissue Culture.—Minute portions of chick and duck embryo heart have been cultivated in special glass cells. Under suitable conditions these portions of tissue live, grow and beat rhythmically in the culture medium for prolonged periods. If two portions of heart from the same species are placed in the same culture cell, each beats rhythmically at an independent rate until the masses fuse by growth when the beats become synchronous. If in the experiment the two portions are chick and duck, fusion by growth may occur but independence of rhythmic contraction persists (*see* also article TISSUE CULTURE).

As an example of information obtainable only by use of apparatus of extreme accuracy, Katz showed from a study of the curves of right and left intraventricular pressure and of aortic and pulmonary artery pressure that during normal experimental conditions right and left ventricular systoles and also their ejection phases neither begin nor end simultaneously and are, as a rule, of unequal duration.

BIO-CHEMISTRY

Insulin.—Much of the research falling into this category is concerned with the minute physical chemistry of the cell and therefore is of a fundamental character though hardly suitable for analysis in this place. An important practical result of laboratory work consisted in a simplification of the method of preparing insulin (*q.v.*) whereby a larger amount of the material of a higher potency was prepared from a given amount of raw material in less time and at smaller cost. Insulin forms a picrate when freshly ground pancreas is mixed with solid picric acid. The insulin picrate is extracted by means of acetone. By this discovery the cost of insulin treatment of diabetics has been reduced to one-third or less.

Vitamins.—Perhaps the most striking subject upon which biochemical investigations have been conducted during recent years has been that associated with accessory food factors (vitamins) and food deficiency diseases. Investigation of *beri-beri*, a nutritional disease associated with various nervous and paralytic symptoms, which occurs in man and can be induced i pigeons by feeding exclusively on polished rice, showed tha addition of a minute quantity of the milling was sufficient t prevent onset of the disease or cure it if in existence. The followed investigations into the causation, prevention and cur of scurvy and inquiries into the factors underlying growth of th body generally or of special systems (*e.g.*, bone in rickets). I cannot be said with certainty that rickets depends exclusivel upon absence of a special vitamin, for other factors, such as sufficiency of calcium and phosphorus, are necessary. Moreover sunlight, particularly the ultra-violet portion of the spectrum, i no less essential than due provision of the requisite vitamins fo production of that normal growth of the body of which norma growth of bones is but a part. As a result of the entire series o investigations upon accessory food factors, it may be said tha at the present time fat-soluble vitamin A and water-solubl vitamin B are regarded as being bound up with processes o growth and in addition there are anti-scorbutic and anti-beri-ber vitamins. These vitamins have been found in a great variet of animal and vegetable substances and the amounts presen vary within very wide limits. Their nature is unknown, and th most certain points in connection with them are the minutenes of quantity in which they are present and the potency of thei activity. As to their origin the suggestion has been put forwar on experimental grounds that they are compounds of high energ content produced by the influence of ultra-violet light, but thi hypothesis cannot be regarded as proved, indeed, some experimental observations are against it.

DIAGNOSTICS

Radiology (*see* RADIOTHERAPY AND RÖNTGENOLOGY).—On it diagnostic side, quite apart from the use of contrast meals an injections opaque to the rays, it is now possible to produce fa better radiographs with exposures measured in fractions of second than were possible at the beginning of the century wit exposures lasting minutes. This is largely due to the employmen of X-ray tubes in which the anticathode is a mass of tungsten heated by an independent current. For treatment, in order t approximate the wave-length of rays emitted by the X-ray tube to the wave-length of the gamma rays of radium, apparatus has been produced with a voltage in the region of 200 kilovolts. So far this type of apparatus is employed chiefly in the treatment of cancer. During the routine examination of large numbers o cases various anatomical peculiarities have been observed and some hitherto unknown morbid processes in bone have been described. Radiology has also proved useful in study of the physiology and pathology of the heart and great blood vessels, in pulmonary conditions, notably tuberculosis and bronchiectasis, in diagnosis of renal and biliary calculi, and it has been suggested as a means of diagnosis when perforation of a gastric or intestinal ulcer is suspected. The intentional injection of oxygen or air into the peritoneal cavity as an aid to radio-diagnosis has been employed somewhat extensively; it is stated to be devoid of risk and renders diagnosis of fluid or solid masses relatively easy. The use of radium (*see* CANCER; RADIUM) is confined chiefly to the treatment of cancer, but in some conditions of skin, *e.g.*, naevi, and in certain uterine conditions it has a well recognised applicability.

Therapeutic Use.—Other forms of radiant energy, sunlight (Heliotherapy), mercury-vapour quartz lamp, carbon arc, radiant heat, all of which depend upon the presence of ultra-violet light in the first instance and warmth in the second, are employed therapeutically to an increasing extent. A disadvantage under which X-ray and ultra-violet forms of treatment labour is the absence of a satisfactory standard of dose. Sabouraud's pastille is only reliable for "soft" radiation. The "skin erythema dose" is unsatisfactory because as used in France it is two and a half times as great as the "Hauterythemdosis" of the Germans. Even in German institutions the erythema dose varies between 285 R units and 1,120 R units (Martius).

Effects of Radiation.—Numerous researches have been made on the effects of radiation, particularly the gamma rays of radium, upon cells and tissues of the animal body, plants, seeds, bacteria, protozoa. It has been shown that the cell in division is more vulnerable than the cell at rest and that there exists a wide range of radiosensibility amongst animal cells and tissues. Amongst the most radiosensitive are the lymphocytes. So far as composite tissues are concerned the intestinal mucosa is highly radiosensitive, exposure of the abdomen to unduly heavy dosage eading to excessive formation of mucus, mucoid degeneration, ntestinal haemorrhage, paralysis of intestinal muscle, desquama-ion of large tracts of mucosa and death from toxic absorption. While there is universal agreement that, directly or indirectly, ays produce injurious effects upon cells there is doubt whether maller doses do not stimulate the activity of cells. Opinions are ivided upon the point, but the failure to observe any but in-urious effects may depend upon the fact that the experimenters ave not reduced the amount of radiation they employed to ufficiently low limits. In the case of Ascaris ova increase in rate f division was not observed until the amount of radiation re-eived by the eggs was reduced to that derived from about one en-millionth of a milligram of radium bromide for a period of bout 30 hours.

PATHOLOGY

Histology.—Morbid histology has been in some measure at a andstill, although during the War it was employed extensively striving to unravel the pathology of war nephritis, gas gangrene, gas poisoning and, indeed, of any novel pathological condition. Its most striking success was in reference to the mode of xtension of gas gangrene from the seat of infection. The action f the toxin secreted by the infecting bacilli extends along the uscle bundles far in advance of the bacilli themselves, produces assy changes of the muscle fibres correlated with a loss of con-actility that can be demonstrated on the operation table and a necessary precursor to advance of the bacilli themselves by ultiplication. These observations were the prelude to a radical odification of the surgery of the condition and a definite im-rovement in results.

Bacteriology.—In bacteriology (*q.v.*) a useful step was taken by e Medical Research Council in forming the national collection type cultures at the Lister Institute. Begun in 1920 it now ntains more than 2,000 living strains of bacteria, protozoa and ngi, available for workers in widely different lines of research. Experiments upon the conditions under which bacilli, particu-rly the sporing anaerobes of tetanus and gas gangrene, exert thogenic activity showed that if washed clear of toxin and oculated without contaminating substances they remained ert. Multiplication, followed by manifestation of the ordinary sease phenomena, occurred only if they were injected along th toxin (not necessarily their specific toxin) or with some lid particles such as lime or silica. In other experiments the esence of silica exerted an important influence on the multiplication of tubercle bacilli in the tissues.

Diphtheria.—Important observations were conducted in many untries upon the so-called Schick test as a means of diagnosing sceptibility to diphtheria (*see* INFECTIOUS FEVERS). If a nute quantity of diphtheria toxin, highly diluted, were injected tradermally in man there occurred a patch of redness locally out 2 cm. in diameter in certain persons, whereas in others e injection was without effect. Heating of the toxin destroys power of producing this effect. Further search indicated that those persons who are negative, diphtheria antitoxin is present the blood serum, whether naturally, or as the result of having ssed through an attack of diphtheria, or of gradual immunisa-n owing to the fact that the person is a diphtheria carrier. In hick-positive persons there is absence of antitoxin and there-e the injected toxin is not neutralised and produces its thological effect. Subsequent examination on a large scale owed that the reliability of the test was of a high order. The tural corollary is that during an epidemic all Schick-positive rsons should receive a prophylactic treatment with diphtheria titoxin. Later work showed that diphtheria "anatoxin," *i.e.*, xin detoxicated by addition of formaldehyde and exposure to a temperature of 37° C. for a few weeks, was equally efficaciou in producing immunity.

Scarlatina.—By a similar process of reasoning the two Dicks in America introduced an intradermal diagnostic test for scarlatina, the toxin being derived from broth cultures of a variety of haemolytic streptococcus found in the throats of scarlatina patients and believed by some to be the cause of the disease. So far the Dick test is not on such firm ground as the Schick test. Nevertheless some authors have expressed their view that the test is of much value in determining susceptibility or insusceptibility to scarlatina and that an anti-scarlatinal serum prepared by means of the haemolytic streptococci is in many instances efficacious in immunising the Dick-positive individual and rendering him negative on subsequent intradermal tests.

Tuberculosis.—A further extension of the principle has been applied in the case of tuberculosis (*q.v.*), but the work is still in its earlier stages and the time is not ripe for dogmatic statement. From time to time papers are published indicating that antibody formation is not a universal function of the tissues but that there are special sites for its formation. So far there is no consensus of opinion on the subject nor are the instances adduced sufficiently marked to be convincing but it is certain that variations occur in local resistance of the tissues to infection. The most recent suggestion is that antibody formation is a function of the reticular endothelial system.

Tularaemia.—A hitherto unrecognised disease was described by McCoy in 1912 when investigating ground squirrels in Tulare county, California, that had been attacked by a plague-like disease not caused by *B. pestis*. Since that time it has been found widely in the United States and was definitely recognised as affecting man in 1914. Since 1914 tularaemia has occurred in at least nine laboratory workers engaged on investigations with *B. tularense.* The micro-organism is an exceedingly minute cocco-bacillus and it is considered that infection in man was by inhalation or by a blood-sucking fly. Transmission from rabbit to rabbit occurs by the rabbit louse and the rabbit tick, neither of which bites man.

Dental Caries.—A bacillus (*B. odontolyticus acidophilus*) has been isolated from carious teeth and in pure culture forms sufficient acid to dissolve the enamel. Undecayed teeth placed in such pure cultures for a period of weeks show loss of enamel at spots and local growth of the bacilli along the dental tubules. Microscopically the appearance of this artificial caries is identical with that of natural caries.

Botulism.—Numerous papers have been published upon botulism, a form of severe food poisoning (*q.v.*) dependent upon an anaerobic bacillus (*B. botulinus*). The nervous system is profoundly attacked by the toxin, difficulty of vision, dilated pupils, ptosis and paralyses being among the earliest symptoms. The toxin differs from other toxins in being pathogenic when administered orally; it is absorbed in the stomach and upper duodenum. An antitoxic serum has been prepared and is useful in treatment. This form of food poisoning was originally associated with sausages but occurs in connection with a great variety of foods. Most of the recorded cases have occurred in America.

Spirochaetes.—During the War there occurred in Flanders amongst the men in the trenches a severe form of disease associated with jaundice and haemorrhage which was traced to a spirochaete similar to or identical with *Sp. icterohaemorrhagica*, which in Japan infects rats and is transmitted by them to man. The same organism was found in the rats infesting the trenches.

Syphilis.—In the case of another spirochaetal disease, syphilis (*see* VENEREAL DISEASES), Brown and Pearce succeeded in transmitting the disease to rabbits by intratesticular inoculation and showed the close resemblance of the pathological and clinical manifestations to those met with in man. By a prolonged series of experiments on rabbits Pearce answered in the negative the long debated question whether yaws and syphilis are manifestations of a single disease. Much work has been done on the Wassermann reaction. All doubts are not set at rest nor is the behaviour of the reaction completely understood, but it has stood the test of time and is considered of some diagnostic value.

In the investigation of spirochaetal diseases caution in deduction from experiment is shown by the fact that spirochaete-like bodies are to be found in the lateral ventricles of normal monkeys, rabbits and guinea-pigs. Only after animals that had been injected long previously with material from disseminated sclerosis (which is regarded by most authorities as of syphilitic origin) had been found to present these bodies in their lateral ventricles, was their existence in normal animals also discovered.

Typhus.—In typhus and trench fevers minute parasites were discovered belonging to the group now named Rickettsia. For a short time the relation of the Rickettsia to the disease was in doubt, but largely owing to the work of Bacot, an eminent entomologist who contracted typhus during his investigations and died therefrom, it is now recognised that both diseases depend upon the presence of varieties of Rickettsia, and that these parasites are conveyed from patient to patient by body lice. One of the most delicate manipulative operations ever attempted, and actually carried out with brilliant success by Bacot, was the filling of the rectum and intestine of lice with Rickettsia-infected blood by means of a fine capillary glass tube.

Bacteriophage.—An interesting phenomenon called after d'Herelle, its discoverer, has attracted much attention. When working with certain cultures of intestinal bacteria d'Herelle observed that on occasions culture apparently failed, the broth remaining quite clear. Subsequently he found that addition of a minute quantity of one of these clear fluids to a culture tube, cloudy with growth, was followed by clarification of the latter; as little as one part in a million was sufficient. He considered that he had obtained evidence of a filter-passing "microbe bactériophage" and obtained the phenomenon by successive culture from intestinal contents, sewage, soil extracts. This clarifying power is a property of leucocytes, tears, nasal mucus, eggwhite and other substances.

From the first the filter-passing microbial explanation met with opposition, many authorities regarding the phenomenon as being due to the action of an autolytic enzyme, or a catalyst causing the micro-organisms to produce autolytic ferments. Later, Fleming described a somewhat similar phenomenon by means of a special micro-organism that he isolated (*M. lysodeikticus*). This organism in thick suspension is in a few minutes completely dissolved by tears in a 1–9,000 dilution and using it as an indicator he found evidence of the lytic principle in nearly all tissues of the body, but not in urine, cerebrospinal fluid or sweat. In the vegetable kingdom he found it in the turnip alone. It is doubtful whether there is a single lytic substance or more than one. The essential difference between this and d'Herelle's phenomenon is that the former cannot be transmitted in series. Fleming therefore speaks of it as a "lysozyme," and points out that some bacteria are sensitive to lysozyme action and others not, thus raising the speculation whether the pathogenicity of bacteria may be determined by the absence of lysozyme.

Filter-Passing Microbes.—Since 1905 papers have appeared from time to time in medical literature on the "filter passer" or "filterable virus" (*see* FILTER-PASSING MICROBES). A series of morbid conditions is now recognised with more or less certainty as being due to a virus so minute that it passes through the pores of a porcelain filter, or in some cases is beyond the lowest limits of microscopic vision. Of these diseases rabies, vaccinia and perhaps, variola are the best known. In lethargic encephalitis and herpes evidence is tending in that direction but is not conclusive owing to the discovery that laboratory animals mainly used for this type of work (monkeys, rabbits) may under normal conditions present appearances in their brains that have been regarded as evidence of experimental transmission from man.

Dengue has been added to the list, while the so-called mosaic disease of the tobacco and tomato plants (*see* PLANT PATHOLOGY) is stated to be due to a filterable virus, and distemper in dogs may show a like origin. In addition a transmissible filter-passing virus has been recognised in the rabbit; at first this virus was thought to be the cause of varicella but it is now recognised to be the cause of a naturally occurring infection of the rabbit.

Gye and Barnard have described and photographed by mear of ultra-violet light, respectively, a filterable virus derived fror certain malignant tumours, following in this direction th pioneer work of Rous on chicken sarcoma. Finally, in the opinio of some authorities the cause of influenza (*see* INFLUENZA) is nc Pfeiffer's *B. influenza*, this being merely a usual concomitan but is in reality a filter-passing virus that has not yet been dete mined with certainty.

OBSTETRICS AND GYNAECOLOGY

Eclampsia.—The exact pathology of eclampsia has not ye been solved. Obata, as the result of injecting mice with extract of human eclamptic placenta, considers that it is an intoxicatio by placental poisons made possible by a weakening in its norma capacity of neutralisation on the part of the maternal blooc Treatment of the condition on conservative lines has recentl gained ground against more radical measures, and control of cor vulsions by hypnotics with venesection and administration c oxygen have replaced operative procedures. Under these cor ditions the previous mortality has been reduced by more tha 50 per cent.

Fibroids.—The chief direction in which change of view is tak ing place among gynaecologists is that of the treatment c uterine fibroids. The old method of curetting has given plac in large measure to hysterectomy, which in turn may be destine to give place to radiological treatment in a large proportion c cases. In several important gynaecological clinics on the Cor tinent surgical treatment of uterine fibroids is the exception i an uncomplicated case.

MEDICINE

Anaemia.—In pernicious anaemia (*q.v.*) it has been shown tha one of the cardinal features is an increase in the mean diamete of the red cells which is independent of the degree of the anaemi and persists through the course of the disease. On the othe hand anisocytosis increases with the anaemia. In the remission which occur naturally or after splenectomy, though the haemo globin may rise there is little change in the diameter of the re cells. In treatment transfusion has been found of little value but benefit has resulted in some cases from removal of a portio of the bone marrow from the tibia. Apparently removal of som of the bone marrow acts as a stimulus to regeneration of marrov and therewith of the blood cells that are needed by the body Purpura is described as being of two varieties (1) that which i dependent upon destruction of blood platelets; (2) that whicl occurs in anaphylactic conditions and is due to direct injury c blood vessels. In the platelet variety a blood platelet antiserun has been prepared and is of therapeutic value.

Heart Diseases.—Diseases of the heart and great blood vessel have been studied by means of the electrocardiograph anc numerous conditions, particularly heart block and those i which the nervous mechanism of the heart beat is concerned have been investigated. Systematic examination of recruits i whom cardiac symptoms developed during early training resultec in a clearer perception of those abnormalities of heart actior which were transient and of little importance as distinguishec from those which were significant of disease.

Cerebrospinal Meningitis.—Cerebrospinal meningitis (*q.v.*) anc lethargic encephalitis (*q.v.*) have received much attention. I cerebrospinal meningitis it has been shown that three, possibl four, different types of meningococcus occur and that antiserun treatment to be successful must be homologous. Epidemic could usually be traced to a carrier and the chance of thei occurrence was greater where men were confined in a relativel narrow space, *e.g.*, barracks. A special method of treating carrier by means of inhaling chloramine-T was instituted with som success. In the case of lethargic encephalitis, it appears probabl that the cause will be found to be a filter-passing virus.

Herpes.—In the case of herpes in rabbits and herpes in man including herpes zoster, it has been found possible to transmi keratitis and some other special conditions from animal t animal and man to animal by means of a filter-passing virus

Vhen this has occurred microscopical appearances are found in he nervous system apparently identical with those met with in ethargic encephalitis. The whole question, therefore, is in an nsettled condition.

Liver Cirrhosis.—An interesting observation is that a form of rogressive degeneration of the lenticular nucleus occurs which associated with hepatic cirrhosis. Since its first description by Vilson in 1912 over 70 cases have been described but the pathogical agent remains completely unknown, though there are ndications that the liver is the seat of the primary pathological rocess. Clinically the symptoms are chiefly cerebral and the epatic cirrhosis which is so constantly found at autopsy is sually latent.

General Paralysis of the Insane.—In the case of general aralysis of the insane, a form of treatment that has been dvocated is inoculation with benign tertian malaria which is en treated with quinine. Maniacal and early cases have been und to respond to this treatment best. Intelligence, articulaon, writing and equilibrium improve markedly, but defects of aracter and manners remain. Some cases may even be able return to responsible duties. Advanced cases merely remain ationary. The idea underlying this treatment is that the alarial parasites stimulate the body to the formation of irochaetal anti-substances.

Respiratory Diseases.—In the province of respiratory diseases, s poisoning necessitated urgent investigation from the comencement of 1915. An intense oedema was produced which ocked the finer air passages and in its minor degrees led to a despread bronchopneumonia. Variations were met with as e nature of the gas used was changed, but from the respiratory int of view at least the phenomena were fairly constant. In eumonia, experimental work on monkeys showed that four pes of pneumococcus occur and do not protect against one other.

Asthma.—Work on asthma has shown that in a large proporn of cases, if not in all, the disease is of an anaphylactic nature, intense reaction being produced in the bronchial mucous embrane of a person sensitised to some particular substance of otein origin. Determination of the particular substance in any lividual case may be lengthy, but if it be determined there is a ssibility of successful treatment by gradual immunisation.

Tuberculosis.—In tuberculosis (*q.v.*) two important methods treatment have been suggested. In one, an endeavour has en made to increase the antagonising cells in the body by eated irradiation of the spleen. This organ is a storehouse for nphocytes and it is known that the lymphocytic content of blood can be raised by repeated small doses of X-rays. The thod has not as yet a great following. The other method is administration of a gold salt $[Au(S_2O_3)_2Na_3]$ named "sanosin" by Möllgard, originator of the method. The underlying a is not purely chemotherapeutical for it is held that the poison- action of the organisms killed *in vivo* by chemical means is tralised by an antiserum. The experimental work was ried out in Denmark and has been confirmed and extended his country. Careful selection of cases must be made when lying sanocrysin to man as the reaction in pulmonary erculosis may be very severe, but with due precautions great efit may accrue.

Diabetes.—In the case of diseases of endocrine origin the outnding example of advance is afforded by the insulin (*q.v.*) tment of diabetes (*q.v.*). The pathology of the condition was ly well known but the great achievement of Banting and his aborators was that they succeeded in isolating the material ufficient quantity for therapeutic purposes. Numerous reches have been undertaken in the endeavour to simplify the tment but it still remains necessary for insulin to be injected avenously and repeatedly in severe diabetes.

oitre.—The relation of iodine to endemic and to exophthalmic re (*q.v.*) has been investigated. A close relation between the ılar condition of the thyroid and the amount of iodine has n demonstrated and it is held that relative or absolute deficy of iodine is the immediate cause of simple goitre however this deficiency may be occasioned. Treatment by internal administration of iodine has met with much success. Success has also been claimed for radiological treatment and for surgery in cases in which iodine and other medical treatment has failed.

Paratyphoid—Description has been given of a paratyphoid epizootic in a flock of sheep with a consequent human epidemic of paratyphoid (40–50 severe cases with four deaths) that occurred in the Essen district. *B. paratyphosus B.* was isolated from the sheep's flesh and from the patients' stools. It was not here a case of contamination but the sheep suffered from the same disease as the human beings.

A peculiar disease has been occurring since July 1924 among the fisher folk of the Frisches Haff, the great freshwater lagoon of East Prussia. Many suggestions were put forward as to its aetiology but finally it was traced to arsenic freely contained in the waste water of two cellulose factories which was pouring into the Haff in large quantities.

Racial Blood Indices.—On the basis of observed peculiarities of group II. and group III. red blood cells, another research would group mankind according to their racial blood index (*see* RACES OF MANKIND). Analysis of the large amount of material accumulated since 1919 suggests that so far as blood groups are concerned races fall into six divisions strikingly different in type. These six divisions are European, Intermediate, Human, Indo-Manchurian, Afro-South-Asiatic and Pacific-American. No better indication could be given, than this last example, of the wide range covered by medical research. (W. S. L.-B.)

MEDICAL SERVICE, ARMY (*see* 20.19).—An Army Medical Service (*service de santé*, Fr.; *Sanitätsdienst*, Gm.; *servizio sanitario*, It.; *eisei kimmu*, Jap.) is an indispensable technical branch of the military organisation. On its efficiency the man-power of an army to a great extent depends. Its duties include the care of sick and wounded, the prevention of disease and the preservation of health, the medical examination of recruits, the invaliding of men unfit for further service, the supply of medical and surgical material, the administration of military hospitals and the command, education and training of a personnel for all these purposes. In time of war the collection, evacuation and distribution of battle casualties and the strategical and tactical employment of a variety of medical units for these duties are additional functions of an army medical service.

Administration.—The army medical service of the British forces is administered by a director-general in the adjutant-general's branch of the War Office, with a staff for personnel and mobilisation services, for preparation of statistical reports and consideration of professional questions, and for the supply of medical and surgical material, together with two new directorates of hygiene and pathology which were instituted after the World War in consequence of the lessons of the War and of the scientific advances in the domain of medical research. The director-general also administers the nursing services and the Army Dental Corps, the former through a matron-in-chief and the latter through an inspector of dental services at the War Office. He is represented in commands at home and overseas by deputy directors and assistant directors with deputy assistant directors for hygiene and pathology. A similar form of administration exists in other armies. In the United States the surgeon-general controls not only the medical, dental, nursing and a new corps, the sanitary corps, but also the veterinary corps.

Advisory Boards.—These are composed of military and civil members and are associated with the British Army medical administration. They meet from time to time at the War Office for consideration of general professional policy, questions of hygiene and of pathological research, nursing services and the co-operation of voluntary aid in war.

Personnel.—The estimated peace establishment of the Royal Army Medical Corps in 1926 was 584 officers and 3,579 other ranks. They serve in all stations at home and overseas where there are British troops, including India. Their work there is supplemented by assistant-surgeons of the Indian Medical Dept., formerly the Indian subordinate medical department, and by natives of an Indian Hospital Corps, formerly the army hospital corps and army bearer corps, who with soldiers trained for hospital duties from combatant regiments formed the subordinate staff of British military hospitals in India before the War. A separate body of officers, the Indian medical service and sub-assistant-surgeons of the Indian Medical Dept. served until the World War with Indian regiments and in regimental hospitals under much the same conditions as the British regimental medical services of earlier days. Since the World War, station hospitals for Indian troops have been instituted.

FIG. 1.—Diagram of the organisation of Medical Services, from a corps front of three divisions in an army to a sea base.
(From "History of the Great War" [Medical Services], Vol. II. By permission of the Controller, H.M. Stationery Office, London.)

The army dental corps, with an establishment of 71 dentists, is estimated to provide one dentist for every 600 recruits or for every 1,500 troops in a command. (*See* DENTISTRY.)

Queen Alexandra's Imperial Military Nursing Service (Q.A.I.M.N.S.) has an establishment of 270 nurses and the Queen Alexandra's Military Families Nursing Service (Q.A.M.F.N.S.) an establishment of 91 nurses. They serve in the larger military and families hospitals at home and overseas, except India.

Territorial Army Royal Army Medical Corps.—The personnel is organised in peace to provide a regimental service, one field ambulance for each division of the Territorial Army, eight casualty clearing stations, three general hospitals and eight sanitar sections. These are field service units and form a cadre for th training of the R.A.M.C. (T.A.). Previous to the World War th Territorial Force had three field ambulances, one casualty clear ing station and one sanitary section for each division, togethe with 23 general hospitals. The reduction therefore in Territoria Army R.A.M.C. units since the War has been considerable.

Military Hospitals Reserve.—An establishment of 2,000 othe ranks is organised to provide trained personnel to staff militar hospitals in England on the outbreak of war when the regula Royal Army Medical Corps personnel is withdrawn, and t furnish reinforcements for an expeditionary force.

Service.—The number of medical officers (1924) was 939, c dentists 155, of nurses 675 and of veterinary officers 124. I continental armies with conscript service the fixed establish ments for medical services cannot be computed for purpose c comparison on the same basis as those of the British and Ameri can voluntary armies.

Training.—Officers of the R.A.M.C. attend preliminary an post-graduate courses at the Royal Army medical college, an military training with the men at the R.A.M.C. depôt at Alder shot, where there is also an army school of hygiene. In Americ an army medical centre was opened in 1923, at Takoma Par near Washington, District of Columbia. It consists of schoo for the training of the medical, dental, nursing and veterinar corps. There is also a medical field service school at Carlisl Pennsylvania, and a school of aviation medicine at New Yor In Italy, there is an army medical school at Florence, and i France, at Lyons, in addition to the post-graduate school a the Val-de-Grâce, for student candidates.

Military Hospitals.—In the British Army, military hospital and small depôt hospitals are established in all commands. I America, there are garrison hospitals and eight large genera hospitals, similar to some of the larger military hospitals i England. In continental armies there are also garrison hos pitals, but in France, military sections of the civil hospitals tak their place to a great extent.

Army Medical Stores.—In some continental armies most c the medical and surgical material is or was prepared in arm medical laboratories and factories. In Great Britain and Americ it is distributed from army medical stores, that for the Britis Army being at Woolwich.

War Organisation.—A regimental medical service, fiel ambulances, casualty clearing stations, general hospitals, cor valescent depôts, advanced and base depôts of medical store motor ambulance convoys, ambulance trains, hospital ship sanitary sections and squads, and mobile hygiene, bacteriologica X-ray and dental laboratories come into being for service with British Expeditionary Force on the outbreak of war; there ar equivalent units in other armies under different names an organisation. To complete their personnel on mobilisation th medical and nursing reserves are called up. For this purpos there is a regular reserve of R.A.M.C. retired officers and me liable to be recalled to service, a supplementary reserve c officers, a home hospital reserve of the St. John Ambulanc Brigade, the Territorial Army R.A.M.C. and the Voluntary Ai Detachments (under T. A. County Assn.) of the British Re Cross Society, the St. John and the St. Andrew Ambulanc Associations. There are also important reserves of the Q.A.I.M N.S. and the Territorial Army Nursing Service. But in a grea war, practically the whole of the country's medical resources ma be enrolled within the limits of age. In the World War, the peac establishment of the R.A.M.C. thus expanded to 15,000 officer and 120,000 ranks; while in the U.S.A. the medical service ex panded to 30,591 officers and 264,181 other ranks. A similar va expansion occurred in nursing personnel and in the number c medical units. Military hospital beds, for example, reached total of 637,746 for the British forces and 353,887 for thos of the United States.

The various units are distributed in the war zone, from fron to base, in divisional, corps, army and lines of communication areas of command, according to the nature of the functio or which they are organised. The regimental medical service onsists of an officer and four men of the R.A.M.C. with 16 men f the regiment as stretcher bearers and nine as sanitary detach-nent. In battle, a regimental aid post (*poste de secours*, Fr.; *Truppenverbandplatz*, Gm.; *posto di medicazione*, It.), to which hey collect the wounded, is established. Each division has three eld ambulances (the equivalent of the medical regiment of a J.S.A. division, the *groupe sanitaire divisionnaire* of the French, nd the *Sanitätsbattalion* of the German organisations). A field mbulance is composed of a headquarters and two companies, ach company consisting of a bearer and a tent division, repre-enting the bearer company and the field hospital respectively of he time of the South African War and previous equivalent nits of the continental army divisions. With a cavalry division here is an organised field ambulance for each cavalry brigade.

Working of the Systems.—In battle, the tent division opens an dvanced dressing station at a point to which its wheeled am-ulance transport can be brought, and a main dressing station urther back. The bearer company removes the wounded from ne regimental aid posts to the advanced dressing station, and ne transport brings them from there to the main dressing sta-on. The motor ambulance convoys (*section sanitaire auto*, Fr.), omposed of 50 motor ambulance cars each and with one convoy each corps, bring the wounded from the main dressing stations the casualty clearing stations (evacuation hospital, U.S.A.; *ôpital d'évacuation*, Fr.; *Kriegslazarett*, Gm.) which are estab-shed in the proportion of one to each division, at or near rail-ays and at the head of the lines of communication. From there, hen fit to travel, the sick and wounded are taken in ambulance ains to the general hospitals, which are units of 1,000 or less eds placed at sea bases or other convenient centres. Hospital ips transfer the patients to home ports, whence they are dis-ibuted to hospitals throughout the country.

Such is the normal system of collection, evacuation and dis-ibution of sick and wounded in a war zone. It is liable to odification according to circumstances and the nature of the rrain, especially as regards methods of transport by road, il, river, canal or air. It worked well in the World War, where e test was severe. During the battles of the Somme, for exam-e, the British field ambulances collected 316,073 wounded etween July 1 and Nov. 30 1916, including 26,675 in the st 24 hours; 304,285 were transferred to the base hospitals, and one day, July 6, 10,112 arrived in hospital ships at South-npton and Dover.

The mobile laboratories and advanced depôts of medical stores e usually placed with or near the casualty clearing stations. or sanitary duties a sanitary section, of 25 men, is allotted to ch division and base, and sanitary squads of five men each to nall posts, such as railheads. Their influence and that of edical research had remarkable results during the World War preventing disease. Enteric and typhus fever, the scourge of mies in past wars, became negligible quantities in the British d American forces, and fatal gangrene of wounds and trench ver, for long a cause of much inefficiency, were brought under ntrol. Indeed, the two outstanding features of the army edical service of the present day are its power of controlling sease and its power of systematically, rapidly and effectually inging battle casualties under life-saving surgical and hospital eatment.

In this beneficent work it is assisted by voluntary aid organisa-ons. Amongst all civilised nations there are national Red oss societies (*see* RED CROSS) organised as auxiliaries of their my medical services in time of war. They are of special value distributing voluntary gifts and comforts, such as are not sup-ed through official sources, to the various hospitals in the home rritory and in the war zone, in organising auxiliary hospitals d in various other activities. Those recognised by their vernments, together with the whole of the personnel and units the medical services of armies, are protected and become the cipients of special privileges under the Geneva Convention 1906, should they fall into the power of the enemy during war.

(W. G. MA.)

MEDICAL SERVICE, NAVAL.—In Great Britain the Royal Naval Medical Service is administered by the medical director-general, an officer selected from the list of surgeon rear-admirals. He is responsible to the Board of Admiralty for the efficiency of his department. The work of the medical department includes questions regarding the personnel of the Naval Medical Service, the supply of surgical instruments, drugs, medical material, etc., assessments arising from invalidings and claims for compensation, the hygiene and sanitation of ships, hospitals and establishments, preparation of estimates for the medical vote, nursing and sick-berth reserve forces and publication of the medical statistics of the navy.

Conditions of Service.—The medical director-general superintends all professional and administrative details of naval medical establishments and the practice of medical officers. Candidates for cadetships and for commissions in the navy are physically examined at his department. He also nominates the appointments of all naval medical officers which are submitted to the board for confirmation. The existing ranks date from 1919, and are: On entry, surgeon lieutenant; after six years' satisfactory service, surgeon lieutenant-commander; after six years' service in the latter rank, surgeon-commander, providing the necessary promotion examination has been passed; the senior ranks of surgeon captain and surgeon rear-admiral are reached by selection.

Until the outbreak of the War candidates were entered by competitive examination, but, owing to the lack of applicants since the War, these examinations have not yet been resumed, and for the time being officers are entered for temporary service, engaging for three years with the option of turning over to the permanent service if considered suitable. Officers senior to the rank of surgeon-commander do not normally serve afloat, but are employed in hospitals and depôts. Conditions of service, etc., are published in the official monthly *Navy List.*

All ships, except the smallest, carry medical officers, larger ones carrying two, In view of the fact that ships are frequently on isolated service, the medical officer, in addition to his ordinary medical and surgical duties, has to fulfil the function of medical officer of health, and consequently has to advise his commanding officer on all questions relating to the protection of the health of the crew, and suggest any measures considered necessary for this purpose. He must acquaint himself with the conditions of health prevailing at the ports the ship is likely to visit, and veto the introduction into the ship of any water or food likely to carry disease. It is his duty to instruct the ship's company in "first aid" and personal hygiene, with special reference to venereal diseases and the evils resulting from the abuse of alcohol. In fleets and squadrons the hygienic responsibilities are, as far as is compatible with efficiency, relegated to the senior medical officer of the flagship, who is designated the fleet or squadron medical officer as the case may be. This arrangement does not, of course, absolve individual medical officers from responsibilities concerning their own ships. The Royal Naval Dental Service was inaugurated in 1920, and is supervised by a dental officer of commander's rank attached to the staff of the medical director-general. The sick-berth nursing staff, instituted in 1884, has a complement of 1,100 highly trained men who carry out their duties both ashore and afloat.

Equipment and Hospitals.—The special accommodation which is allocated for the sick in all ships is termed the "sick bay." These places, in spite of the fact that all serious cases are, for their own comfort, transferred to hospital on the earliest convenient occasion, are specially equipped for the comfort of patients and for all medical and surgical contingencies. The larger ships have special operating rooms. Also, for the greater safety of the wounded in action, spaces are reserved in the most protected part of the ship. These are known as "medical distributing stations." The nursing on board is carried out by the sick bay staff. The naval hospitals are: Haslar, Chatham, Plymouth, Portland, South Queensferry, at home; and Malta, Hong-Kong, the Cape, Bermuda, Wei-Hai-Wei, abroad. In addition, there is a naval mental hospital at Great Yarmouth.

All these hospitals conform in every way to the most modern requirements of medicine, surgery and hygiene.

Auxiliary Services.—These include the medical officers of the Royal Naval Volunteer Reserve, Queen Alexandra's Royal Naval Nursing Service Reserve and the Royal Auxiliary Sick-Berth Reserve. The personnel of these services is called up for periodical training and would be mobilised on the outbreak of war.

Foreign Navies.—The organisation in the principal foreign navies is similar to the British. Medical officers of the French navy—instead of being selected from candidates qualified in the ordinary way, as is the practice in the British, Italian and Japanese navies—are professionally educated at special naval medical colleges, and subsequently hold purely professional titles of rank. Italian naval medical officers, in common with other non-executive officers of that navy, hold military in contradistinction to naval rank. The medical organisation in the Japanese navy is almost identical with the British.

The World War.—At the outbreak of the War the naval medical service was expanded by mobilisation of its retired, emergency and Royal Naval volunteer reserve officers. Later, a large number of temporary surgeons were entered for general service, and also medical students were taken in for service in destroyers under the title of surgeon probationers. Queen Alexandra's naval nursing service was more than trebled by the mobilisation of the reserve sisters and the sick-berth staff, supplemented by the naval auxiliary sick-berth reserve.

Except under abnormal climatic conditions, and during epidemics of influenza, the health of the navy during the War was remarkably good. This satisfactory state of affairs can be attributed to:—

(*a*) The careful supervision of the personnel by the medical officers and the strict quarantine precautions enforced.

(*b*) The care exercised concerning food, water and victualling arrangements, both in ships and establishments.

(*c*) Preventive inoculation against enteric fever.

(*d*) The comparative isolation of the fleets lessening the chance of venereal infection and abuse of alcohol.

(*e*) Lectures given to the men on personal hygiene.

(*f*) Measures taken to lessen the monotony of ship life in war time.

Casualties.—As compared with land warfare, the number of men killed outright in action was striking, and this, combined with the numbers of deaths from immersion, made the ratio of killed to wounded far higher in the navy than in the army. For instance, at Jutland, out of 6,688 casualties there were 6,014 either killed or drowned. The higher proportion of fatal wounds was due to the conditions of modern warfare—explosion of large shells in closed compartments. In comparison with the wounds in the trenches, where the clothing and skin were ingrained with filth, wounds in the navy were less disposed to become septic. Burns formed a high proportion of the casualties, and were chiefly caused by the ignition of our own cordite or from the momentary flash of a high explosive shell in a confined space. A considerable number of casualties arose from gas poisoning, caused by the explosion of shells, the most lethal factor in these cases being nitric oxide gas. (G. L. B.)

United States.—In 1926 the Medical Corps of the U.S. Navy consisted of 38 medical directors, 4 of which had the rank of rear-admiral and 34 of captain; 66 medical inspectors with the rank of commander; 320 surgeons, with the rank of lieutenant-commander; 217 past assistant surgeons, with the rank of lieutenant; and 147 assistant surgeons, with the rank of lieutenant (j.g.). The Dental Corps consisted of 66 dentists, with the rank of commander; 71 past assistant dental surgeons, with the rank of lieutenant; and 22 assistant dental surgeons, with the rank of lieutenant (j.g.).

The medical and dental officers are admitted to the corps after passing satisfactory examinations and as vacancies occur. Above the rank of lieutenant-commander promotion to each grade is by selection and examination. All medical officers receiving their appointment to assistant surgeon are given a course at the Naval Medical School in Washington, after graduation from which they receive their assignments to different posts of duty, either on board ships, at naval hospitals as internists or at other naval bases. The health and hygiene of the navy personnel are entrusted to the medical and dental officers of this branch of the service. Fully equipped hospital ships with an efficient personnel and skilled medical officers, including specialists, accompany all large fleets.

The Hospital Corps consists of pharmacists, pharmacist mates, first, second and third class, and hospital apprentices, as well as a corps of trained female nurses who serve on special hospital ships and in hospitals ashore. The enlisted men in the Hospital Corps are given special training and instruction at the various pharmacist and pharmacist mate schools throughout the country. During the World War those members of the Hospital Corps who had enlisted or had been drafted into it were put through a special course of training in civilian hospitals. The Naval Medical Reserve is composed of officers taken from civilian life and from among ex-naval medical officers. They receive a certain amount of training each year, are examined annually, and are promoted according to precedence, as in the regular service. They are ready to be called upon in any emergency.

The surgical instruments, medicines and dressings are all supplied, in great part, from the Navy Medical Supply Depot in Brooklyn, New York, and from the Medical Supply Depots in Mare Island, California, and Canacao, Philippine Islands. The entire Naval Medical Corps is under the direct supervision of the surgeon-general of the U.S. Navy, who is appointed by the President for this duty, for a term of four years, after which he may be reappointed. This duty carries with it the rank of rear-admiral.

3,093 commissioned officers of the Medical Corps of the U.S. Navy served in the World War, together with 24,587 enlisted men in the Hospital Corps. (C. C. B.)

MEDICINE, GENERAL.—Since 1910 the progress of medicine has been much influenced by the four years of the War, which, while interfering with steady research, brought with it urgent problems, caused diseases previously rare or unrecognised to become matters of common knowledge, and produced epidemics on an enormous scale, thereby calling forth much investigation and new knowledge.

Influence of the World War.—Trench fever and a special form of kidney affection, called trench nephritis, were practically new diseases; and the serious condition of epidemic (lethargic) encephalitis (*q.v.*), though it may have existed previously, for the first time became common and was recognised during the War. Certain industrial forms of poisoning, namely of trinitrotoluene among munition workers, and of tetrachlorethane among aeroplane makers, were temporarily in evidence, and an impetus was given to research into the conditions modifying efficient performance of labour. Deficient diet caused scurvy, especially in 'Iraq, and other "deficiency diseases" came into evidence, especially in central Europe. Cerebrospinal ("spotted") fever became for the first time epidemic in Great Britain (*see* SPINAL MENINGITIS); as a result of the depressing conditions and the lowered bodily resistance, influenza (*q.v.*) became pandemic all over the world in 1918–9; and a fatal form of infective heart disease (*endocarditis lenta*) became much more frequent in discharged soldiers. A form of infective jaundice (*spirochaetosis icterohaemorrhagica*), formerly known as Weil's disease, became prevalent in Flanders, and its true nature, namely, an infection with an animal microbe, akin to that of yellow fever (*q.v.*) (*Leptospira icteroides*), was found in Europe to be identical with that described in Japan in 1914. Paratyphoid fevers (*see* INFECTIOUS FEVERS) A and B, though of course known before, became much more familiar during and after the War, and it may be noted that the distinction between the forms of enteric fever known as typhoid and paratyphoid was not recognised in the Boer War (1899–1902), when the disease exacted a relatively heavier toll than in the World War, when the troops were eventually extensively protected by T.A.B. vaccination. Dysentery (*q.v.*), as in past wars, became prominent, as did malaria (*q.v.*) in the eastern areas of the campaign. The influence of a Sanitary Corps in the prevention of disease among the Allied Armies was a noticeable feature (*see* MEDICAL SERVICE, ARMY). Much progress has also been made in the prevention of tropical diseases (*see* THERAPEUTICS and TROPICAL MEDICINE).

Mental Diseases.—The War provided a tremendous field for he observation of the mental perturbations commonly desig-ated as "shell shock," due to the psychical effects of long-con-nued bombardment, mental strain and anxiety, repression or e active forgetting of terrifying experiences, and of fear. Inci-entally it gave an opportunity for testing the opinion of the ore advanced followers of Sigmund Freud of Vienna, who, on e assumption that the sexual instinct is stronger than those self-preservation and of the herd, have increasingly tended to fer mental symptons akin to those of shell shock to the conflict sulting when some sexual experience had, in obedience to the onventional influences, been repressed and thus removed out the zone of consciousness. The value of Freud's contribution morbid psychology (*see* Psycho-Analysis) in the conception mental conflict resulting from the active forgetting or repres-on of unpleasant experiences is undoubted, but to refer them ainly to sexual causes was shown by war experience to be too arrow a view, and the treatment by psycho-analysis and inter-etation of dreams, and the patient's "associations" aroused uch opposition. On the other hand curative measures on psy-o-therapeutic lines, such as sympathetic analysis, re-education d occupational therapy, met with success and approval (*see* sychiatry, Psychoses, Psychotherapy).

Orthopaedic Surgery (*q.v.*).—Orthopaedic surgery also made eat advances as the result of the numerous cases of injury ring the War, and remedial gymnastics and exercises have us been of great use in furthering recovery in such cases.

Preventive Medicine (*q.v.*).—The prolongation of life and dim-ution of infant mortality in Great Britain have both improved about 50% in the last half century, and in the United States America the average age at death has advanced from 40 in 55 to 58 years at the present time. This has coincided with proved conditions of hygiene and environment, and has stim-ated active measures in the prevention of disease—the ideal medicine. The establishment in 1919 of the Ministry of ealth in Great Britain was a far-seeing advance for the im-ovement of the national health and the prevention of disease e Therapeutics). In America regular periodic examination healthy, or supposedly healthy, persons has been begun, and statistical experience of life-assurance companies has already oved that this practice exerts a beneficial effect on the mor-ity of those adopting this course. The prevention of disease s been greatly assisted by the Rockefeller Foundation in New rk, which has undertaken a world-wide campaign with this ject on very broad lines through its International Health ard, its Division of Medical Education and its China Medi- Board. In 1913 the Rockefeller Sanitary Commission, nded in 1909 for the eradication of hookworm disease (*q.v.*), s incorporated as the International Health Commission lled the International Health Board after 1916) of the then ently established Rockefeller Foundation, and since then has ried out campaigns against yellow fever (*q.v.*) in South Amer-, which have practically exterminated it and incidentally led Noguchi's discovery of the cause (*Leptospira icteroides*) of the ease, against malaria (*q.v.*) and tuberculosis (*q.v.*) (*see* also erapeutics). In connection with the National Insurance (1911) the Medical Research Committee (now Council) s created, and research workers have been financed and an rmous impetus given to the advancement of medicine and so the diminution of disease.

ndustrial Health.—The special conditions bearing on health factories and industries, particularly the dangerous trades, e attracted specialised attention, particularly in America, ere a School of Industrial Medicine has been instituted in nection with Harvard University.

nsanity.—The prevention of insanity by early treatment in chiatric clinics, usually attached to general hospitals and n part of the neurological department, has been an important in the prevention of mental disorder (*see* Psychiatry). It onnected with the social service and after-care movements. 1908 the American Council of Mental Hygiene was founded, 1918 a similar council was started in Canada, in 1920 the French League of Mental Hygiene was inaugurated and in 1922 the British National Council for Mental Hygiene was established. This is evidence of the awakening interest in health of the public at large since the War, as is also shown by the Society for the Prevention of Venereal Disease, the League of Health and the British Empire Cancer Campaign.

Comparative Medicine.—The increase of experimental research has been followed by the study of comparative medicine and pathology, whereby human and veterinary medicine may mutually help and benefit each other; an Institute for research in the pathology of animal diseases and a professorship were established at Cambridge in 1923, and the study of experimental epidemics has been undertaken in laboratories at the Rockefeller Institute, New York, and at Manchester.

Statistical Methods.—Biological, anthropological and statistical methods are now being more formally utilised in medicine than in the past, and exact measurements and skilled calculations are being employed. An individual's constitution, or "the aggregate of hereditary characters, influenced more or less by environment, which determines his reaction to the stress of environment" (G. Draper), was present to the mind of Hippocrates and others, but the rise of bacteriology diverted attention from the internal to the external factors of disease. Anthropological measurements, formerly used for the recognition of the racial characters of mankind, have now been applied by Draper of New York to patients suffering from certain diseases, and the data thus obtained analysed by biometrical experts.

Applied Physiology.—Applied physiology was extensively developed and utilised during the War, for example in aviation, the transfusion treatment of surgical shock and haemorrhage, and the relief of gassing, and has advantageously been continued since on other lines, such as ventilation, the effects of sunlight and ultra-violet rays on bacteria, infections, general health and rickets (*see* Public Health). Following on the established value of open-air treatment of tuberculosis and other infections, the beneficial influence on bodily resistance induced by sunlight (heliotherapy) and ultra-violet rays has been utilised. Heliotherapy (*q.v.*), practised for 20 years at Leysin by Rollier in surgical tuberculosis, has been adopted in Great Britain. Sunlight prevents and cures rickets, and its relation to the anti-rachitic vitamin D is an addition to knowledge, possibly of potential importance in connection with other "deficiency diseases." Ultra-violet rays act on a complex alcohol, cholesterol, present widely in the body and also in the skin, so as to confer on it the anti-rachitic action of the vitamin; they also raise the amount of calcium, iron, iodine and phosphorus in the blood, increase its bactericidal power and accelerate the healing of wounds. The tungsten-arc and mercuric-vapour arc lamps are employed to provide artificial ultra-violet rays. Diathermy or the application of a special form of intensive heat has been employed in cancer, pneumonia and other infections (*see* Electrotherapy).

Biochemistry.—Closely associated with applied physiology, of which it is really a part, *biochemistry* (*q.v.*) has developed out of physiological chemistry and has risen rapidly to an authoritative position. At Cambridge the Sir William Dunn trustees have built and equipped a fine institute and endowed the professorship held by Sir Gowland Hopkins, who has 40 advanced students carrying out research under his direction. The Rockefeller Foundation, New York, has provided similar laboratories at Oxford and University College, London.

Metabolism.—Biochemistry is specially concerned with the changes always going on in the body and described by the name metabolism. The basal metabolism means the average minimal chemical changes compatible with life taking place in the body during complete rest and when food is not being digested and absorbed, and corresponds with the minimal heat-production 18 hours after a meal of a mixed dietary—the working expenses, so to speak, of the resting body. This is estimated directly by measuring by respiratory calorimeters the heat evolved, or indirectly, and more easily in practice, by chemical analysis of the respiratory exchange, and has been shown to be remarkably constant in normal conditions. In disease the metabolic rate may be altered; for example, in myxoedema it is lowered and all the vital processes are on a lower plane; whereas in fever and exophthalmic goitre it is accelerated. In the last-named disease the condition of the patient can be judged by the degree of increase in the metabolic rate. Knowledge of the chemical processes underlying metabolism is rapidly growing in exactness.

Vitamins.—The recognition of the *accessory food factors* or *vitamins* (*q.v.*) has opened a new chapter in nutrition and in the causation and prevention of disease. They are present in food in minute quantities, which greatly contrast with their power, and are essential for health, growth, especially of bone and teeth, and in other ways. New knowledge of the effects of their absence and of the (deficiency) diseases thus caused has accumulated, but more may be anticipated. The vitamins each have their special actions; one prevents scurvy (anti-scorbutic), others rickets (anti-rachitic or vitamin D), beri-beri or polyneuritis (anti-neuritic), and recently, it would appear, one is essential for normal reproduction, the absence of which, at least in female rats, produces sterility. Starvation, partial or complete, and an unbalanced diet entail a corresponding degree of avitaminosis and deficiency disease; war or famine oedema, which resembles the " wet " form of beri-beri, has been ascribed to a diet largely composed of cereal and deficient in protein food.

Blood-Chemistry.—From improved technique chemical examination of the blood for non-protein nitrogen (in kidney disease), sugar and gases, cholesterol, calcium, phosphates, chlorides and bilirubin has become a method of clinical laboratory routine and essential for correct diagnosis and treatment. Much work has been done on the hydrogen ion concentration of the blood and the conditions of (1) acidosis, or diminution in the alkali reserve of the blood, which occurs in two forms, ketosis, as in diabetes mellitus, and another due to retention of phosphates, as in renal disease, and (2) of alkalosis or alkalaemia in which the alkalinity of the blood is increased, as in forced breathing when carbonic acid gas is removed in unusually large quantities from the lungs. Alkalosis has, like a fall in the calcium salts and the poisonous effect of guanidine, been thought to cause a convulsive state—tetany, which forms part of the condition called spasmophilia seen in children.

Bacteriology (*q.v.*) has revealed the organism responsible for a number of diseases and so opened the way to specific treatment and the prevention of the infection. In the case of scarlet fever (*see* INFECTIOUS FEVERS), ascribed to haemolytic streptococci, G. F. and G. H. Dick have elaborated a test (the Dick test), analogous to the Schick test in diphtheria, whereby those susceptible to the disease can be detected and so artificially protected against it by an antitoxin. The recognition of tularaemia (due to a cocco-bacillus), a disease of rodents and transmitted to man by the bite of the horse fly, and of melioidosis also a disease of rodents and due to the *Bacterium whitmori*, in which the exact method of its transmission to man is uncertain, bear on the desirability of the closer correlation of the human with veterinary medicine. Invisible viruses or ultra-microscopic organisms, also called filter-passers (*see* FILTER-PASSING MICROBES), because they are so minute that they pass through the fine pores of a Chamberland or other filter, have attracted much attention and many diseases in man and animals are with a fair degree of certainty or probability ascribed to their agency.

Cancer.—The outstanding discovery of the ultra-microscopic organism of cancer (*q.v.*), which is active only in the presence of a " specific factor," by W. E. Gye and J. E. Barnard, opens possibilities of cure and prevention, for which the medical world has been at work for many years.

Bacteriophage.—D'Hérelle described a phenomenon, previously noted by Twort in 1915, often known by D'Hérelle's name, which he interpreted as the existence of an ultra-microscopic virus which lives as a parasite upon living bacteria and leads to their destruction and solution. The general opinion about the active substance responsible for these changes in bacterial cultures, and called by D'Hérelle the *microbe bacteriophage*, is that it is not an ultra-microscopic virus, but an enzyme or ferment produced by the undoubted bacteria themselves.

Protozoan infections (*see* PROTOZOOLOGY) are the cause of
number of diseases, such as yellow fever (*Leptospira icteroides*)
a form of infective jaundice (*Spirochaeta icterohaemorrhagica*)
rat-bite fever (*Spirochaeta morsus-muris*), and seven-day feve
in Japan (*Leptospira hebdomadis*), and probably sandfly feve
(*q.v.*) (a leptospira resembling that of yellow fever). Thus thei
prevention and the employment of curative antitoxins has bee
rendered possible.

Immunity (*q.v.*).—After a fever the individual usually become
immune and protected against another attack, this is acquire
immunity; the blood of such a person contains antibodies whic
antagonise the cause of that disease, and advantage has bee
taken of this to inject the blood serum of patients convalescen
from measles into persons who have not had the disease so a
to render them immune.

Anaphylaxis.—The reverse of immunity is hypersensitivenes
(anaphylaxis, allergy) which is shown by idiosyncrasies an
forms the underlying factor in asthma and other diseases spoke
of as " toxic idiopathies; " the substances responsible for th
symptoms can be detected by skin tests and the appropriat
treatment thus employed. Protein shock therapy is also em
ployed for asthma and chronic arthritis. The importance o
" focal infection " such as dental disease (*see* DENTISTRY), is no
much more fully recognised (*see* THERAPEUTICS).

Exact studies upon the chemical activities of bacteria now i
progress are beginning to throw light on the actions of toxins an
the chemical factors involved in immunity reactions.

Radiology (*q.v.*).—In radiology there has been a steady advanc
in the methods of diagnosis and treatment; technique has bee
elaborated and special methods have been introduced. Dye
opaque to X-rays have been employed in various direction
thus lipiodol has been injected into the bronchial tubes to dem
onstrate dilatation of their lumen, into the spinal column t
show the position of tumours, and even into the pregnant uter
to detect pregnancy. The condition of the gall bladder and th
presence of gall stones can be made evident by organic com
pounds of iodine and bromine (tetra-iodo-phenol-phthalein an
tetra-brom-phenol-phthalein), which after being taken by th
mouth are excreted in the bile and show up under X-rays (cho
ecystography). Injection of air into the peritoneal cavity e
ables a clearer X-ray picture of the abdominal viscera to
obtained. The skiagrams of the jaws, showing the presence
absence of infection of the apices of the teeth and of the sku
showing the condition of the sella turcica, have facilitated th
detection of focal sepsis and of pituitary disease respectivel
The improvement of technique has made advances in treatme
possible. By intensive X-ray exposures, following the Erlange
practice, the remedial therapy of deep-seated malignant growt
has been pursued. The radium treatment of cancer in positio
where the radium (*q.v.*) can be brought into close contact wi
the growth, is now carried out with increasing frequency, a
team work in this treatment of cancer of the uterus has bee
adopted in a number of hospitals. Side by side with advanc
in treatment the effect of X-rays on the tissue cells has been i
vestigated experimentally; the results have a very definite bea
ing on the methods and dosage employed in treatment, for t
destructive changes induced in the cells may give rise to gra
symptoms and even death. It appears that the action of X-ra
may set up secondary ultra-violet radiations in the tissues a
so cause severe changes.

Diseases of Function.—Functional disorder and the invest
gation of the early stages of disease, before the physical signs
gross structural changes appear, have attracted increasing atte
tion and are intimately wrapped up with the ideal of medic
science, the prevention of disease, proverbially a higher aim th
its cure. The first manifestation of disease is commonly disord
of function, which shows itself by symptoms unaccompanied
any structural change. Clinical observation was specially
rected to the detection of the earliest signs of disease by the la
Sir James Mackenzie, who in 1919 started team work in th
direction at the St. Andrews Institute for Clinical Researc
where laboratory tests were fully utilised as an aid to the caref

alysis of the patient's symptoms in an intense search for a real
derstanding of the familiar manifestations of undue fatigue,
laise, shortness of breath on exertion and pain. Tests for
order of function—some physical, as in disorders of the circu-
ory and respiratory organs, others chemical, such as exami-
tion of the blood and the ability of the organ to excrete coloured
es, for example, phenol-sulphone-phthalein, as in disease of
e kidney and the liver, others psychological, as in nervous dis-
ler—have recently been much elaborated and multiplied, and
l fair to facilitate more accurate and early diagnosis and treat-
nt on scientific lines.

Psychology (*q.v.*).—Experimental psychology, once regarded
an academic pursuit, has been the means of great economic
ing in industry, and the results of research work and tests
ve led to the introduction of rest pauses and other modifica-
ns, with the result of an increased output of work on the one
nd and benefit to the worker on the other. The Industrial
igue Research Board was set up during the War, and The
tional Institute of Industrial Psychology, established in
eat Britain after the War, ensures continued practical guid-
e for employers and employed (*see* INDUSTRIAL PSYCHOLOGY).

Endocrinology (*q.v.*). *Ductless Glands.*—The part played by
ductless or endocrine glands in the production of disease has
racted increasing discussion, especially on the questions (1)
he endocrine balance, meaning thereby that when one gland
disordered the equilibrium which normally exists between
m as a whole is upset, and (2) of the effects of disease of more
n one of these glands—pluriglandular disorder. This last
blem has on the one hand, from the difficulty of positive
of, aroused scepticism as to its existence, and on the other
d stimulated exploitation of commercial preparations of
nbined glandular extracts, the activity of which, as regards
e of the constituents, is open to serious doubt. The out-
nding advance in the medicinal use of endocrine preparations,
l indeed in therapeutics generally, is the introduction of in-
n (*q.v.*) for the treatment of diabetes mellitus (*q.v.*) (*see* THER-
UTICS).

The use of the endocrine preparations proved to be active is
sing out of the qualitative stage into the further one in which
y are being so standardised that the proper dose can be ad-
istered; this has been done for insulin, adrenalin, thyroid and
athyroid extracts. The interstitial cells of the testis ("inter-
ial gland") has attracted much research in connection with
influence on the secondary sex characters and in insanity.
perimental ligature of the duct of the testis (vasectomy) in-
ses the prominence of the interstitial gland and is followed
rejuvenation (Steinach), and with this object the operation
been often performed on men, as has grafting of testes of
n or chimpanzees (Voronoff) (*see* REJUVENATION).

ardiology and Circulatory Organs.—The work of the late Sir
es Mackenzie and Sir Thomas Lewis has so revolutionised
knowledge of the heart that there is a new cardiology (*see*
ART, DISEASES OF). By the electrocardiograph, which is
cially valuable in showing the condition of the heart muscle,
is showed that the extreme irregularity of the heart in cardiac
re, called by Mackenzie nodal rhythm, is due to auricular
llation; a circus movement instead of the normal contrac-
; it is in this condition that digitalis is of value. By means of
graphic methods the irregularities of the heart have been
sified.

ngina Pectoris.—Cardiac murmurs have been shown not
essarily to be of grave importance, and much work has been
e on angina pectoris. The symptoms—status anginosa—of
den obstruction of the coronary arteries which supply the heart
e been defined, and the cause of angina pectoris has been
rred to the failure of the heart muscle (Mackenzie), and to
ase of the first part of the aorta (Allbutt); in accordance with
last view operative division or removal of its nerves has been
ctised and found to relieve the pain, but not otherwise to
ct the disease. Bullets embedded in the heart-wall have been
oved, and a contracted (mitral) valve has been remedied by
ical measures (*see* HEART AND LUNG SURGERY).

Blood-Pressure.—The existence of high blood-pressure without kidney disease or hyperpiesia (Allbutt) has been established, and it has been suggested that table salt and, probably with more reason, guanidine raise, and that hepatic extract lowers blood-pressure. The state of the capillaries—microscopic vessels—their power to contract, and their influence on blood-pressure have been investigated and much new knowledge has been acquired. The prevention of rheumatic heart disease and the responsibility of tonsils and other sites of focal infection have received considerable attention both in Great Britain and in America.

Bronchoscopy.—In diseases of the lungs the trial of new methods of treatment has gone on, such as specific or chemical remedies, and the production of artificial pneumothorax (*q.v.*) (*see* THERAPEUTICS). As the presence of adhesions inside the chest interferes with the production of a curative pneumothorax, they have been divided by a cautery, the process being watched through a hollow tube, illuminated by electric light, passed into the chest (Jacobaeus' thoracoscopy). Bronchoscopy for the detection and removal of foreign bodies from the air-passages has, in the hands of Chevalier Jackson, become a fine art; the importance of an early removal of these bodies before they have set up destructive changes in the lungs, which in the past have proved obscurely fatal, has now been fully recognised. In the abdomen a method, laparoscopy or coelioscopy, by which the contents can be seen by an arrangement similar to that of thoracoscopy, has been employed; but neither of these difficult methods is likely to come into general use.

Fractional Test Meals.—The adoption of fractional test meals as a more exact method of determining the constitution and variations of the constituents of the gastric contents has, thanks to Rehfuss, superseded the single examination made one hour after a test meal. Absence of hydrochloric acid, a normal constituent of the gastric juice, has been shown to favour the onset of pernicious anaemia (*see* ANAEMIA). Aspiration of the bile by a duodenal tube, after Oddi's sphincter, which closes the lower end of the common bile duct, has been relaxed by a spray of magnesium sulphate, enables a microscopical, chemical and bacteriological examination of the bile to be made, and also does good by drainage in cases of infection and inflammation of the biliary tract.

Tests for Hepatic Efficiency.—The search for tests to estimate the functional capacity, or the way the liver is doing its work, has been carried on with energy, and a number of tests for the individual functions have been introduced; but no one test for them as a whole is satisfactory, and another difficulty is that the liver, like the heart and other organs, has a great reserve, so that it can, although much damaged, discharge its functions so well that tests do not reveal any failure of the compensated condition; this is especially true in chronic disease. By means of a blood test—the Hijmans van den Bergh reaction—obstructive jaundice can be distinguished from other forms.

Neurology.—The physiology and pathology of the nervous system has steadily progressed; the researches into the factors presiding over equilibrium and posture have yielded valuable information; disease of what is called the extra-pyramidal system has attracted attention; acute infections of the nervous system, acute poliomyelitis, encephalitis epidemica ("sleeping sickness") and cerebrospinal fever were more prominent in the conditions of war than before; much valuable scientific research into the method of actions of poisons on the nervous system has been carried out.

Panel Practice.—The conditions of medical practice in Great Britain were profoundly modified by the introduction, as the result of Mr. Lloyd George's National Insurance Act (1911), of the "Panel system," whereby 15,000,000 insured persons are now looked after by practitioners paid at a yearly rate of a sum which has averaged about ten shillings a year, paid partly by insurance contributions and partly by the state; this enormous undertaking is part of National Insurance and is under the control of the Ministry of Health. No one medical man is now allowed to have more than 3,500 persons on his panel. At the time of its initiation the panel system met with great opposition from the medical profession, but this collapsed, and on the whole the system works well, and is certainly an improvement on the old system of clubs. (*See* Health Insurance, Medical Aspects.)

Diplomas in Special Subjects.—The enormous advances in medicine have made specialism necessary and inevitable, and as evidence of the general recognition of this need diplomas in these special subjects are granted by the universities and licensing bodies. The General Medical Council in 1922 revised the regulations for one of the oldest diplomas, that of Public Health (D.P.H.), and ordained that two years, instead of one year as formerly, must elapse from the date of a candidate's obtaining a registrable qualification in medicine, surgery and midwifery before his admission to Part II. of the examination for diplomas in sanitary science, public health or state medicine. There are diplomas in psychological medicine, in tropical medicine and hygiene, in ophthalmic medicine and surgery and in laryngology and otology, and since the War the universities of Cambridge and Liverpool have given diplomas in radiology. (*See* Medical Education.)

Group Medicine.—The specialisation of medicine and the elaboration of technique prevent any one man from being master of the whole field of medicine, and accordingly there has been a tendency for men to combine in team work or group medicine, especially in America. A group of men expert in their own lines may work together or under a general physician or surgeon who, in consultation with them, correlates the collected evidence and comes to a final decision on the whole matter. These diagnostic clinics, which are exemplified by the Mayo Clinic, Rochester, Minn., are commoner in America than in Great Britain. They should have the advantage, from the patient's point of view, of providing for a fixed inclusive fee all the special examinations that may be necessary at a lower cost than in ordinary practice would be required for such a number of tests.

Bibliography.—*See* Bibliographies to the articles referred to in the text; also Sir T. C. Allbutt and Sir H. D. Rolleston (Editors), *A System of Medicine*, 9 vol., various dates. (H. Ro.)

MEDICINE, PRE-SCIENTIFIC (*see* 18.41).—The aim of primitive medicine, like that of primitive religion of which it at first formed an inseparable part, was to safeguard life, using the same means to attain their common end.

Main Causes of Disease.—Modern investigations reveal that savage races still attribute disease to three main causes:—

(*a*) The projection of some foreign substance into the body;
(*b*) The abstraction of something from the body;
(*c*) A sympathetic process operating on some part of the body or on some object that has been in contact with the victim.

As the supposed results are ascribed to the agency of men or spirits, their machinations have to be circumvented or their wrath diverted. Many practices illustrate these points. Thus suction is a common ceremony, performed upon the sick by many peoples, to extract the offending object. To discover the source of the evil, divination is employed. In many cases the native conception of the nature of the lesion associated with disease is very concrete. Thus certain Australian tribes look upon it as due to the abstraction of adrenal fat. In Melanesia it is held that removal of part of the soul, due to spirits, is the cause of many symptoms. The treatment of disease by savage folk can only be understood in reference to their pathological theory.

Trephining.—Among the most remarkable of the forms of treatment is trephining, which was performed from a very early date with stone implements before the introduction of metals. A decompressive trephining for epilepsy or other disorders of the brain, real or supposed, is still practised among the Aymaras of Bolivia and the Guichuas of Peru. The beliefs at the back of the process are still not clear.

Primitive Surgery.—The surgical measures of uncivilised man are not always as inadequate as might be supposed. Some savage folk have developed more than a rudimentary idea of bone-setting. Moss, fresh leaves, ashes or natural balsams are used to dress wounds, which, when poisoned, are treated by sucking or cauterisation. Among surgical instruments we note horns for cupping, a sharp thorn for opening an abscess, saws of stone and bone for amputations and special instruments for letting blood. The latter operation is very widely practised.

The Medicine Man.—The position of the medicine man
doubtless very similar among savages of to-day to what it
with early races. He exhibits a gradual differentiation from
priest. In Indonesia the medicine man is now quite disti
from the priest, but in Polynesia and North America the relati
ship is often so close that the two may be indistinguishable.

Survivals.—The remains of the savage's mode of treat
disease survive with peculiar persistence even in centres
Western civilisation. Belief in magic and in the efficacy
charms still plays a considerable part in the attempted prevent
and cure of many ailments in Europe and America. Thus,
instance, the mountaineers of southwestern Virginia and east
Tennessee believe that an iron ring, worn on the third fin
of the left hand, will drive away rheumatism. This pract
shows a persistence of the very ancient belief in magical prop
ties of the third finger and of iron. A modern English herb-doc
will peel the bark of an elm *downwards* if a cold has to be dra
down from the head, and peel it *upwards* if it has to be drawn
from the chest. Warts are rubbed at regular intervals with a g
ring. The persistence of colour as a significant factor in fo
medicine is shown by the use of red flannel as a bandage for s
throats and whooping cough, a case of sympathetic connect
between the redness of inflammation and the redness of mater
Finsen's red-light treatment to prevent pitting in smallpox
been said to trace back to the same folk-custom, employed
the case of the son of Edward II. In Ireland homeopathic d
tors give for jaundice yellow medicines, such as saffron, turme
sulphur, even yellow soap.

Egyptian Medicine.—Of the pre-scientific systems of medic
of the ancient civilisations, the best known is that of Egy
Ancient Egyptian medical treatment, chiefly magical, include
large number of traditional practices which had survived fr
very early times. For long the art of healing was in the hands
the temple priests. These men formed an organised body wit
sort of physician-in-chief at its head. They concentrated
hygiene and diet, advising abstention from many vegetable foo
especially beans and onions, the latter a supposed aphrodis
which also provokes thirst and tears, from mutton and po
from certain milks and from salt which produces drunkenn
and gluttony. On three days out of every 30, emetics or clyst
were to be taken. Among hygienic measures, dwelling hou
were to be kept clean and fumigated with resin and myrrh,
body was to be frequently bathed and suitably clothed a
gymnastic exercises were recommended. Ointments, potic
and poultices were in use. Among drugs were honey, incen
salt, cedar oil, sycamore bark, nitre, sulphate of copper, alum,
brains, liver, heart and blood of various animals, stag's horn a
oil of camomile for frictions. Fever patients were wrapped
woollen stuffs to promote perspiration.

Ebers Papyrus.—The Ebers papyrus mentions a number
symptoms and diseases (some difficult to identify) such as int
tinal worms, inflammation in the region of the anus, haem
rhoids, disorders at the pit of the stomach, fluttering of
heart, pains in the head, urinary affections, dyspepsia, angi
and about 30 different affections of the eyes. Among the ren
dies are blood-letting, sudorifics, diuretics, drugs to prod
sneezing, copper salts and oxymel of squills to produce vomiti
castor oil given in beer as an aperient and pomegranate seeds
the expulsion of worms.

Edwin Smith Papyrus.—The Edwin Smith papyrus, not
fully described, seems to suggest skill in surgery in advance
that of any of the contemporaries of ancient Egypt. It sugges
too, rather more anatomical knowledge than had hitherto b
considered likely among the Egyptians.

Statues of Healing.—On the purely magical level were
Statues of Healing. These were placed in rectangular bas
upon which texts and images were carved. The water t
flowed through the basins acquired magical properties throu
contact with the statues and thus became curative for all rep
bites. The water, either taken internally or used as a lotion,
all-sufficient; it was even unnecessary to repeat the ma
formulae carved on the garments of the statue or on the basi

nese remedies were therefore more especially used by the terate. Statues of *Horus on the Crocodiles* were the most dely-spread and most efficacious instruments of protection ainst and cure for the bites of scorpions, serpents and crociles, their use probably going back beyond the XIX Dynasty.

Coptic Medicine.—During the last few years our knowledge of medicine of the Copts has been considerably extended by publication oi a long and important text and by several nor finds. The Coptic material exhibits a rapid recession of ancient Egyptian element. Coptic *materia medica* reveals nistakable Greek and Arabic influences and magic is of ondary importance. The mouse, goat, wolf, hyaena, and other mals are all mentioned in prescriptions, but the greater num- of medicaments are of vegetable or mineral origin and lude, as in all early writings, emetics and purgatives. Eye-ubles were always rife in Egypt. It is thus not remarkable that out half of the 237 prescriptions contained in the Cairo papy- (c. 9th century A.D.) deal with these conditions. For the jority of the ophthalmic remedies there is no indication of the dition for which they were applied. There are, however, 13 cataract, 18 for dimness of vision, three each for abscesses and ammation, 13 for trachoma and two for amauroses. Among skin and scalp affections prescribed for are melanoderma, pes, itch and lichen. We read of remedies for abscesses, boils, es, cuts and bites, ulcers, gangrene sores and swellings. nmin ground with moistened rue is taken for three days for er. Opium, calf's fat and milk melted together and applied m cures earache with such rapidity that the physician is ised to collect his fee in advance! A mixture of red and yellow iol and alum is recommended for toothache. Two formulae the extraction of teeth are of interest, for though dental caries alveolàr abscesses have been found in mummies of the raonic period there is no evidence of the extraction of teeth hat early time. Considerable knowledge of and skill in sur- may be gathered from a Coptic surgical instrument case in Cairo Museum, the space allotted for knives and scalpels wing that operations were no simple affair.

Iesopotamian Medicine.—The civilisation of the valley of the hrates and the Tigris had reached an advanced degree of de-pment about 4,000 B.C. Babylonian medicine was purely irical. It occupied, however, a less important rôle in the art ealing than magic. The liver was regarded as the central n for the blood, the true life principle, which was divided into kinds, blood of the day and blood of the night. Disease was emon that entered the body and must be expelled. The rmacopoeia made use of mineral, vegetable and animal sub-ces. Among remedial agents were honey and syrup of dates, s, blood-letting, use of cups for drawing blood to the surface he body, cold shower and warm baths, clysters, various es, friction with oil. An ointment composed of plants cooked rease, or a decoction of copper-ore in beer, was used in cases phthalmia, a very common complaint in Mesopotamia also.

ssyrian Medicine.—The more northern Assyrian medicine the same foundations and followed the same methods as the hern Babylonian. Therapy was exorcism and incantation prophylaxis, although the accounts of surgical procedure in Code of Hammurabi imply an elementary knowledge of omy. We gather hints, however, from the medical texts the physicians of Nineveh may have been less ignorant has been supposed. Some 250 vegetable drugs and 120 min- drugs were known, as well as 180 derived from other uniden- sources, making a total of 550. The names of these drugs r many thousands of times in the medical texts. To the e must be added remedies consisting of various alcohols, oils, honey, wax and various kinds of milk. Among the es most frequently met with in the texts are: pine and fir entines, rose, cedar, darnel, marigold, heliotrope, asafoetida, arisk, liquidambar, storax, mustard, galbanum, henbane, , myrrh, arnoglosson, castor oil plant, mint, tragacanth, el, cypress, nightshade, millet, poppy, fig, laurel, pome-ate, wheat flour and mandrake. The mandrake seems to entered medical magic from Babylonian sources.

Persian Medicine.—Iranian medicine became laicised in Zoroaster's time when the "mages" were superseded by the physicians whose business was to restore health. It bears points of resemblance to ancient Hebrew medicine which may be dependent on it. Treatment of the sick consisted of incantations, vegetable drugs and the use of the knife. Hygiene was one of Zoroaster's main preoccupations: "A healthy man is a moral man."

Indian Medicine.—Hindu conceptions concerning the causes of disease were very confused. The confusion may be the result of the mixed origin of Indian pathology. The earlier Indian physicians utilised the senses of taste and smell as well as inspection, palpation and auscultation for purposes of diagnosis. Hygiene and diet played an important part in the life of the people. The pharmacopoeia of India is very rich, the great majority of drugs belonging to the vegetable kingdom. Charaka (pre-Buddhistic period) knew of 500 plants that possessed remedial virtues, Susruta mentions 760, of which cinnamon, pepper, cardamons, spices and sugar were native. He also gives lists of drugs classed according to their action into lists of cerebral sedatives, emetics, purgatives, anodynes, etc. Diabetes mellitus was first described by Indian physicians who noticed that flies and other insects were attracted to the urine of patients suffering from this malady.

In surgery the ancient Hindus were probably superior to any of their oriental neighbours. Susruta mentions eight kinds of surgical operations. Fourteen different kinds of surgical dressings were in use; cotton, woollen, linen and silk for bandages. Special splints of withes of bamboo were employed in cases of fracture and dislocation. These were later adopted in the British army as the "patent rattan cane splint." It is regrettable that it continues impossible to assign dates to ancient Indian medical documents with any degree of confidence.

Deteriorated Remains of Scientific Medicine.—It has become increasingly evident that the culture of many savage and semi-savage tribes is in fact little but decayed civilisation. This is particularly true in the department of medicine. Researches, for instance, on Anglo-Saxon medicine have shown it to be little but the system of the classical peoples corrupted, deteriorated and misunderstood. In view of this "derivative" character of much so-called "primitive" medicine, a reinvestigation of the medical customs of savage peoples is demanded.

Stanton Roberts, *Llysieulyfr Meddyginiaethol a briodolir i William Salesbury* (*A Herbal attributed to William Salesbury*) (1916), Charles Singer, *Early English Magic and Medicine* (1920), and "The Lorica of Gildas the Briton (?547)," *Proc. Royal Society of Medicine* (*Historical Section*), vol. 12, p. 124 (1920), and Herbert Schöffler, *Beiträge zur Mittelenglischen Medizinliteratur* (Halle 1919). F. Ohrt, *Danmarks Trylleformler* (Copenhagen 1917), texts in Friedrich Wilhelm's *Denkmäler Deutscher Prosa des 11. und 12. Jahrhunderts* (Munich 1914 and following years) and articles scattered through the pages of Johannes Hoops, *Reallexikon der Germanischen Altertumskunde* (Strassburg 1911–9) and the international Dutch journal *Janus.* The surviving Gaelic MSS. contain a surprising proportion of medical texts. By the publication of the catalogues of these MSS. in the Advocates Library at Edinburgh (1912), in the Libraries of Trinity College, Dublin (1926), and in the British Museum (1926), a new source of Folk Medicine has been tapped. (C. Si.)

MEDINA (*see* 18.64).—Before the World War, Medina was less known to Europeans than Mecca, although it was described by the earlier travellers, Burckhardt and Burton, and by Wavell, who visited it in 1908. Before the World War the normal resident population was estimated at 40,000, of whom a large proportion were aliens who had settled after pilgrimage. The Turks deported about three-quarters of the inhabitants during the blockade, and, allowing for further decrease by disease, the population in 1920 was well under 10,000. Much new information regarding existing conditions in the city was obtained as a result of the War operations. The dimensions of the city were overestimated by earlier writers, the walls actually measuring not more than 1½ m. in circumference, with the longest diameter a little over ½ m. east and west. The Hejāz railway has its terminal station outside the city walls at the Bab el 'Ambari, the gate on the southwest through which runs the road to Yenbo'. There are normally three trains weekly from Damascus, and the journey takes 5½ days. During the War a branch was carried from the main line, through a breach in the walls on the northwest side, to the outskirts of the *Haram* or Great Mosque, which was used as a munition store and was intended to serve as an inner citadel in case of siege.

At the outbreak of the revolt in June 1916 the Arabs, unable to take the city by assault, withdrew and began a blockade, which —as they were unwilling to bombard the city for fear of damage to the holy places and refused to cut the water supply conduit— lasted until the Turks surrendered the city in Jan. 1919. In 1917 Fakhri Pasha, commander of the garrison, devised a scheme for the rebuilding and modernisation of Medina, but all that happened was the destruction of a great number of houses for the sake of the beams and woodwork to feed the railway locomotives. Extensive palm plantations outside the walls, east and northeast, were also ravaged for the same purpose. Large palm gardens which formerly occupied much space within the wa were in great part built over, and the Barrel Manakha, or cent open space, was encroached upon. Sherif Ali, son of King H sein, became emir of Medina in 1925. In the later part of th year the city was invested by Wahhabi troops.

MEDITERRANEAN SEA (*see* 18.67).—In 1910 the lands wh bound the southern and eastern parts of the Eastern basin the Mediterranean were under real or nominal Turkish contr In theory, that is to say, the Sultan of Turkey was suzerain the area extending from the frontier of French Tunisia, that from the Gulf of Gabes, to the Gulf of Alexandretta, and own also the island of Cyprus. At the present time Tripoli, whi abuts on Tunisia, is Italian; Egypt forms an independent ki dom; the mandated territories of Palestine and Syria are attach to Britain and France respectively, and Cyprus has been nexed to Britain. From the whole of this long stretch, therefo the Turk is now excluded.

Political Changes.—In the northern part of the Eastern ba and in its connected subsidiary seas, conditions were more co plicated. The whole of Asia Minor was and remained politica Turkish: from the ethnic and economic standpoint indeed was more definitely Turkish in 1926 than it was in 1910. the changes in the European littoral of the Aegean Sea w great. In 1910 Greece was but a small state, though at the sa time Greeks were widely distributed around all the shores of Aegean and within the adjacent lands and had great econor influence there. Crete was still Turkish, as was the whole Thrace, together with the region vaguely called Macedon this meant that politically the Aegean was chiefly a Turk sea. In 1926 Crete was Greek, and Turkey had also lost whole of Macedonia and all but an eastern fragment of Thra In other words, Greece in 1926 included almost the whole the European littoral of the Aegean, and to her previou existing ports had been added that of Salonika, which had quired great significance. The interchange of populations tween Greece and Turkey in 1923–4 meant further that acquired area was in process of becoming ethnically more Gr than it had been in the past. On the other hand, Greek influe in western Asia Minor disappeared, and with it the port Smyrna lost much of its former trade.

The changes on the Adriatic littoral and on the adjacent pa of the Ionian Sea had been great. In 1910 Turkey held in Epirus area a frontage on the Ionian Sea and had also a w window on the Adriatic. The extension of Greece to the no and the establishment of the independent State of Albania, w territorial changes which preceded the outbreak of the Wo War; but that War resulted in others of even greater importan Prior to its outbreak, Austria-Hungary, which had anne Bosnia-Herzegovina from Turkey in 1908, held the eastern co of the Adriatic, from the edge of the very narrow strip wh was Montenegrin to beyond the Isonzo. The Peace Trea gave the greater part of the littoral to the Serb-Croat-Slov State, and the smaller part to Italy, and left a cause of disc between the two in regard to the fate of the port of Fiumè.

In the Western basin, save for agreements in the case Morocco, there were no territorial changes: a certain amount political equilibrium had been reached there long prior to period under consideration. On the other hand, the new posit within continental Europe generally brought about by the lead to fresh developments within the Mediterranean zo France, Italy and, to a minor extent, Spain made definite tempts to develop their trans-Mediterranean possessions, and establish themselves more firmly on the shores of that sea.

Since Spanish action was limited to a coastal belt in Moroc it may be briefly dismissed. In 1912, the year in which French protectorate was accepted by the Sultan of Moroc France and Spain reached an agreement as to the limits of th respective zones within that country. Spanish attempts to ma occupation effective in their own zone were probably influen primarily by the French advance: other influences were the of the remnants of the former colonial empire of Spain and continuous emigration to Algeria, which had acquired a la

anish element in its population. The convention of 1923 be-
een Great Britain, Spain and France in regard to Tangier,
en placed under a régime of permanent neutrality, indicated
growing importance of France in the Western basin of the
editerranean. The refusal of Italy to recognise the agreement,
the ground that she was not represented at the convention
s similarly an indication that that State, now freed from
xiety as regards her northeastern frontier, was directing her
icy more and more definitely towards Mediterranean affairs.
French Policy in the West.—If the developments in Morocco
re the chief events in the West since 1910, yet other signs were
wanting of the new orientation of French policy there. As
ntrasted with Italy and even with Spain, there is in France no
rplus population seeking new lands for settlement. Thus the
t that the North African territories, particularly Algeria,
e opportunities for European colonisation is not of much
ect importance to that country. On the other hand, there is
at need of man-power, particularly for the army. Though the
ritories of the Mediterranean littoral are not densely peopled,
y do form a recruiting ground, and Algeria, Tunisia and Mo-
co all furnish divisions to the French Army. But these lands
but the margin of a vast area which, interrupted politically
y by smaller *enclaves*, and physically by the Sahara desert,
w extends to the Gulf of Guinea and, further eastward, to far
yond the equator. Parts of this area contain a virile coloured
pulation, whose members make good soldiers. In this con-
ction it may be noted that Senegalese regiments have formed
art of the French Army since 1911, and that in 1919 the na-
e element in the army was greatly increased.

The bearing of these facts is twofold. In the first place it is
ential that facilities for transverse traffic between the French
the North African coast opposite should exist in peace, and
t so far as possible the safety of the routes should be assured
time of war. Secondly, schemes are in contemplation for
rcoming the obstacle presented by the Sahara, in such a way
to ensure easy land communication between the littoral
ssessions and those further south, in order that the two may
velop in combination. A railway connecting French West
ica directly to the Mediterranean coast would have great
ategic importance in time of war, while the feasibility of
tor communication had already been demonstrated. These
ssibilities increase the significance of the Mediterranean ports.
erta, Algiers and Oran are already important naval stations
submarine bases, and the French are making great efforts
develop and strengthen all the ports on this littoral, as centres
trans-Mediterranean traffic. This emphasis on cross-routes
ot only significant in itself, but is something entirely modern.
New Rôle of the Mediterranean.—Previously, as is well shown
the long-drawn-out row of British stations at Gibraltar,
lta and Aden, the Mediterranean was primarily of impor-
ce as a longitudinal thoroughfare. Up till the post-War
riod, between Malta and Aden, there was in Egypt a country
der British influence. With the establishment of an inde-
dent kingdom there, and the changes just noted, it is obvious
h that Great Britain's position in the Mediterranean has been
akened, and that a new set of traffic routes is being super-
posed on the old. It may be added that if, as is sometimes
ted, French withdrawal from Egypt in 1883 was due to the
r of renewed attack on the northeastern frontier of France,
en French acceptance of the mandate in Syria is an indication
t this reluctance to extend her extraterritorial commitments
s ceased to exist under the new conditions.

Italian policy in the Mediterranean area since the War had
en influenced by somewhat different motives. Italy has a
adily increasing population and the emigration laws in the
ited States tended to restrict one of the pre-War outlets for
surplus. Thus Italian policy was directed towards attempts
promote home industry and commerce in order to attract a
rt of the dense rural population from the land, and also to find
w areas of possible settlement. The latter motive led to
orts to develop Tripoli, obtained from Turkey in 1912, while
former affected Italian policy in the eastern part of the
Adriatic. By the acquisition of the peninsula of Istria, with the ports of Trieste, Pola and Fiume, and of Zara and the island of Lagosta, Italy obtained both complete protection for the eastern coast of the peninsula and opened up possibilities of notable commercial developments. The Italian advance meant that Austria and Hungary lost all outlets on the Adriatic, and thus had no direct access to the Mediterranean Sea.

The collapse of the former Ottoman empire resulted in the rise in the eastern Mediterranean of states which were either actually new, as are the Kingdom of Egypt, Yugoslavia and the much smaller State of Albania, or, as in the case of Turkey and Greece had undergone such radical modification—territorial, political and ethnical—as to be to all intents and purposes new. Such states were for the most part characterised by a strongly nationalistic spirit which retarded economic recovery from the effects of the War. The result was that the chief ports at first showed decay rather than advance. This was particularly true of Constantinople and Smyrna, and even Salonika, where the Yugoslav state had had a free zone since 1923, did not make notable progress. Despite their long Adriatic littoral also, the Yugoslavs were not able to develop an adequate outlet there. By an agreement reached with Italy in 1924 the port of Fiume became Italian and the adjacent one of Port Baross, Yugoslav. The friendly adjustment of this difficult question is probably an indication of future closer economic connection between the two Powers.

This summary account of conditions up to 1925 makes it clear that political developments, especially in the southern and eastern parts of the Mediterranean area, took place between 1910–25 with a rapidity all the more startling in view of the long antecedent period of complete or partial stagnation. But the apparent suddenness of the political and territorial changes was due to the fact that they were the consequences of cumulative economic changes which had been going on for a long period of time. In particular, the increased production of cereals for export in central and eastern Europe, and the discovery and working of oil-fields alike along the Carpathian border and in the Caspian region, gave to outlets to the eastern Mediterranean an importance which they did not possess in earlier times, and made readjustments inevitable. The Mediterranean Sea was no longer what the opening of the Suez Canal and the associated growth of European influence in the Far East had made it—primarily a thoroughfare for world commerce. It was becoming also an important outlet for the developing lands round its southern and eastern shores.

Present strategic conditions in the Mediterranean region are discussed in D. H. Cole's *Imperial Military Geography* (London, 1925). See also M. I. Newbigin, *Geographical Aspects of Balkan Problems* (London, 1915); I. Bowman, *The New World: Problems in Political Geography* (London, 1925). (M. N.)

MEHTA, SIR PHEROZESHAH MERWANJI (1845–1915), Indian municipal reformer, was the son of a Bombay merchant. Educated at the Elphinstone College, he was the first Parsee M.A. of Bombay University and coming to London to read at Lincoln's Inn was also the first Parsee to be called to the English Bar (1868). With Dadabhai Naoroji he founded the organisation which grew into the East India Association. Returning to Bombay he rapidly made a name as an advocate. Appointed in 1869 as Justice of the Peace, he served on the new Bombay Corporation from 1872 till his death. He also served for over 30 years on the Bombay legislature. For the last few months of his life he was vice-chancellor of Bombay University. Created a C.I.E. in 1894, he was advanced to the knighthood of the order 10 years later. He died in Bombay Nov. 5 1915.

See the political biography by H. P. Mody, *Sir Pherozeshah Mehta*, 2 vol. (1921). Much light is thrown on Mehta's services to his native city in *Rise and Growth of Bombay Municipal Government* (1913), by his most intimate co-worker, Sir Dinshah Edalji Wacha.

MEIEROVICS, ZIGFRIDS (1887–1925), Latvian statesman, was born Jan. 24 1887, the son of a country doctor in Courland, and was educated at the Riga Polytechnic. He first worked in an insurance company and afterwards in an agrarian bank.

This training gave him an insight into financial problems and prepared him for the prominent part he was to play in the stabilisation of Latvian currency. In Nov. 1918 he became the first foreign minister of independent Latvia and, as delegate to the Peace Conference, he secured Latvia's recognition and later succeeded in gaining her admission to the League of Nations. From 1918 until his death he held office almost continuously as foreign minister and was once prime minister. He was killed in a motor accident on Aug. 22 1925.

Shortly after this date a well-known student of the movement for independence in the Baltic States expressed the opinion that of all the leaders of that movement in the various states involved, Zigfrids Meierovics was at once the most statesmanlike and the most influential. He was a man gifted with an unusual power of looking ahead; and he was able to recognise the real problems facing the Baltic States in the years immediately following the World War with probably greater facility and clarity than any of his colleagues in leadership. One of the foundations of his foreign policy was the conviction that Estonia, Latvia and Lithuania possessed many interests in common and should therefore endeavour to co-operate for the common good of all three states. The confidence which he inspired in his own countrymen is abundantly proved by the insistence with which the latter kept him in office from 1918 onwards.

MEIGHEN, ARTHUR (1874–   ), Canadian statesman, was born at Anderson, in the county of Perth, Ontario, June 16 1874, the son of Joseph and Mary Meighen. He was educated at St. Mary's Collegiate Institute and at Toronto University, and became a barrister-at-law. He married in 1904 Jessie Isabel Cox, daughter of the late Charles Cox of Granby, Quebec. His political career began in 1908 when he was elected to the House of Commons as the Conservative member for Portage la Prairie in the province of Manitoba. His talent as a debater was at once recognised. In 1913 he became solicitor-general in the Government of Sir Robert Borden; and in Oct. 1917 secretary of state and minister of mines. Later he became minister of the interior. In 1918 he accompanied the Canadian Prime Minister to England to attend the Imperial Conference, and on Sir Robert Borden's retirement Mr. Meighen became Prime Minister and secretary of state for external affairs on July 10 1920. In June 1921 he attended the conference of prime ministers in London, where his representations were said to have had a notable effect upon the political groups in Canada. Mr. Meighen held the office of Prime Minister until the general elections in 1921, when the Conservative party was defeated; he then became the leader of the Opposition, and for four years was a vigourous opponent of the Liberal Government. He supported the disarmament resolution introduced by the Prime Minister, Mr. Mackenzie King.

The Military Service Act, under which conscription was enforced in 1917, was largely, in so far as its legal preparation was concerned, the work of Mr. Meighen, and the vigour with which he supported it in Parliament drew upon him the hostility of all those opposed to that measure. As the sentiment against conscription was especially strong in Quebec, the feeling against him in that province was intense, and prevented the policy of his party from receiving the due consideration of the electors. Mr. Meighen consistently repelled the personal attacks made upon him as the enemy of the French Canadians, but without much success. In the elections of 1925 the Conservatives, under the leadership of Mr. Meighen, were overwhelmingly victorious in Ontario and the maritime provinces, but with a practically solid Quebec against him it was impossible to obtain a majority, and the Government remained in the hands of the Liberals. In June 1926, on the resignation of Mr. Mackenzie King, Mr. Meighen took office as Premier, but his government was immediately defeated and a general election took place.

The adoption by the United States of protection, as well as the great industrial development of that country, placed Canada, in Mr. Meighen's view, at a disadvantage. He therefore strongly advocated protection for his own country, in order to prevent the United States from capturing the home markets. He was c vinced also of the necessity for preserving the natural resour of Canada, particularly the almost unlimited water power envied by the bordering states, as well as the products of forests. He resisted all attempts made by the United States secure for their territories electrical power generated from wat courses in Canada. Mr. Meighen made constant efforts bring about a fusion of the diverse elements in the Canad population. He was made a member of the Imperial pri council in Oct. 1920. (A. G. D.)

MELBOURNE, Victoria (*see* 18.90), the temporary seat the Federal Govt. and the capital of Victoria, Australia, w a population of 816,800 (852,850 including suburbs), conta more than half the population of the whole State, and grown with great rapidity. The formation of a Greater Melbou council was decided upon in 1925. The city has been much i proved in appearance by the planting of trees on the banks the river and in the chief streets. There were 71½ m. of elect tramways in 1923, and the suburban railways have be electrified. In 1916 a mint for silver and bronze coins established here. In 1924 it was decided to build a large tem in a commanding position in the city as an Australian W Memorial. In 1917 a Commonwealth Shipping Board, with interstate headquarters at Melbourne, was set up to deal wi all questions concerning shipping, but it was not altogether success. Melbourne has a large trade, and 35% of the total w export of Australia is dealt with in sales. Large sums have be spent on dredging and reclamation of land in the river and ba

MÉLINE, FÉLIX JULES (1838–1925), French statesman (18.94), died in Paris Dec. 21 1925.

MELLON, ANDREW WILLIAM (1855–   ), American bank and public official, was born in Pittsburgh, Pa., March 24 18 After graduating from the University of Pittsburgh, he enter the banking house of Thomas Mellon and Sons, and later beca a partner. The business developed into three large institutio the Mellon National Bank, the Union Trust Company and t Union Savings Bank, all of Pittsburgh. Mr. Mellon was elect president of the first mentioned in 1902, and was vice-preside of the other two. He was interested in the development of t coal, coke and iron industry of Western Pennsylvania and w often associated in various enterprises with Henry C. Frick. founded the town of Donora, Pa., and established a large ste mill there. Another of his enterprises was to promote the bui ing of the first independent pipe-line, in competition with t Standard Oil Co., through Pennsylvania. He was a director numerous corporations, and was a conservative Republica opposing the League of Nations. In 1921 he was appointe Secretary of the Treasury in the Cabinet of President Hardin and continued to hold this office under President Coolidge. H was chairman of the Pennsylvania delegation to the Republica National Convention held at Cleveland, O., June 10 1924.

As chairman *ex-officio* of the World War Foreign Debt Con mission Mr. Mellon had a large share in formulating the polic of the United States in regard to funding the war debts of foreig governments owed to the U.S. Government. He stressed th importance of debtor nations preserving the sanctity of the respective obligations but laid down that no nation can be aske to pay to another government sums in excess of its capacity and further, that no settlement which is oppressive and retard the recovery and development of the foreign debtor is to the bes interests of the United States or of Europe. In this spirit h conducted negotiations with the various European debtor State which resulted in funding agreements being arrived at wit Belgium, Czechoslovakia, Estonia, Finland, Great Britain Hungary, Italy, Latvia, Lithuania and Poland. The principa obligations funded under these various agreements amounted t $6,383,411,669, in addition to accrued interest, $1,006,502,331

In the management of the large internal debt of the U.S Govt. resulting from the World War, Mr. Mellon was equally successful. He laid down and rigidly adhered to a policy o providing for debt redemption annually out of current revenues As the floating debts and the Liberty Loans fell due they were i ırt paid off, in part refunded, at a lower rate of interest. As a sult the U.S. national debt fell from $24,330,889,731 in 1920 to 20,298,358,156 in 1925. Mr. Mellon was a strong advocate also tax reduction, especially in the case of the surtax rates on comes, maintaining that these should not exceed a maximum 20% and that such reduction would be a great aid to general isiness and promote widespread prosperity. Under Mr. ellon's prompting, Congress gradually lowered the income x rate until in 1926 the surtax was reduced to 20%, yet without ıy corresponding fall in the amount of tax receipts. Mr. ellon, who has written for this *Encyclopdæia*, is the author of *axation: The People's Business* (1924).

MEMEL (*see* 18.104), a port on the Baltic coast at the mouth the river Memel or Niemen, with an economic hinterland tending across Lithuania into Poland and Soviet Russia, the incipal export being timber floated down the waterway. ɔlitically, Memel is now an autonomous district of Lithuania. ıe population of the town, approximately 25,000, is almost tirely German, and has been so since the 13th century, when emel, like Riga and Revel, was founded as a German trading ation.

Before the World War the town of Memel, with a strip of rritory east of the river, belonged to Germany, while the nterland belonged to the Russian Empire. Under the Verilles Treaty (Article 99), Germany ceded all her territory east the river to the Allied and Associated Powers and undertook accept whatever disposal they made of it. Upon the ratificaon of the Treaty the Allies occupied the territory and took er the administration. This provisional régime lasted three ars, owing to the dispute between the two new states of thuania and Poland over Vilna (Wilno) (*q.v.*), and the conseent delay in the official recognition of the Lithuanian Governent. The Conference of Ambassadors did not take up the question Memel till the autumn of 1922, and meanwhile it had been ggested that Memel might be given a status in regard to thuania like that which had been given to Danzig in regard to land. This was unacceptable to the Lithuanians, since the pulation of the country districts of Memel territory was thuanian in nationality, while the port was almost the only ssible maritime outlet and inlet for Lithuania herself. Accordgly the Lithuanians, imitating the conduct of the Poles at lna, seized Memel by a surprise attack on Jan. 15 1923, and rced the French garrison to surrender and evacuate.

On Feb. 16 the Conference of Ambassadors proposed that the lies should transfer the sovereignty over the territory to thuania, subject to local autonomy and to freedom of transit Poland. In the working out of the details so many difficulties re raised by both Poland and Lithuania that in Sept. 1923 the se was referred to the League of Nations. The council appoint- a commission of enquiry under the chairmanship of an nerican citizen, Mr. Norman Davis, and the proposed conntion for giving Memel autonomy within Lithuania with edom of transit for Poland, as revised by the Davis Comssion, was eventually accepted by all parties, and signed in ay 1924. In March 1924 the commission presented a draft nvention to the Council. This Convention constituted the emel territory as a unit within the sovereignty of Lithuania h a clearly defined measure of administrative and financial tonomy and with a governor to be appointed by the Presiıt of the Lithuanian Republic. The port was defined as a rt of international concern to which the provisions of the ague's Barcelona transit conference apply, and was placed der a harbour board including a technical expert of neutral tionality appointed by the League.

MEMORIALS: *see* ARCHITECTURE; SCULPTURE.

MEMPHIS, Tenn., U.S.A. (*see* 18.107), developed into a disbuting centre covering the entire South after the reopening the Mississippi river transport by the establishment of the Federal Barge Line in 1918. The population in 1910 was 131,105; in 1920, 162,351, of whom 61,181 were negroes and 5,844 foreign-born; and in 1925, 174,533, this being the census bureau estimate. Annexations in 1919 (4·6 sq. m.) and 1925 (1·2 sq. m.) brought the city area up to 26·5 square miles. The output of factories within the city limits was valued at $30,242,000 in 1909; $117,718,000 in 1919; $95,537,305 in 1923. By 1925 there were 900 industrial plants in or near Memphis, with an output estimated at $200,000,000. The greatest industrial development during the period from 1910 has been in hardwood products, cotton-seed products, heavy bags, steel and iron and automobiles, including an assembly plant of the Ford Motor Co., established in 1924, with a daily capacity of 350 cars.

Noteworthy improvements include the municipal rail and water terminal (1913); the Harahan bridge (1917); the Union Belt Railway; a new water pumping station (1923–5), multiplying by four the potential supply; a municipal auditorium seating 12,000 (1924); and the improvement and expansion of the electric service. Hydroelectric power will be available from the Muscle Shoals district of Alabama and the White river project in Arkansas. A city planning commission, created in 1921, secured the preparation of a comprehensive plan and the adoption of zoning ordinances. The cost of living in Memphis is high. The West Tennessee State Teachers College was established at Memphis in 1912. In Sept. 1925 Southwestern College, a Presbyterian institution, founded in 1875, moved from Clarksville to Memphis.

MENCKEN, HENRY LOUIS (1880–), American critic, was born at Baltimore, Md., Sept. 12 1880. He attended the Baltimore Polytechnic Institute, and in 1899 became a reporter on the Baltimore *Morning Herald*. He left that paper as editor in 1906, and joined the staff of the Baltimore *Sun*, to which he continued to be attached while engaged in many additional literary activities. In 1908 he became literary critic for *The Smart Set*, and was also joint editor 1908–23. In 1921 he became contributing editor of *The Nation*, and in 1924 was one of the two founders of *The American Mercury*, of which he became sole editor in 1925. He is a satirist rather than a critic, and represents the viewpoint of the extreme anti-academic element in the literary world. Among his numerous publications are *George Bernard Shaw: His Plays* (1905); *The Philosophy of Friedrich Nietzsche* (1908); *A Book of Burlesques* (1916); *Damn; a Book of Calumny* (1917); *A Book of Prefaces* (1918); *The American Language* (1918); *In Defence of Women* (1918); *Prejudices* (five series, 1919–26); and *Americana* (1925). He has also written critical prefaces to the works of Brieux, Swift, Stephen Crane, Cabell, Nietzsche, Ibsen and Wilde. (*See* AMERICAN LITERATURE.)

MENDELISM (*see* 18.115).—The progress in physiological science made possible by Mendelian methods is described in the articles GENETICS and SEX. In the present article the influence of those discoveries on the development of biological thought and their application to the practice of breeding are considered.

Analysis.—Modern genetics introduces into biology a factorial or analytical conception of organisms, which are now recognised as largely possessing attributes behaving as units, and as such capable of being detached and transferred to any other type with which cross-breeding can be effected. The limits governing this principle of segregation and recombination are still undetermined.

Phenotype and Genotype.—In former considerations of biological problems no account was taken of the consequences of the fact that each of the higher organisms is, in modern language, *diploid*, that is to say, a double structure containing factorial contributions derived respectively from the *haploid* or simple male and female cells which in fertilisation united to produce it. Since some of these factors inhibit the effect of others, and since some give no sign of their presence in the organism unless other complementary elements are also present, the appearance of an organism is an imperfect guide to its genetic potentialities. We have thus to distinguish the organism as it outwardly appears to be from that which it actually is by genetic composition, a distinction which Johannsen has conveniently expressed by the use of the terms *phenotype* for the former and *genotype* for the latter. Systematic or classificatory works, both zoological and botanical, abound with errors arising from want of appreciation of this fundamental distinction, which must constantly be remembered, especially, for instance, whenever the significance of varietal or intermediate forms has to be estimated.

Variability.—Evidence formerly regarded as proof of abundant contemporary variability in the species of animals and plants must be submitted to searching tests before it can be so accepted. Observations of variability once deemed adequate are now seen to be capable of quite different constructions. Proof that an observed departure from type is a contemporary genetic variation can only be obtained in exceptional cases which have been critically observed under experimental conditions. Putative variation is commonly nothing but the recurrence of a recessive form, or the emergence of some other segregant, from a stock genetically impure; more often still the direct product of a cross. The existence, therefore, of a multitude of varietal forms, so far from simply providing a convenient basis upon which a theory of the evolution of species can be erected, becomes itself an antecedent problem; and instead of asking, as they used to do, how the species have been built up out of the varieties, biologists are rather concerned to discover whence and by what process these variations have come to exist. The belief that substantial genetic change commonly accrues by summation of impalpable differences has been generally abandoned as devoid of evidential foundation. Such differences are mostly fluctuational, largely dependent on circumstance rather than on genetical units and hence not transmissible. Summation, when a genuine phenomenon, is a consequence of purification or the attainment of homozygosis. The idea that a characteristic could in any other way increase as a result of selection is out of place in an exact or even a logical science.

Variation by Loss and by Addition.—Whether the evidences of authentic variation remaining after the deduction of spurious testimony has been made, suffice as a basis of evolutionary theory has been questioned by competent naturalists. Lotsy, for example, maintains that we have no proof of contemporary variation arising otherwise than as a consequence of crossing; and apart from such extreme announcements it is noticeable that as regards varieties of animals and plants anciently domesticated, modern authorities usually incline to ascribe a multiple origin even for forms like wheat, the fowls, pigeons, sheep, horses, etc., which used formerly to pass for derivatives from single types, a belief now felt to be inconsistent with what is known of the limits of variability. Distinction must be made between recessive and dominant variations, arising respectively by loss and by addition. As regards recessive variations arising by loss of elements few will doubt the adequacy of the records (*e.g.*, in the sweet pea, *Primula sinensis*, etc.). As regards the *de novo* appearance of dominant characters the evidence is less abundant. Morgan and the American geneticists have made prominent several instances of this kind in Drosophila (fruit fly), of which the spontaneous origin of " eosin " (a new and peculiar pink) eyes in a white-eyed strain may be cited. Admitting provisionally these examples as free from objection they are, nevertheless, extraordinary events and not common occurrences. Were the dominant in question one already familiar we should hesitate to believe in its spontaneous origin. That a pea genetically wrinkled, having the characteristic starch of the wrinkled varieties, should without crossing produce a variety with " round " starch-grains would in modern lights appear not much less improbable than the spontaneous generation of life.

With plausibility a number of human malformations, such as praesenile cataract, claw foot-and-hand, etc., which have been regarded as descending as dominants, may be interpreted on these lines as in reality due to loss. From almost the beginning of Mendelian studies surprise has been felt that so many curious abnormalities in man, of which at least some 30 may be enumerated, should behave as dominants, seeing that novel characters most frequently are demonstrably recessive. Inasmuch as these " dominants " are so abundant in man, though otherwise rare, something no doubt remains to be explained; but we may avo the difficulty of interpreting them all as factorial additions, f with equal probability the normal may be represented as po sessing an element which, when homozygous, maintains develo ment in its proper and normal course. Mohr and Wriedt, di cussing the inheritance of a new type of shortened digits, recent made the suggestion that we have here to do with a charact which, in the homozygous state, is *lethal*. In other words, if o element of " normality " only be present the individual exhibi the peculiarity, but if both elements of normality are wanti the consequent malformation is so extensive that the embr perishes at some early stage of development. The normal el ment would then be recognised as the positive contribution, a in the absence of at least one such contribution the embryo non-viable. Some slight evidence is already adduced in suppo of this view; and since lethal contributions certainly play a gre part in genetical histories, we should be prepared for a wide a plication of this principle, especially to the descent of deformit

But, as explained in the article GENETICS, nothing absolute forbids us from inverting the representation of positive and neg tive factors by extension of the conception of inhibitors, of whi many are familiarly known; so that we may express the appare addition of a new element as a loss of one which when prese had repressed the new attribute. This symbolism, though a mittedly objectionable when dominance is complete, does wit out strain apply to all cases in which the heterozygote is inte mediate, and a large range of alleged new dominants can covered. In so far as this conception applies, evolution is co ceived of as a process of unpacking, a progress consisting in t loss of component elements.

Mutation.—The term *mutation* introduced by de Vries, is no generally accepted to denote definite genetical variations whi are sensibly discontinuous. Though contemporary exampl which satisfy all tests are not abundant, there is no question th they occur and have occurred in most of the forms of life. The are indeed part of the occasional experience of most breeders animals and plants. The special example, the Oenotheras, which de Vries mainly founded his own theory, was singular unfortunate and must, as explained in the article GENETICS, now discarded as inapplicable. Mendelian analysis was on lately made known, and the group of discoveries comprised the term genetics were in an incipient stage; nor had the criter of genetic purity, which must be applied to a parental for before the production of new types from it can be accepted proof of original mutation, been clearly established. The Oen theras which produce the presumed mutations are now prove to be no pure genotypes, and the suggestion that they were in " period of mutation " arose from a misunderstanding of th nature and consequences of heterozygosis.

Inter-specific Sterility.—The new forms whose productions w witness are never new species. In *Primula sinensis* about pairs of factorial differences have been determined, which their several combinations present an amazing polymorphism A systematist, if he met these forms in nature, might and pro ably would quite justifiably take many of them for distin species. But interbred, they and their products are perfect fertile. Polymorphism like this is, even in a state of nature, f more abundant and far greater than the evolutionists of the la century imagined, yet it avails us little as material out of whi true specific differences can be supposed to develop. Th conspicuous defect in the evidence for the origin of species common descent remains. Though much is known as to the inc dence of variation, not rarely of a magnitude which might nat rally be claimed as constituting specific difference, no one h yet raised types from a common origin which when interbre produce sterility of the kind and degree forming one of the co monest attributes of crosses between natural species. By wha ever concatenation of arguments theories of evolution have be constructed, the most essential link has never been supplie The lapse of time is occasionally invoked in the hope of rectifyi this and similar evidential defects, a strain which has been mai tained distinct for a long period being thought more likely to sho

SIMPLE COLOUR INHERITANCE IN THE SEEDS OF THE COMMON GARDEN PEA

When yellow-seeded and green-seeded peas are crossed, all the second generation has yellow seeds, but in the third generation three-fourths of the seeds are yellow, one-fourth green. In the second generation the green is latent, or recessive, being overshadowed by the dominant yellow. If plants from the green seeds of the third generation are crossed green seeds always result. The apparently similar yellow seeds may be pure yellow or hybrid (part yellow, part green). If yellow-seeded plants from any generation are crossed, one-third will breed pure yellow, and two-thirds will breed hybrid yellow, giving in the next generation three yellow to one green.

HOW THE OCCURRENCE OF A NEW SPORT VARIATION MAKES POSSIBLE THE MULTIPLICATION OF EXISTING VARIETIES

In 1911 a yellow rat (a previously unknown variety) was caught in England. It was mated with black-hooded individuals, a recognised tame race which breeds true. The offspring were all brownish-grey like wild rats, but the grandchildren exhibited eight different varieties.

As the crossing of a constant strain with a variant from another and perhaps variable strain gives so many varietes of offspring, it is readily seen that where both the strains crossed already differ in many minor characteristics, there will be (as is observed in actual life) an almost infinite number of small variations from individual to individual.

interracial sterility when crossed with its progenitor than one newly separated. Reasoning of this kind, plausible enough in scholastic days, is not acceptable in an age of chemistry, nor may we suppose that that which is never begun will be attained by mere efluxion of time. The more genetical experience extends, the more serious does this hiatus in the evidence become.

Evolution.—In allusion to this and other difficulties, which genetic research has forced into prominence, the question is sometimes asked whether the theory of evolution holds its place so firmly as it did, or, more crudely put, whether Mendelian discovery has not "upset Darwinism." It should therefore be stated explicitly that in spite of all the objections with which the doctrine of the origin of species by descent is now seen to be beset—objections of which the strength is far more clearly known than before—and though as to the manner by which new species have come into existence geneticists adopt for the most part an agnostic attitude, yet all agree that the lines of argument converging to support the theory of common origin are so forcible and so many that no alternative can be entertained.

The geological record is conclusive.

The following may be taken as a cogent instance of this: if Angiosperms had existed in the carboniferous age their remains must have been preserved; therefore Angiosperms have arisen since that time, and we cannot conceive whence they came if not by descent from the pre-existing plants. Common descent, though rarely if ever a proposition demonstrable in any detail, ranks as an axiom. For Darwin and any other evolutionist before or after him this is a concession of the main claim. Parts of the apparatus by which the validity of that claim was enhanced have fallen into desuetude. In particular the modern geneticist assigns to *natural selection* a subordinate and inconsiderable rôle. Organisms are to be considered as co-ordinated systems. That each particular structure or instinct comprised in the system, which shows permanence or definiteness makes a contribution to the success of the system equivalent to the cost of its production is recognised as a fallacy. We are also reluctant to apply to the interrelations of the collective properties of organisms arguments which would be out of place in similar considerations of the attributes of unorganised substances. We no more look for utility in the details of a peacock's feather than in the iridescence of a Roman bottle or in the regularity of basaltic prisms.

Adaptation.—It is not merely in regard to the mode by which species have arisen that agnosticism has prevailed. While unwilling to accept adaptation, with Darwin, as a summation of happy accidents, we have no alternative to offer, nor is there in the attempts of various experimenters to find that organisms transmit to their posterity structural emendations in response to parental experience anything which sensibly alleviates the difficulty. Most of these claims are obviously faulty and few require serious notice.

Each step in the progress of this branch of science has rather compelled the recognition of genetic determinism; and the hope that by change in the conditions of life or by any external influences significant alteration can be induced in succeeding generations, whether of organisms amenable to experiment or of the human population, must be abandoned.

Classification.—The full implications of factorial analysis in relation to biological classification are not yet appreciated. The fundamental idea of the systematist, that animals and plants can be grouped into species, and that the distinctions between species are of a different order from those characteristic of varieties, is now scarcely open to question. Nevertheless, the belief held very widely by systematists, that certain classes of differences are important as being more fixed, and others trivial as being more liable to variation, is scarcely consistent with genetical knowledge. The frequency and amplitude of variation and the perfection of segregation must be empirically determined for the various organisms and for the various characters. No general rules can be predicated. Anthropologists, for example, are accustomed to regard special features of anatomy as comparatively sure guides to racial origin (*see* RACES OF MANKIND). Knowing what we now do of segregation and recombination we suspect that no characteristic is incapable of segregation and so of transference to another race: given the possibility of cross-breeding, the shape of the skull or other bodily peculiarity may be transferred in its entirety to individuals descending through another parent from a different race, and hence to a resulting population, more slowly but not less completely than a language or a custom.

The classificatory dichotomies in common use in the systematic arrangement of animals and plants have no prerogative significance except for mnemonic or demonstrative purposes; the number of the dichotomies is merely an enumeration of the pairs of factorial differences; and the order in which they are taken into account, though often treated as a matter of cardinal importance, is purely arbitrary. Peas, for instance, are divided first into tall varieties and dwarf varieties, then into round and wrinkled, yellow and green, etc., but it would be logically as sound and physiologically as justifiable to divide them first into yellow and green, then into early and late and so on. If the races of men could be crossed under experimental conditions we should find the same principles governing their distinctions.

Applications.—The applicability of genetic discoveries to the betterment of the human race is discussed in the article EUGENICS, but progress in the art of breeding animals and plants is also possible by the development of Mendelism. The use and consequences of crossing in the search for new forms of economic value are now apparent. The reasons for preserving the first generation (F_1) though it may present no valuable feature and the desirability of raising from it as many individuals (F_2) as space will accommodate, are obvious. The breeder now knows what he is about and is able to interpret countless phenomena previously meaningless. Granting that the chief breeds of animals now in the keeping of civilised man are not capable of much amelioration, experience has shown that enormous improvements can be made by applying accurate knowledge to the breeding of even such old-established crops as wheat, oats, tobacco, etc. If this is true of the crops which have for ages been the object of unremitting care, it will be understood that the cultivated plants of tropical regions offer limitless possibilities.

The breeding of coconut, rubber, jute, cacao and many more has scarcely begun. These are all still raised from seed gathered almost promiscuously, the result of uncontrolled fertilisation, and the product is what we should see if our orchards were raised from seeds and those seeds gathered at random from garden varieties and from wildings in the hedgerows. At first, selection and fertilisation under control will suffice to make great progress. Even at that stage some genetic knowledge will be of value, but when the more difficult task of making genetic recombinations of desirable qualities is begun the breeder will require skill in the management and interpretation of the generations and the various terms in the series of forms which only accurate knowledge of principle can supply. Genetic science shows primarily what can be expected, provides the breeder with an aim, and also indicates how it may be attained. For example, a crop of sugar beet often contains 4% (sometimes many more) of plants which "bolt" or flower in the first year making no "bulb," and so worthless. This state of things has long been accepted as inevitable.

But when the geneticist finds that the annual habit is a recessive, he suspects that the plants which produce the bolters are heterozygous in that respect, and that if he can raise plants homozygous in the biennial habit he will have eliminated bolting. The breeder, whether scientific or practical, ignorant of genetics, would never suspect the nature of the fault, still less could he devise a cure. Common sense in the art of seed-raising is an imperfect guide. Apart from any question of making new races, the purification of existing varieties and their maintenance in a state of purity are exacting tasks. What has been done in these several phases of the industry, in ignorance of principle, is remarkable, but we may confidently foresee that the application of scientific method will, in the case of the breeder's art, effect a change in magnitude no less than that which has been witnessed in the other industries.

MENENDEZ PIDAL, RAMÓN (1869–), Spanish philologist, was born March 13 1869 at Corunna, and studied at the universities of Madrid and Toulouse. In 1899 he was appointed to the chair of romance philology at the University of Madrid. Menendez soon acquired a great reputation as a master of his subject and lectured in South America and the United States. In 1907 he was member of a board created in that year for the development of university education in Spain and in 1913 was appointed counsellor of public instruction for the kingdom. His grammar, text and vocabulary of the *Cantar de Mio Cid* (1908) opened out new possibilities not only to Castilian philology but to historiography in general. Menendez Pidal became the leader of the *Centro de Estudios Históricos*, the main house of learning in philology and historical matters in Spain, and the editor of the *Revista de Filología Española*. His other works include *Primera crónica general* (1906); *L'épopée Castillane à travers la littérature espagnole* (1910); *Gramática Histórica Española* (1914); *Un aspecto en la elaboración del Quijote*, 2nd ed. (1924).

MENÉNDEZ Y PELAYO, MARCELINO (1856–1912), Spanish scholar and critic (*see* 18.128), was at the time of his death working at the second edition of his *Historia de los heterodoxes españoles*. He died at Santander May 19 1912.

See A. Donoso, *Menéndez y Pelayo y su Obra* (1913); Bonilla y San Martín, *Menéndez y Pelayo 1856–1912* (1914); and A. G. de Amezua y Mayo, *Nota bibliografica de Menéndez y Pelayo* (1918).

MENTAL DEFICIENCY.—Mental deficiency, or amentia (*a*, without, *mens*, mind), has been defined as that state in which the mind has failed to attain normal development, as distinguished from dementia (*de*, down from, *mens*, mind), mental defect occuring subsequently to mental development. Legislation both in England and abroad has recognised the essential difference between these two forms of mental disease, and the class of so called "mental defectives" is generally dealt with by laws differing from those affecting the insane. These laws are based mainly on a recognition of (*a*) the educational, (*b*) the social and racial problem created by the presence of large numbers of uncontrolled mentally defective persons in the community.

I. GREAT BRITAIN AND THE BRITISH EMPIRE

In England the Mental Deficiency Act of 1913 was the outcome of the Report (1912) of the Royal Commission on the Care and Control of the Feebleminded appointed in 1908, and embodied a considerable number of its recommendations.

The Elementary Education (Defective and Epileptic Children) Act, 1899, gave to local education authorities power to provide special schools (day or residential) for mentally defective children between the ages of 7 and 16 who, not being either dull or backward or idiots or imbeciles, were capable of benefiting by the education provided in such schools. Under the Elementary Education (Defective and Epileptic Children) Act of 1914 these powers were made compulsory, and both Acts were embodied in Part V., sections 51–9 of the Elementary Education Act 1921. Attendance at such schools may be enforced by a magistrate, provided it is clearly for the child's benefit that he should attend a special school. Owing to the War and to the relatively high cost of these schools many authorities have failed to provide sufficient, in some cases, any, special schools; there is practically no school provision for defective children in rural areas. The estimated number of defective children is calculated at 8 to 10 per thousand of the school population. The latter figure is probably the more accurate. This gives a total of 50,240 defective children to be provided for, but provision has only been made for 16,392 children in 174 day and 21 residential schools. In addition, the local education authorities must notify to the local control authority children who are incapable of benefiting from education in special schools or who need institutional care on leaving school. In urban areas there are 88 occupation day centres for children excluded from schools, run for the most part by local voluntary mental welfare associations; after-care committees and the above associations look after the children who have left special schools, try to find them employment, supervise them at home and establish handicraft centres for them.

The Mental Deficiency Act.—The Board of Control, a section of the Ministry of Health, administers the Lunacy and the Mental Deficiency Acts. The local control authorities are statutory mental deficiency committees of county and county borough councils, whose duty it is to provide for defectives,[1] only when they can be certified as idiots, imbeciles, feebleminded or moral imbeciles, and who in addition are either (*a*) neglected, without visible means of support, cruelly used, etc.; (*b*) found guilty of any criminal offence, and liable to be sent to or actually sent to an industrial school or prison; (*c*) notified by the local education authorities as ineducable or as needing institutional care on leaving a special school; (*d*) having given birth to or being pregnant of an illegitimate child whilst in receipt of poor relief. The duty of the authority is to (*a*) ascertain the defectives they must deal with; (*b*) provide supervision by visiting and watching over the defective at home. This supervision is in a large number of areas carred out by local mental welfare associations affiliated to the Central Association for Mental Welfare, who supply visitors for defectives living in the community. If this supervision is insufficient the authority may (*c*) send defectives to a certified institution under orders, or (*d*) place them under guardianship under orders, *i.e.*, under the charge of an individual having the powers of a parent over them. This order is made by a magistrate on a petition supported by two medical certificates. Orders are renewable by visiting justices at the end of each of the first two years, then every five years. So long as the order lasts the defective can be compulsorily detained, but defectives can be discharged by a commissioner of the Board of Control at any moment. The parents of defectives, if they oppose the making of the order, must prove that it is for the benefit of the defective that he should remain at home.

Local authorities are required to provide certified institutions for defectives; they can also send defectives to institutions provided by other committees. The War prevented the development of institutions, and a considerable number of poor law institutions have been approved for the reception of defectives under orders. The Royal Commission estimated that there were 4·6 per 1,000 defectives in the population. Some 48,778, or 1·29 per 1,000, have been ascertained, but only 19,076 defectives were in institutions under the Act in Jan. 1926, many being found in institutions and homes as rescue cases, paupers, etc.

The difficulties are: incomplete ascertainment of defective children, which handicaps preventive measures; lack of special educational facilities for training defectives; lack of institution accommodation for adult defectives; and lack of recognition of mental defect in cases coming before the courts. Greater efforts are being made to safeguard the community and the defective by segregating all with anti-social tendencies in institutions.

Scotland.—The Mental Deficiency Act for Scotland, 1913, does not differ very materially from the English Act but the local authorities are local boards of control and the parish councils. There were 2,452 certified mental defectives on Jan. 1 1925. A Scottish Association for Mental Welfare was established in 1922. There is also an active voluntary movement on foot for the establishment of a large colony for the feebleminded.

Ireland.—The Mental Deficiency Act does not apply to Northern Ireland. There was in 1926 but one institution for efectives in the whole of Ireland, but certain religious communities propose to open others.

---

[1] For definitions see the Mental Deficiency Act.

British Empire.—Legislation in other parts of the British Commonealth is generally modelled on the English Mental Deficiency Act. In South Australia, a Mental Deficiency Act was passed in 1913; n Tasmania, in 1920. The Mental Deficiency Board then establshed published in 1925 a report on a mental survey of the prisoners n Hobart Gaol. In Melbourne and Sydney special schools and lasses for mentally defective and backward children are being stablished.

The Mental Disorders Act of 1916 regulates the care of defectives n the Union of South Africa. A national council for the care of the eebleminded watches over the interests of individual defectives, and uides public opinion.

In Canada a Federal Act dealing with immigration prohibits the ntry of mental defectives into the country. Each provincial governent provides grants for the organisation of special classes for mental eficients in school attendance, and in Jan. 1926 there were approxiately 140 such classes. Ontario, Alberta, Saskatchewan, Manitoba nd Nova Scotia have made institutional provision for approxiately 1,500 mental defectives, the largest at Orillia, Ontario, having ccommodation for 1,200 cases. Several of the larger cities, including oronto, Winnipeg and Vancouver, provide routine mental examations for schoolchildren and for juvenile court cases, and since 918 the Canadian national committee for mental hygiene has been onducting surveys throughout the Dominion to determine the revalence and significance of the problem.

In New Zealand, the Mental Defectives Act of 1911 and the ducation Act of 1914 are the Acts under which day schools, one or wo residential schools and some institutions are established. A ommittee of enquiry (1925) under the Ministry of Health recomended the establishment of a eugenic board for the compilation of a egister of mental defectives, and made recommendations for the erilisation of certain mentally defective persons.

II. THE UNITED STATES

Americans have given a great deal of study to the proper iagnosis and training of mentally defective persons and to the ugenic aspects of the problem, and there is a very widespread nd efficient organisation in many of the States. Each State as its own legislation. There are numerous special day schools, alled auxiliary classes, residential schools and institutions. Iany of the institutions are on a vast scale, and have thus peritted interesting experiments. One of the pioneers of the work, e late Dr. Walter Fernald, developed the Waverly Institution Mass.) into a highly successful training colony. One of Dr. ernald's principles was "paroling," and a very large number of atients, especially men, did remarkably well on "parole" from he institution. Institutions equally interesting are the Rome tate School (New York) and Vineland (New Jersey), where r. H. Goddard and Dr. S. D. Porteus have carried out numerous xperiments in the measurement of intelligence. Psychiatric inics are attached to many hospitals, and afford considerable pportunities for the study of mental defect. Segregation has been ied on a wide scale in several of the States, and for some years ertain States have had laws allowing the sterilisation of mental efectives. Special attention has been directed to the whole roblem of defect in its relation to delinquency amongst children nd adults. The national committee for mental hygiene and the int committee on methods of preventing delinquency, the udge Baker Foundation, Boston, Mass. (which publish nuerous monographs) and other kindred associations have done ioneer work in this connection.

III. EUROPEAN COUNTRIES

The work among mentally defective persons in other countries llows much the same lines as are indicated in the description ven below. The classification of defect differs somewhat in fferent countries, and a class of "moral imbeciles" is not niversally recognised. Almost all countries have now made me provision for mentally defective persons, but the problem still inadequately met.

France.—In France, mental defectives are dealt with under the w for "aliénés" passed as long ago as 1838, which has not been mended. Under this law persons can be placed in institutions at e request of their families, or by order of the prefect, if they are onsidered dangerous or in need of protection. Some difficulty is und in dealing with cases needing treatment but not institutional care, but the work of treating the feebleminded at psychiatric clinics is likely to develop since the establishment of a clinic at Paris in 1921. A law passed in 1919 recommends special classes for children, but does not make them compulsory. No statistics as to the incidence of defect are available. Some French institutions have a fine reputation, notably perhaps the Hospice de Bicêtre, near Paris, which is attached to a general hospital, and has accommodation for about 1,000 males (mostly idiots and imbeciles) and about 217 girls. Seguin, one of the pioneer teachers of defectives, worked at the Bicêtre.

Italy.—In Italy, the class "imbecili morali" is recognised. No exact figures are available as to the number of defectives. A general law on the protection of children was in preparation in 1926. There are only eight institutions set aside for the mentally defective, accommodating 761 persons. Madame Montessori's educational methods (q. v.) were based on the experience gained among defective children at Rome. She made the startling discovery that a mentally defective child taught on her methods was in some instances actually able to attain a higher standard than normal children taught on other methods. She has applied to the teaching of normal children the empirical methods so effective with defectives, and her work has reacted in favour of improved methods for both classes of children.

Belgium.—Another educational pioneer, Dr. Ovide Decroly of Brussels, similarly first interested himself in the study of defectives, and later adapted his methods in use in his special school in Brussels to the teaching of normal children. His normal school in Brussels reveals its purpose by its title, "École pour la vie par la vie," and his methods have been adopted in many of the elementary schools in Brussels. Belgium has a remarkable institution, the colony at Gheel, whose origin goes back to the 6th century, when a shrine was built to St. Dymphna, a martyred Irish saint. At least as early as the 13th century she came to be considered the special saint of "aliénés." From that time through the centuries the work has grown until today Gheel is a place of some 20,000 inhabitants caring for 2,000 "aliénés," including insane and mentally defective, with a school for 160 defective children. The principle of the colony is freedom and home-life in the families of the citizens. Other similar colonies have been founded in the country.

Holland.—The institutional care of the feebleminded is almost entirely in private hands, but special schools exist in the towns.

The Scandinavian countries have a good system of special schools and several institutions, and considerable attention has been given to the training of defectives.

Denmark.—It is estimated that there are in Denmark between 6,000 and 7,000 mentally defective persons in a population of 3,500,000, but there are no exact statistics. There are four large institutions, accommodating about 3,450 persons, and private homes taking 350 patients. Special schools are not compulsory, but they are established in most large towns such as Copenhagen, which has a school for 700. A Marriage Act is on the statute book prohibiting marriage with a mentally deficient person.

Austria.—Developments in Austria have been considerable since the War. There are special schools and classes for 2,794 children, and 20 institutions for the care and instruction of 1,498 mentally defective and epileptic children.

Germany.—Germany has a fine special school system, with schools in about 600 different places. These schools are in some instances very small, more than 200 having only one class, and 150 only two classes. There are in all about 3,500 classes in these schools, with accommodation for 67,000 children. Most of the special schoolchildren have had two years' trial in the elementary school, and those who are not able at the age of six to profit by the elementary school can attend a "Vorklasse" before being drafted into a special or normal school according to their development. In Mannheim since the beginning of the century, and later in Charlottenburg, Frankfurt-on-Main and other towns, a system of so called "Förderklassen" has been established for the backward child whose mental difficulties may be due to exterior or physical causes and not to mental defect. In other towns there are classes for those who in the later years of school life remain backward.

Switzerland.—The Institut J. J. Rousseau in Geneva has been of inestimable value in the scientific study of the child. The founder, Prof. Ed. Claparède, has proceeded on the principle that the abnormal and normal child should be studied at the same time, and the institute has now become a laboratory for the study of the child in all his manifestations. The care of the feebleminded is very well organised in Switzerland. In 1918 preparatory classes were established for the children who cannot keep up with the lowest class, and in some schools there are "crammer" classes with more handwork than in the ordinary classes, for children whose backwardness is due to "neglect," and who are probably able to return later to the ordinary classes. There are also "work-classes," which have more manual work even than the special schools. The employment schemes in institutions are admirably organised. The Basle institution, opened in 1916 for the paid employment of defectives has been most successful, and is being enlarged so as to serve the needs of defectives from any area. A work and welfare home for girls, with similar aims, was opened in 1924 at Komtz, near Berne.

MERCIÉ, MARIUS JEAN ANTONIN (1845–1916), French sculptor and painter (*see* 18.152), died in Paris Dec. 12 1916.

MERCIER, DÉSIRÉ (1851–1926), Belgian cardinal, was born Nov. 21 1851 at Braine-l'Alleud in the Walloon part of Brabant, of a bourgeois family. He studied at the episcopal college of St. Rombaut, Malines, and at the lesser seminary of that town. On April 5 1874 he was ordained priest after following the courses of the larger seminary, where he made his first acquaintance with the philosophy of St. Thomas Aquinas. After two years at the University of Louvain, he was appointed professor of philosophy at the lesser seminary of Malines (1877). In 1880 Leo XIII., who wished to promote the study of Thomism, invited Cardinal Dechamps, Archbishop of Malines, to found a chair of Thomist philosophy at Louvain. The choice of the Cardinal fell on the young Abbé Mercier, who was appointed in 1882. Before assuming his new duties, the new professor studied in Paris under Charcot. While teaching psychology, logic, criteriology, metaphysics and ontology to his Louvain students, including a large number of laymen, he followed closely the research work of his colleagues, according to the tradition of the scholasticists, who combined theological and scientific studies.

In 1886 the Pope conferred a Roman prelateship upon him, and in 1888–9 issued two briefs urging the necessity of founding an Institut Supérieur de Philosophie at Louvain. This institute was finally opened in 1894 and included, besides the chair of philosophy held by Mgr. Mercier, chairs of cosmology, physics, sociology, etc., held first by his colleagues and later by the pupils he had formed. The institute published the *Revue Néo-scolastique* and became the centre of Neo-Thomism which exerted considerable influence on Catholic thought all over the world. In 1906 Mgr. Mercier was appointed Archbishop of Malines, and in 1907 he was created a cardinal. He used his influence with his priests and his flock to break down the barriers existing between the members of the clergy and the laymen, to eliminate all class distinctions between the Catholic bourgeoisie and the labourers, and to bring about a better understanding between Catholics and non-Catholics.

On Aug. 20 1914, while the Belgian Army was retreating upon Antwerp and the Germans were entering Brussels, the Cardinal was abruptly summoned to Rome to take part in the election of a successor to Pius X. Shortly after his return to Malines, he issued a pastoral letter, "Patriotism and Endurance," in which he protested against the burning of Louvain and the other excesses committed by the German Army, and in which he defined the position of the Belgian people towards the occupying Power. While, according to him, the Belgians owed, in soul and conscience, neither respect nor allegiance to this authority, which was not lawful, they had to accept German regulations so long as they did not violate their duty to their country, the army alone having the right to resist openly the invaders' power. In spite of the pressure exerted upon him by the German authorities, he maintained the same attitude throughout the period of occupation, protesting publicly in his sermons and pastorals against the arbitrary decrees of the governor-general, especially concerning the deportation of workmen and the administrative separation of the country, urging the people, at the same time, to remain confident in the final victory of their just cause. In Jan. 1916 the Cardinal took a second journey to Rome where he was received with enthusiasm, and brought back with him a most cordial message from the Pope. He proclaimed, in his next pastoral letter, that "The moral triumph of Belgium, i the eyes of civilisation and history, is already an accomplishe fact." In Oct. 1918, on the eve of the retreat of the Germa troops, the Cardinal received a message from the Governo greeting him as the "revered spiritual leader of the Belgia people" and announcing to him that political prisoners an deportees would shortly recover their liberty.

After the War, the name of Cardinal Mercier was associate with informal conversations which took place at Malines following the "appeal to all Christian people" issued by the Lambet Conference of 1920. He took a prominent part in these friendl discussions between representatives of the Roman and Anglica Churches. The first conference took place between Cardina Mercier, Mgr. van Roey (his successor as archbishop of Malines) and Abbé Portal, on the one side, and the Dean of Wells, th Bishop of Truro (Rev. W. H. Frere) and Lord Halifax on th other. Bishop Gore, Dr. B. J. Kidd, Mgr. Batiffol and Abb Hemmer took part in the third Conference, held in 1923. A fu account of these conversations, which concentrated on doctrina and historical rather than on administrative questions, wa issued by the Archbishop of Canterbury at the end of the sam year. In the spring of 1924 Cardinal Mercier celebrated th jubilee of his ordination. He died in Brussels, after an operation on Jan. 23 1926. (E. Ca.*)

MERESJKOWSKY, DMITRI (1866–), Russian man o letters, was born in St. Petersburg (Leningrad), the son of court official, and graduated from St. Petersburg University He married Zinaida Hippius, the poet. His first volume of poem appeared in 1888 and was followed by more poetry, *Vera*, *Sakya Muny*, *Avakum*, *Black Angel*, etc., by translations from Euripide and other Greek classics, by literary essays on Russian and foreign writers, old and new, *Eternal Companions* (1897), and trilogy of historical novels under the general title *Christ an Antichrist* (1902–5); *Julian the Apostate* (1895), *The Renaissanc of the Gods*, *Leonardo da Vinci* (1902), *Antichrist*, *Peter an Alexis* (1905). After the "trilogy" came the novels *Alexande I.* (2nd ed. 1913), *December 14*, and—in connection with th Tutankhamun excavations—*The Birth of the Gods*. Abou 1900–2 Meresjkowsky evolved a mystic, neo-Christian o apocalyptic teaching based on the equal sanctity of flesh an spirit as opposed to the cult of the flesh as represented by paganism, and the cult of the spirit as revealed by ecclesiastica Christianity. His other writings include works of literary criticism, *Tolstoy and Dostoievsky* (1901). He also wrote on religious political and social questions, and published several plays After the revolution Meresjkowsky left Russia and went to liv in Paris, where he continued his literary activities.

Meresjkowsky's collected works were published in 24 vol. i 1914. The following were translated into English: *The Death of th Gods* (1901), *Peter and Alexis* (1905), *December 14* (1923), *The Forerunner* (1924), *The Birth of the Gods* (1925). See also Jean Chuzeville *Dmitri Meresjkowsky* (1922).

MERRIMAN, JOHN XAVIER (1841–1926), South African politician, was born March 15 1841 at Street, Somerset, England His family moved to South Africa in 1849, and John Xavier was educated at the Diocesan College, Rondebosch, and later at Radley College, England, returning to the Cape in 1861 Merriman entered politics in 1869. Three years later, despite his opposition, the Cape obtained self-government, and in 1875 he joined the Molteno Ministry as commissioner of public works When in 1877 war with the Galeka Kaffirs broke out Merriman became virtually Secretary for War in the Cabinet.

Merriman came into office again in the Scanlen Ministry (1881–4), again as commissioner of public works. The dubious attitude of the newly-formed Afrikander Bond to the British connection alienated him from the Dutch extremists. The Bond had caused the fall of the Scanlen administration because the Ministry opposed the attempt of the Transvaal Boers to seize Bechuanaland; and when Rhodes formed a Ministry in 1890 Merriman joined it as treasurer-general. Meanwhile the Bond had adopted a constitutional programme, and 1890 saw a drawing together of the Dutch and British elements at the

Cape. But the Uitlander troubles in the Transvaal became acute, ınd in 1893 Merriman resigned. He was chairman of the Cape parliamentary committee which inquired into the Jameson raid of 1895, and drew up its report. The general election in Cape Colony in 1898 gave the Bond a very narrow victory, and W. P. Schreiner became Prime Minister, with Merriman treasurer-general again, though the latter was not a member of the Bond. Merriman was among the ministers who in 1900 opposed the neasure to disfranchise the Cape rebels, and this led Schreiner o tender the resignation of the Cabinet. At the general election of 1904 Merriman was defeated, but was returned shortly afterwards at a by-election. In Jan. 1908 he succeeded Dr. ameson as Prime Minister and treasurer-general (*see* 5.247). Merriman was a member of the national convention which ıammered out the new constitution. On the establishment of he Union in 1910 he did not join the Union Ministry under Botha *see* SOUTH AFRICA), remaining a somewhat detached member of he South African party. He opposed the disruptive policy of Hertzog as strongly as he had formerly supported the independ-nce of the Boer republics. He died Aug. 2 1926.

MERRITT, WESLEY (1836–1910), American soldier (*see* 18.-73), died at Natural Bridge, Va., Dec. 3 1910.

MERRY DEL VAL, RAPHAEL (1865–), Spanish ecclesias-ic and diplomat, was born Oct. 10 1865 in London, where his ather was secretary to the Spanish Legation. He was educated t Baylis House, near Slough, and at Ushaw College, near Dur-am. Ordained priest in 1888, he began at an early date to spe-ialise in diplomatic work for the Vatican. In 1892 he became laster of the Robes and acting private chamberlain to Pope Leo XIII., of whom he was a great favourite. In 1897 he was sent to anada to report on the difficult Manitoba schools question, nd accomplished this mission with conspicuous success. In 900 he became Archbishop of Nicea. He was Secretary of the acred College of Cardinals during the election of Pius X. (July 903) under whom he became Cardinal and Secretary of State. n Jan. 12 1913 he succeeded Cardinal Rampolla as Archpriest f the Basilica of St. Peter's, Rome, and in the following year as appointed Secretary of the Supreme Congregation of the oly Office by Benedict XV. In Dec. 1920 Cardinal Merry del al became Camarlingo of the Holy Roman Church.

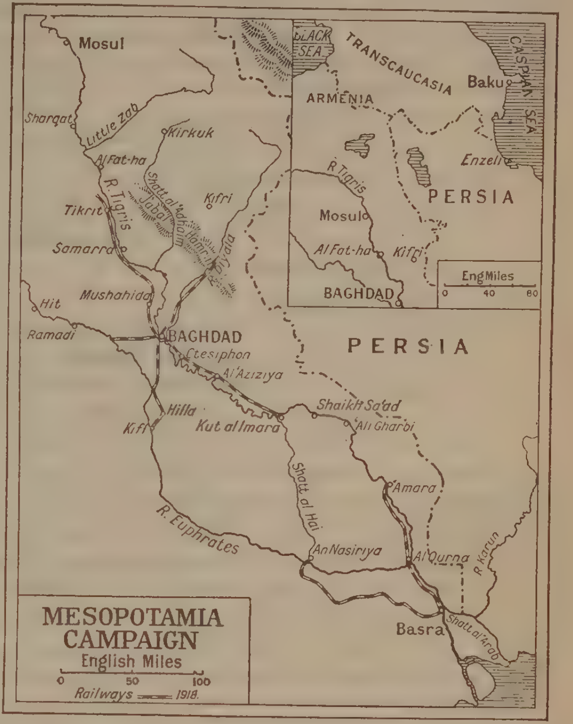
MESOPOTAMIA: *see* ʻIRAQ.

MESOPOTAMIA, OPERATIONS IN.—The Anglo-Indian opera-ons of 1914–8 in Mesopotamia were in their initial stages con-eived on comparatively speaking modest lines. The object at e outset was merely (1) to protect the Anglo-Persian oil instal-tions, (2) to occupy the greater part of the Basra vilayet so as to cure possession of the Shatt al ʻArab and the districts imme-ately round the head of the Persian Gulf, and (3) to impress e Arabs and others in this region and in the territories inter-ening between the Ottoman Empire and India. Steps had al-ady been taken before relations between the Entente Powers d the Porte were actually broken off, and a brigade of the 6th dian Div. had been dispatched to an island near the head of e Persian Gulf. Then, on Nov. 7, two days after the British claration of war on Turkey, these advanced troops appeared their transports at the mouth of the Shatt al ʻArab.

The fort guarding the entrance was taken, and the brigade camped some miles up the stream on the right bank. On arning this, the Turks hurried all available forces down from asra; but, the rest of the 6th Div. having arrived under Sir Barrett, they were on the 17th attacked and overthrown. asra fell on the 21st, and Barrett then promptly pushed troops to Al Qurna, which was taken on Dec. 9. As considerable rkish reinforcements were arriving from Baghdad, he was not together comfortably situated; but the Osmanlis were not in aggressive mood, and the invaders were little interfered with ring the first three months of 1915. The Indian Government March decided to raise the expeditionary force to the strength an army corps by adding the 12th Indian Div., and early in ril Sir J. Nixon took over command from Sir A. Barrett, who d made the most of the limited means at his disposal, General wnshend at the same time taking over the 6th Division.

I. THE BRITISH ADVANCE UP THE TIGRIS

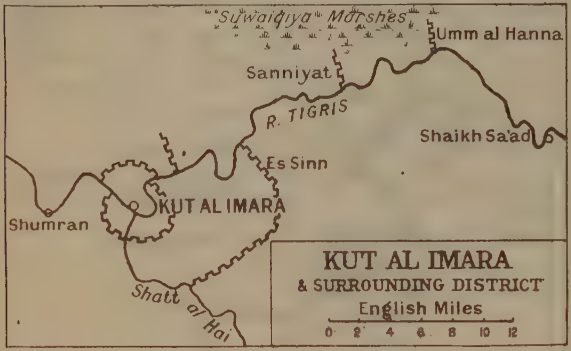
During the latter part of April the Turks showed a marked increase of activity; but all their offensive efforts were frustrated, and Nixon, encouraged by these successes, decided to occupy Imara, 60 m. north of Al Qurna on the Tigris. The task was entrusted to Townshend, who carried it out by making free use of water transport for moving his troops, and who made himself master of the place on June 3, capturing 17 guns and 1,800 prisoners. Nixon now resolved on a blow against An Nasiriya, on the Euphrates, and the 12th Div. took possession of that town on July 25, capturing another 17 guns and 1,000 prisoners. The expeditionary force could then claim that it had effectually achieved the object for which the campaign had originally been undertaken, and its triumph was all the more creditable in view of the lack of transport and the inadequacy of its administrative service. The military organisation of India had not in pre-War days been framed with the idea of prosecuting martial operations overseas on an ambitious scale, and, as it was, the Government had accepted heavy commitments in Europe, in Egypt and in East Africa, in addition to the undertaking in lower Mesopotamia. There was a lack of reserve, the medical service had been starved, and the necessary military resources for an extension of the Mesopotamian operations were in reality deficient.



Occupation of Kut.—The authorities at Simla had unfortunately been inspired, by Barrett's and Nixon's successes, with the desire for adopting a more ambitious programme than that contemplated at the outset. They readily fell in with Nixon's proposal to advance up the Tigris to Kut al Imara—180 m. up-river into the heart of the enemy's country—and early in Aug. Townshend, with the 6th Div., began pushing forward from Imara. On Sept. 15 he drove an advanced Turkish force out of a position on the right bank of the Tigris about 15 m. from Kut, and on the 28th completely defeated the enemy a little farther on at Es Sinn, taking 1,650 prisoners, 13 guns and much war material. Kut was occupied, and the cavalry pursued the fleeing Osmanlis as far as Al ʻAziziya, half way to Baghdad.

Kut was a place of strategical importance, because at this point the Shatt al Hai, issuing from the Tigris, created a link with the Euphrates near An Nasiriya, and provided the line of communications which would naturally connect Turkish forces on the lower Euphrates with Baghdad. It was furthermore the most populous spot between Imara and An Nasiriya on the one hand, and Baghdad on the other. But almost the whole of the expeditionary force, apart from detachments on garrison duty lower down, had now been projected into an isolated situation far within the enemy's territory, and it depended upon a long line of water communication—the Tigris—while it was served only by a restricted number of steamers and of smaller craft.

Still, the idea of pushing on to Baghdad had already taken shape even before the occupation of Kut. The Aug. discomfiture in the Gallipoli Peninsula (*see* DARDANELLES CAMPAIGN), coupled with a belated realisation that the Dardanelles venture would not succeed, had rendered the British Govt. eager for some dramatic achievement in Mesopotamia. The Indian Viceroy had advocated an advance on Baghdad when the start up the Tigris from Imara was materialising, and Townshend's triumph acted as a powerful stimulus to such aspirations. Nixon intimated early in Oct. that he could open a road to Baghdad, under the circumstances then existing, but could not hold the city if it were taken. The military authorities at home, while admitting the possibility of capture, regarded permanent retention as out of the question with the limited numbers available, and they declared that if the place was to be held Nixon must be reinforced by two divisions. But, influenced by political considerations, the Government became more insistent, and in the end, although no reinforcements could be sent him immediately, and although they could not have taken part in the operations had they been sent, Nixon was told on Oct. 31 that he might advance on the city.



First Baghdad Offensive Fails.—Townshend, who had pushed a large part of his force on to Al ʻAziziya while the matter was being debated, found that the Turks were less disorganised than had been supposed, and that his own troops were tired and short of establishment; and he had serious misgivings. He, moreover, was unable to move for a fortnight, even after receiving the order to advance, owing to shortness of supplies and the need of organisation for the hazardous effort. He advanced from Al ʻAziziya on Nov. 11, and on approaching Ctesiphon some days later he found the Turks to be assembled there in strong force and expecting reinforcements. He attacked them on the 21st and was at first successful; but additional Ottoman troops arrived during the fight and recovered much of the lost ground, Townshend's losses in the action proving very heavy. During the next three days Townshend prepared to retreat, and on the night of the 25th he moved off.

No great difficulty was experienced at first; but, in consequence of the flotilla of supply transports and fighting craft being delayed by shoals, a halt had to be called on the 29th. Next day the pursuing Turks came up and delivered a resolute attack which was however beaten off, and after that the sorely tried little Anglo-Indian army was not seriously interfered with on its way to Kut, which was reached on Dec. 3. So, for the moment, ended the ill-advised Baghdad adventure. During the discussions of Oct. the Turks had been strongly reinforced from the northwest, and, by the time that Townshend had advance from Al ʻAziziya, his adversaries had already grown so form dable that there was little prospect of his opening a road to t city. There never had been any prospect of his being able hold the place even if he got there. Seldom has a military for been committed to an undertaking that seemed so difficult attainment.

II. The Siege of Kut

With the approval of the Home and Indian Government Nixon decided that Townshend was to remain where he wa although if he did so he was bound to be invested. They assume altogether too readily, that he would be relieved before his su plies ran out. So his sick and wounded, his cavalry, most of t flotilla, and a portion of his animals were sent off down the Tigr (although the civilian population was unfortunately allowed stop), preparations for standing a siege were put in hand, and Dec. 8 Kut was hemmed in on all sides. Its situation, in a de loop on the left bank of the Tigris, rendered the place readi defensible against assault or siege approach, and the Germa Field Marshal von der Goltz, who had just taken supreme co mand of the Ottoman forces in Mesopotamia, realised that unle it fell to an early assault the main Turkish task in this regi would be to guard against a relief. Nur-ed-Din, the Turki commander on the spot, had four divisions at his disposal, a on Dec. 10, 11 and 12 he delivered unavailing onsets upon t narrow front that was not covered by the river. After that t siege became a blockade, part of Nur-ed-Din's troops mov down the river some distance so as to confront any relievin force that might try to approach, and fortifications designed meet such a contingency were erected.

Attempts at Relief.—Meanwhile the 7th and 3rd Indian Di sions had been detached from the Western Front in Europe, a began arriving in the middle of Dec. in the Shatt al ʻArab. Ge eral Aylmer took charge of the troops who were to underta the relief of Kut, and units as they disembarked were push on to Imara with all speed and proceeded thence up the Tigri Owing to a miscalculation as to the length of time that K would be able to hold out, the operations of relief were duri their early days hurried more than was necessary, with the r sult that the force under Aylmer was during its operations Jan. less well organised than it might have been. There was grievous lack of heavy artillery, as well as a grave deficiency water transport. Nevertheless the Turks were driven out their advanced position at ʻAli Gharbi, were again defeated Shaikh Saʻad and, after a further defeat, fell back to the lin of Umm al Hanna, 20 m. from Kut on the left bank of t Tigris, at the entrance to a very awkward defile caused by t extensive Suwaiqiya marshes, which here approach to within short distance of the river. The relieving force had hither triumphed over every obstacle; but when on Jan. 21 it essay the storming of the Umm al Hanna position the effort faile and so numerous were the casualties that Aylmer felt compell to pause in his offensive and to await reinforcements. Abo the same date Sir P. Lake succeeded Sir J. Nixon in the chi command.

Improvement of Organisation.—Lake set himself to place A mer's line of communication on a better footing, to improve t medical arrangements and to develop the wharves at Al Qur and Basra. Material of all kinds was, however, deficient, and t Turks were in the meantime developing their lines of defence both banks of the Tigris below Kut, rendering the task of a r lieving force more and more difficult. The British Governme had, on receipt of the bad news about Umm al Hanna, order the 13th Div. to proceed from Egypt to Mesopotamia; but move these troops from Suez to the front of the Tigris necessari took some weeks, and it was moreover now too late to expa the water transport sufficiently to meet the needs of the growi Anglo-Indian force. Aylmer attempted no forward moveme during Feb.; but on the night of March 7–8, without waiting the 13th Div., he advanced from near Shaikh Saʻad against t Es Sinn position, intending a surprise.

This was on the right bank of the Tigris, less than 10 m. from ut, considerably higher up than Umm al Hanna and the defile aused by the Suwaiqiya marshes on the farther bank; but owing the Turks holding that defile Aylmer's flotilla was prevented om advancing above Umm al Hanna. The operation involved long march in the dark; when day broke part of the force had ot arrived, and, although the enemy was surprised in the first stance, the attack was delayed. When the assailants advanced gainst the reinforced Turks, they were beaten back and had to tire to Shaikh Saʿad.

Surrender of Kut.—The garrison of Kut was already on much duced rations; but Gen. Gorringe, who had succeeded Aylmer, ould make no fresh attempt for nearly a month owing to transort and supply problems. On April 5, however, the 13th Div. nder Gen. Maude stormed the Hanna lines and penetrated ell into the defile on the left bank of the Tigris; but, when rst the 7th Div. and then the 13th Div. attacked the Sanniat lines at its farther end, they were in each case repulsed. ut could now only hold out a few days longer, so Gorringe ied to advance by the right bank. After its making some rogress on the 17th, in spite of almost insuperable difficulties aused by floods, this movement was, however, brought to a andstill. A final effort was made by the 7th Div. on the 22nd gainst Sanniyat, which nearly succeeded. Finally, on the ght of the 24th, a steamer loaded with provisions tried to run e blockade but failed, and on the 29th Kut, with its garrison 9,000 British and Indian troops, surrendered. The efforts to ve it had cost 24,000 casualties, but had it been known in n. and Feb. that the place could have held out so long, the lieving army would have enjoyed a better prospect of achievg its object.

British Opinions.—The tidings of this very grave mishap gave se to profound dissatisfaction in Great Britain, a dissatisfaction gravated by information gradually leaking out with regard to e sufferings of the sick and wounded after the retirement from tesiphon. A Royal Commission was set up a few months later inquire into the operations that had taken place in Mesopomia, and its conclusions were to the effect that the undertaking a campaign on so ambitious a scale without adequate foreought and efficient preparations was worthy of blame; it also imadverted in strong terms on the very unsatisfactory charter of the medical arrangements during the early stages of the nture. In the meantime it was decided that Kut must if posble be reoccupied. But the hot season was at hand. The oops had suffered exhausting trials and had met with cruel sses. Water transport, as well as artillery and other war matel, remained totally inadequate. There could be no question resuming the offensive on the hand-to-mouth lines on which e advance from Imara had been initiated in the previous ar, and which General Lake had been obliged to continue when iving against time to relieve Townshend. A prolonged pause erefore became inevitable.

No reference has been made hitherto to the Russian forces in rsia. These, based on the Caspian, were actually in occupaon of a considerable area of the Shah's northern territories. ut they were weak in numbers, were operating in a region of de extent, and the avenues leading towards the Mesopotamian ain traversed rugged and unproductive uplands. Military ntingents so situated could afford no direct help to the Anglodian army during the critical months which followed Townsnd's advance to Kut, nor did their activities at any time withaw an appreciable proportion of the forces under Von der Goltz om the theatre of war on the Tigris.

III. THE BAGHDAD OFFENSIVE

Great developments took place on the Anglo-Indian line of mmunications, and at the base during the summer. A reanable amount of heavy artillery was gradually accumulated. additional division arrived from India. Landing facilities at e ports were vastly improved. A change, moreover, took place the chief command, for, after replacing Gorringe in charge of e forces at the front in July, Gen. Maude a few weeks later became commander-in-chief *vice* Sir P. Lake, whose health had broken down. Maude realised that there was yet much to be done before his army could hope to act with effect in this peculiarly conditioned theatre of war, and he set to work with indomitable energy to perfect his arrangements. He organised four divisions at the front up the Tigris as two army corps, and from Sept. to the end of Nov. he laboured unceasingly at the base, enjoying full support from the War Office in London, which had definitely taken over charge of the campaign from the Indian authorities. By the beginning of Dec. he had been furnished with enough river craft, his supply system was sufficiently advanced, and he had the necessary war material at his command, to justify his embarking on offensive operations of a far-reaching kind, and on Dec. 13 he struck suddenly and with signal success.

Disposition of the Forces.—Von der Goltz had left Mesopotamia, and Khalil Pasha was now in command of the Turks. They had withdrawn from Es Sinn and had established an entrenched camp nearly all around Kut, while holding on to Sanniyat, and in view of their dispositions Lake had begun a railway-line to run from Shaikh Saʿad to a point near Es Sinn. It must be pointed out that Maude started his offensive with a force four times the strength of that which, under Townshend, had advanced to Ctesiphon a year earlier. His army astride of the Tigris was of necessity disposed in échelon, with its left (the II. Army Corps under Gen. Marshall) about Es Sinn, and its right (the I. Army Corps under Gen. Cobbe) facing Sanniyat. Maude's plan was to push his left yet farther forward, to clear the right bank of the Tigris to well above Kut, and, when these dispositions should in due course have taken effect, to force the lines of Sanniyat with his right.

Marshall opened the offensive by forcing the Shatt al Hai after a night march, and by capturing some of the Turkish defences which formed a bridge-head south of Kut. During the struggles that ensued, which lasted some weeks, Khalil's troops offered a stout resistance, so that although Maude's operations on the right bank of the Tigris were almost uniformly successful, they proceeded slowly and by successive stages. By the middle of Feb. the whole of the Turkish entrenched camp on that bank was in Anglo-Indian hands, and the Ottoman troops had all withdrawn to the farther side of the great river. No sooner had this part of the programme been accomplished than Cobbe on the 17th attacked Sanniyat. The effort failed for the moment; but when the assault was repeated five days later, it proved completely successful, and after a desperate contest in which the Turks lost very heavily, the formidable lines were at last carried. On the same day Marshall by a brilliant feat of arms forced a passage across the Tigris at Shumran, and no course was then left open to the Ottoman commander but to abandon Kut and retire in haste up the left bank of the river. Maude's flotilla, hitherto blocked by Sanniyat, pushed up at once past Kut, and the Anglo-Indian army could claim to have won a victory that went far towards wiping out the discomfitures of the previous year.

Turkish Retreat from Kut.—With his supplies guaranteed by the arrival of the water transport, Maude pressed on along the left bank of the Tigris on the heels of the fugitive Osmanlis. The river channel between Kut and Al ʿAziziya has many loops and bends, making it difficult for a naval force and a military force to act in concert; but on Feb. 26 the British gunboats after a smart action destroyed or captured practically the entire Turkish flotilla. Great prizes in war material and prisoners were at the same time being made by the advancing army, and the question of proceeding to Baghdad now arose. The army commander had from the outset contemplated the capture of that city after he should have expelled the enemy from Kut, and now received permission to carry out his plan. He found himself obliged to halt for some days at Al ʿAziziya, however, for fear of outrunning his supplies. On March 4 the Anglo-Indian army resumed its advance, and it was found that the Turks had fallen back behind the Diyala. This river presented a serious obstacle, and when an attempt was made to force the passage the effort proved in the first instance unsuccessful. But Maude promptly threw a bridge across the Tigris, passed the cavalry and Cobbe's corps over to the right bank, and by March 11 Baghdad was in British hands.

The Turks had withdrawn northwards, but Maude allowed no pause in the offensive to take place. Cobbe pushed up the right bank of the Tigris along which a stretch of railway ran from Baghdad as far as Samarra, heavily defeated an opposing force at Mushahida, while Marshall conducted a most successful campaign on the Shatt al 'Adhaim. Cobbe, moreover, completed the operations on the right bank of the Tigris by the capture of Samarra. Then, having secured possession of a wide area of fertile territory to the north of Baghdad and driven the enemy in confusion into the deserts and uplands beyond, Maude was at last able to afford his victorious troops rest—just as the hot weather set in.

Further Progress Northwards.—The virtual conquest of Mesopotamia in a four and a half months' campaign had been brought about by the resolute execution of a plan of operations that was based on correct calculation of requirements—by a triumph of forethought on the part of a chief who always relentlessly followed up his successes in the field. Neither the stout resistance offered by the Ottoman troops, nor the formidable defence works which they had elaborated around Kut, had in reality proved the greatest stumbling block in Maude's path. The vast extent of the theatre of war, and the fact that his army must almost inevitably adhere to the line of the Tigris, which constituted one long military defile, had interposed even greater obstacles in the way. But those obstacles had been overcome by effective preparation.

A railway was constructed from Kut to Baghdad, sanitation and policing were established in the capital, comforts and recreation were provided for the troops, and effective steps were taken to tap the supply resources of the fertile tracts that were in occupation of the army. A division that had been in reserve at An Nasiriya was brought up to the front. Great efforts were also made for a time to arrange for co-operation with the Russian forces in Persia; but the untoward influence of the revolution in Petrograd of March made itself more and more felt in that quarter as the weeks passed, and before long it became manifest that little was therefore to be hoped for in that direction. The situation in Armenia was indeed becoming such as to cause Maude some anxiety, for in the late summer it appeared that the Turks under German instigation were contemplating an effort to recover Baghdad. This made Maude the keener to resume the offensive, and on Sept. 28 he struck his first blow by the capture of Ramadi on the Euphrates. This victory was followed up by successful operations in clearing the Jabal Hamrin, and by the occupation of Tikrit on the Tigris at the beginning of November. A few days later, however, the army commander was struck down by cholera, and he died on the 10th. He was succeeded by Sir W. Marshall.

IV. OPERATIONS IN 1918

The country traversed by the Tigris above Tikrit and extending north for a long distance is a sterile tract, hilly and broken at some points; the ordinary route from Baghdad to Mosul does not therefore follow the river but takes a direction to the east through Kifri and Kirkuk.

Maude's Plan.—Maude had intended to conduct his main advance by this line, but his death just at the moment when the project was to be put in execution created some delay; his successor, however, set troops in motion through the Jabal Hamrin in Dec., and by these Kifri was occupied in Jan. 1918. Having secured that point, Marshall suddenly set his extreme left wing on the Euphrates in motion in the middle of Feb., with the result that Hit was captured and the Turkish division which had retired up the river was surrounded, 5,000 prisoners and all its guns being taken. Transport difficulties were hampering the advance beyond Kifri on the other flank, but on April 29 the Ottoman forces were heavily defeated on the road to Kirkuk, losing 3,000 prisoners, and a week later Kirkuk was taken. Marshall, however, decided to withdraw his advanced troops in this
quarter to Kifri, and active operations then practically ceas
for five months. The collapse of Russian fighting power in A
menia had enabled the Ottoman staff to move some troops fro
there down to Mosul and northern Mesopotamia, and scarce
any assistance had been received from Persia; but Marshal
first campaign had nevertheless been remarkably successful a
his position to the north and north-west of Baghdad had be
effectually consolidated.

The British Mission to Persia.—In the meantime a spec
British mission, sent off in Jan. under charge of Gen. Dunst
ville, and originally intended to proceed to Tiflis with the obj
of co-ordinating the resistance of the Armenians, Georgians a
Russians to the Turks threatening Transcaucasia, had be
trying to maintain satisfactory relations with the Russians
Persia. But great difficulties were placed in Dunsterville's w
by the Russian officials, who were tending towards Bolshevis
while open hostility was displayed by certain of the Persi
tribesmen. Some Russian troops, however, remained loyal
the Entente, and co-operating with these, small bodies of Briti
troops were gradually pushed north so as to establish a line
communications between the Anglo-Indian army in Mesop
tamia and the Caspian Sea at Enzeli. Resistance to the Tur
in Transcaucasia was gradually breaking down during the ea
summer, and at the beginning of July the last of the Russi
detachments in Persia proceeded thither by ship. The Ottom
troops appeared before Baku shortly afterwards and Dunst
ville with a brigade of infantry therefore sailed for that city
August.

He found the Armenian garrison to be unreliable and the at
tude of the Russian officials to be suspicious. The lines constru
ed for the defence of the place were of such extent as to requ
a large force to man them, Bolshevik armed craft afloat on t
Caspian were a source of danger, and it soon became appare
that the safety of Baku depended entirely upon the meag
British force that had been thrust into it, for the Armeni
soldiery displayed but little stomach for combat. Dunstervi
and his men did what they could to save the place for a few wee
but on Sept. 14 the Turks broke through the outer defences, a
that night the British re-embarked and returned to Enz
whereupon Baku passed into the enemy's hands. A somew
hazardous venture had failed; but it had at least prevented t
dispatch of some of the Ottoman troops in Transcaucasia
confront the Anglo-Indian army in northern Mesopotamia.

Closing Stages of the Campaign.—The fall of Baku occur
just when the season had again become suitable for active ope
tions on and about the Tigris, and Marshall was now direct
to occupy Mosul, an undertaking for which he had been prep
ing all the summer. The best of the Turkish divisions were
this time assembled astride of the Tigris at Al Fat-ha, the poi
where the river breaks through the Jabal Hamrin range of hi
Here a naturally formidable position had been strongly fortifi
and another position a few miles higher up the river had likew
been prepared for defence. Realising that a frontal attack wou
be hazardous and that a tactical turning movement was vir
ally out of the question, Marshall decided to throw an adequ
force across the Ottoman communications between Al Fat-
and Mosul. He entrusted the conduct of the operations as
whole to Gen. Cobbe, and arranged for a column to adva
simultaneously from Kifri by Kirkuk towards Mosul.

Surrender of Ismail Hakki.—The final campaign in Mesopo
mia began on Oct. 23 and it lasted only one week. Two caval
columns, that with the shorter distance to cover being acco
panied by some infantry, crossed the Jabal Hamrin many mi
to the east of Al Fat-ha, passed the Little Zab a long way abo
its junction with the Tigris, and hit off that river several miles
the rear of the Turkish positions at and above Al Fat-ha.
the meantime the 17th Div. operating on the right bank and t
18th Div. operating on the left bank of the Tigris moved forwa
from above Tikrit. Finding himself threatened by the caval
forces which were approaching the river between him and Mos
Ismail Hakki Pasha, who commanded the Turks, now withdr
from the Al Fat-ha position to the one higher up at the co

ience of the Little Zab, followed up by the two Anglo-Indian
visions. But the 18th Div. advancing on the left bank of the
gris, forced a passage across the Little Zab on the 25th, thus
rning Ismail Hakki's left flank, and the Pasha thereupon trans-
rred those of his troops that were on that side of the Tigris
ross the river and broke up his bridge.

On the 27th the 17th Div. was pressing the Turks, who were
w all collected on the left bank of the river, and on the same
y one of the cavalry columns forded the stream and began
oving down that side of the channel against the enemy's rear.
e 17th Div. was heavily engaged on the 28th before it finally
ade itself master of Ismail Hakki's position at the confluence
the Little Zab. That commander thereupon retreated to Shar-
t, but on the morrow the last hope of the trapped Turkish
ce was destroyed, when a relieving column that was approach-
; from Mosul was defeated by Cobbe's cavalry. All that day
nail Hakki resisted the advance of the Anglo-Indian forces on
arqat. On the morning of Oct. 30, however, just as the 17th
v. was about to launch a final attack, the white flag was dis-
yed within the Turkish lines, and the whole of one Ottoman
ision, together with the bulk of another one, surrendered,
000 prisoners, 51 guns and imposing stores of war material
ing into the victor's hands.

The Kirkuk column had in the meantime been steadily work-
its way forward towards Mosul, almost unopposed, and
bbe's forces were about to advance on the city from about
arqat, when tidings came to hand of the signing of the
nistice. Mosul was occupied a week later, but the Otto-
n power of resistance in this theatre of war was in any case
ttered as a result of Marshall's final blow. Thus the long
wn-out struggle in Mesopotamia, which had proved so con-
ently favourable to the Anglo-Indian arms since Maude had
nched his offensive at the close of 1916, ended in a blaze of
mph two years later, concurrently with what constituted the
st sweeping tactical success that had been gained by either
e during the course of the campaign.

IEŠTROVIĆ, IVAN (1883–), Yugoslav sculptor, was born
'rpolje in Slavonia, the son of Croatian peasants. The rudi-
nts of his art were taught him by his father and at the age
3 he was apprenticed to a marble cutter at Split (Spalato),
three years later entered the Vienna Academy where he
died under Hellmer until 1904. During the succeeding years
exhibited at the Vienna Secession, at the Austrian Exhibi-
at Earl's Court, London (1906), at Munich, Venice and
is—where he attracted the notice of Rodin. He was largely
onsible for the formation of a nationalist artistic movement
ch included the sculptors Rosandić and Dujan Penić, the
ter Rački and the architect Plečnik, and which culminated
he exhibition at Zagreb in 1910 and the Rome international
bition of the following year. His work at this period centred
fly around a projected Temple at Kosovo, for which he
e a model for the building and a large number of figures of
oslav heroes—Marko Kraljević, Miloš Obilić, Banović Stra-
a and Srdj—caryatid figures and groups and single figures
nourning widows. In 1915 an exhibition of his sculpture
held at the Victoria and Albert Museum, London.

esides the naturalistic works designed for the Temple,
trović made a large number of religious reliefs and figures
alnut, of which two Pietà reliefs, one in the National Gallery
ritish Art and one in private possession, are typical of his
cutting and great powers of design. His portraits include
e of his mother (1908), Madame Banac (1913 and 1915),
wife (1915), Sir Thomas Beecham (1915, in the National
ery of British Art), Lady Cunard (1915) and Miss St.
rge (1915). Among his later works the most important are
richly decorated Raćić Memorial Chapel at Cavtat, near
Dubrovnik (Ragusa), Dalmatia (1920–2), the designs for the projected mausoleum of Bishop Petar Petrović Njegoš, the Montenegrin poet, to be erected on the summit of Mount Lovćen (1924), and figures of St. Francis of Assisi and "The Artist's Mother in Prayer" (1925). In 1924 exhibitions of his work were held at the Fine Art Society in London and the Brooklyn Museum.

See M. Curčin, *Ivan Meštrović, a Monograph*, with bibliography and list of works (1919). For details of the Raćić Chapel, see *Deutsche Kunst und Dekoration*, LII. (1923).

METALLOGRAPHY (*see* 18.2b).—Metallography is the study of the internal structure of metals and alloys, and of its relation to their composition and their physical and mechanical properties. Beginning with the use of the microscope for the examination of polished and etched surfaces of metals by Sorby in 1864, the scope of metallography has been widened to include other methods for the examination of the internal constitution of solids, such as the measurement of changes of volume and of heat content, and of electrical resistance, magnetic quality or behaviour towards X-rays.

The properties of metals and alloys, like those of other solids, depend partly on their chemical composition and partly on the internal arrangement of their constituents. It is possible for two specimens of metal, taken from the same homogeneous mass and identical in chemical composition, to have widely differing properties if they have been subjected to different thermal or mechanical treatments. Since this important fact has become generally recognised, other methods of examination must supplement chemical analysis in the control of materials for engineering and similar purposes, and in recent years there has been a great development of metallographic methods, together with a greatly increased application of them in industry, so that the microscope has become as indispensable as the balance in metallurgical works, whilst dilatometers, magnetic and electrical measuring instruments, and accurate pyrometers are becoming more and more frequent items of the equipment of a laboratory for the control of materials by manufacturers or users.

Preparation of Specimens.—The improved microscopical technique of the present day, and the use of high magnifications, make it necessary to prepare the surfaces of specimens with a very perfect polish. Polishing by hand on fine emery papers is preferred to the use of a machine, except in the last stage, when a rotating disc covered with cloth is used, the finest polish being given by levigated magnesia, although for low magnifications alumina is quite satisfactory. Steels are best etched by a 4% solution of picric acid in alcohol to which a small quantity of nitric acid may be added to bring out the boundaries of the crystal grains. Stainless steel and other highly alloyed steels require special reagents. Many tables are now published giving the most suitable reagents for the etching of the commonly occurring metals and alloys. Much light has been thrown on questions of metallurgical importance by the use of high magnifications, and progress is being made in this direction. It is important to observe the conditions of accurate microscopy by making a suitable choice of objective and eyepiece for the work. Mere magnification without higher resolution gives no information of value. The internal structure of martensite in hardened steel is a severe test of the resolving power of a microscope, and has been studied in detail with some success. The inverted type of microscope, in which the specimen is placed with its polished face downwards on the stage, has many advantages in convenience and rapid working, and has become popular in metallographic laboratories, in spite of certain optical disadvantages due to the larger number of reflections.

Macroscopic Etching.—In another direction, the examination of etched specimens with little or no magnification has proved of great practical value. For this macroscopic etching the surface to be examined is roughly polished and then deeply etched, acid solutions of copper salts being mostly used for steels, the copper which is deposited at first being completely removed by washing. Segregation is revealed by differences of etching, a very distinct pattern being produced, which may be recorded by photography or by the method employed long ago by Sorby in making "nature prints," and temporarily forgotten, of using the etched surface as a printing block, rubbing printer's ink into the depressions, and transferring to paper by pressure. Macroscopic etching has proved of value in the detection of defects in ingots and castings, and also in following out the treatment of a metal during such processes as forging, the direction of the flow during working being shown by the curving of the lines representing small differences in composition in the original mass. This method is employed in some works as a regular means of control in the forge.

Strain Etching.—In 1921 a method of etching was described by A. Fry, having as its object the detection of plastic strain in mild steel. The steel to be examined is polished, care being taken to avoid any distortion, and is then annealed for a short time at about 200°C., after which it is etched in an acid solution of cupric chloride. Clearly defined dark bands make their appearance where the crystals have been deformed, and much information as to the distribution of plastic movement is obtained from a study of the figures. Rather strangely, whilst some mild steels give well defined patterns with ease, others of almost identical composition give no result, and it has not been possible to trace any connection between the composition and the degree of success of the etching. The method has therefore so far a limited value, but it is almost certainly capable of further development. On a microscopic scale, the mechanism of deformation has been studied by many investigators. Metals and alloys vary greatly in the degree of apparent confusion in the crystalline structure produced by deformation. Cupro-nickel is remarkable for its property of undergoing severe cold-working and continuing to give perfectly sharp and definite structures when etched, and this alloy, together with pure aluminium and an alloy consisting of tin to which 1·5% of antimony has been added, have been largely used in the study of the cold-working of metals and of the microscopic changes which occur on subsequent annealing.

Plastic Deformations.—The nature of plastic deformation being of such great importance to the engineer, this part of the subject has attracted much attention. A mass of metal, such as a forging, consists of an immense number of crystalline grains, the axes of which are directed at random, so that for practical purposes the metal is commonly regarded as isotropic, the individual differences being lost in the aggregate. At the bounding surfaces of the grains there is a discontinuity of properties, the origin of which is a subject of controversy. The failure of metals by fatigue (*see* FATIGUE OF METALS) under rapidly alternating stresses, cannot be explained by any assumption of isotropic character, and it becomes necessary to take into account the stresses in the individual grains. The problem is simplified by the comparatively recent discovery of methods for the preparation of single metallic crystals of such large size that they may be tested in an ordinary testing machine, the microscopic and other changes being observed. Aluminium has been studied in detail in this way by Carpenter and Elam; tungsten (in the form of wire) by Goucher and zinc, tin and bismuth by Polanyi and Weissenberg. In these instances the direction of slip and its relation to the crystalline structure have been determined.

The influence of the crystal boundary is studied by using test pieces composed of two crystal grains, a boundary crossing the specimen. Beyond the fact that the boundary offers an obstacle to slip, little has yet been established in regard to this factor, although the hypothesis of a layer of amorphous material between the grains has been applied with great ingenuity and success by Rosenhain to explain many of the facts of deformation and also of chemical attack on metals. The low tensile strength of metals, as compared with the theoretical cohesion calculated by indirect means, has led to the suggestion by A. A. Griffith that all ordinary solids contain innumerable minute flaws, and this hypothesis has attracted the attention of mathematical physicists, who have applied it with some success. By special devices, vitreous silica and glass have been prepared in an unstable condition in which the strength is of the order of the theoretical cohesion, but this has not been attained with metals.

X-ray Analysis.—Some departments of metallography h
been transformed by the introduction of the methods of X-
(*see* X-RAYS) analysis. The use of X-rays for the penetratio
large masses of metal for the detection of blowholes and ot
defects is obvious, and whilst useful in practice has no theoret
significance; but the refined methods of crystal analysis due
Laue and to Bragg are far-reaching in their effects. The arran
ments of the atoms in a space lattice (*see* CRYSTALLOGRAP
and the absolute dimensions of that lattice have now been de
mined for most of the important metals, and many interest
results have been obtained, amongst others the fact, establis
by Westgren, that α and β iron below 900° C. and δ iron ab
1,410° C. have the same space lattice, a body-centred cube, wh
γ iron between 900° C. and 1,410° C. has a face-centred cubic
tice, and this conclusion is in harmony with the physical pro
ties of these modifications of iron. The same method provi
an accurate determination of the direction of slip in single c
tals during straining, whilst the examination of drawn wires
of rolled sheets has shown that there is a tilting of the sp
lattices of the individual crystal grains, leading to a more or
parallel direction of one of the crystal axes throughout,
"fibre structure" being similar to that which the X-rays
show to be present in natural fibres. Studies of this kind
throwing much light on the question of the mechanical stren
of materials.

Thermal Analysis.—The methods of thermal analysis h
undergone comparatively little change. To ensure a unif
rate of cooling, the specimen of metal may be suspended i
furnace in which a steady temperature gradient has been est
lished by winding a metal tube with resistance wire suitably i
lated, and making the windings closer at the upper part.
specimen is then lowered through the furnace at a uniform
by a mechanical device. It has been shown that the speci
should have a spherical or pear-shaped form in order to ob
sharply defined points on the heating and cooling curves. T
mo-couples are almost invariably used for the measuremen
temperature, although the platinum resistance thermome
used in the early and extremely accurate work of Heycock
Neville, has great advantages. Japanese workers, investiga
the alloys of iron, have made much use of magnetic determ
tions as a means of fixing temperatures of transformation,
curves having much the same form as those derived from t
mal observations; whilst other investigators have used
changes in electrical resistance with temperature for the s
purpose. Several types of dilatometer have also been devi
in which the changes of length of a rod of the metal or alloy
ing heating and cooling are measured directly or by compar
with a standard or with a rod of vitreous silica with neglig
expansion. Where the change of length is indicated by the
ing of a mirror, this method is susceptible of very great accur
It has proved of value in the study of hardened steels, an
now making its way from the research laboratory into techn
practice.

Practical Applications.—The higher standards of strength
endurance demanded of metallurgical products by the mod
motor and aeroplane industries (*see* AERO-ENGINES) and by
other branches of engineering as the manufacture of st
turbines (*q.v.*), have been responsible for the interest now b
taken by engineers as well as by metallurgists in the stud
metallography. Alloy steels, and many of the higher qual
of plain carbon steels and of non-ferrous alloys, have to be "h
treated" to develop their maximum toughness or other desi
properties. To determine whether the treatment has bee
correct one the methods of the metallographic laboratory
be applied. Moreover, the engineer is concerned with such p
lems as that of fatigue (*see* FATIGUE OF METALS), and with
general nature of mechanical deformation beyond the limit
which the theory of elasticity is applicable.

The methods devised for the study of metallic alloys
proved to be of value in the scientific examination of other so
Whilst the original idea of the examination of metals by m
of the microscope occurred to Sorby in consequence of his ea

roduction of microscopical petrography, the technique of tallography has been applied to opaque minerals, and has de possible the detailed study of mineral veins and ore de- sits. The work of the Geophysical Laboratory at Washington the equilibrium in rock magmas (*see* PETROLOGY), with its thods of accurate measurement at high temperatures, is also sed to a great extent on experience gained in the study of tallic systems.

BIBLIOGRAPHY.—The most comprehensive treatise is that of Guertler, *Metallographie*, Berlin, in course of publication since 9, and extending to many volumes. Other text-books are: Guillet and A. Portevin, *An Introduction to the Study of tallography and Macrography* (Eng. trans., 1922); E. Heym, *ysical Metallography* (Eng. trans., 1925); G. Tammann, *A Text- k of Metallography* (Eng. trans., New York, 1925); C. H. Desch, *tallography* (1922). On plastic deformation, Z. Jeffries and R. S. her, *The Science of Metals* (New York, 1924); G. Sachs, *Grund- riffe der mechanischen Technologie der Metalle* (Leipzig, 1925); G. Beilby, *Aggregation and Flow of Solids* (1921). On X-ray lysis: W. H. and W. L. Bragg, *X-rays and Crystal Structure* 24); R. W. G. Wyckoff, *The Structure of Crystals* (New York, 4); whilst papers on metallography are to be found in many rnals. The principal sources are the *Journal of the Iron and Steel titute, Journal of the Institute of Metals, Zeitschrift für Metall- de*, and *Revue de Métallurgie*, all of which include abstracts and liographies as well as original communications. *The Mitteilungen dem Kaiser-Wilhelm Institut für Eisenforschung* contain many ortant papers. For the practical applications see also the *nsactions of the American Society for Steel Treating*. (C. H. D.)

IETALLURGY (*see* 18.203).—Progress in metallurgy after I was profoundly affected by the World War. Modern war- e is so entirely dependent upon the products of metallurgy t the effort to secure military victory to some extent resolved lf into a struggle for supremacy in metallurgical output, in ard to steel products such as guns and shells, ship-plates and our, etc., to copper and its alloys, to zinc, to lead and anti- ny, and, in a special degree, to aluminium.

uring the war period, therefore, the progress of metallurgy ame mainly a relentless struggle for output in which, in some ctions, quality was sacrificed and heavy "war risks" were erfully taken. After the termination of the War, industrial con- ons became extremely unsettled and difficult; the shortage of s was followed by acute industrial disturbances, particularly in land. The Continental nations only slowly resumed their normal vities, and were gravely hindered on all sides by the direct and rect economic consequences of the Treaty of Versailles. As the lt of continued political and financial uncertainty, recovery in metallurgical industries remained slow, except perhaps in gium, until 1925. Towards the end of that year, following the roved atmosphere resulting from the Locarno Pact, signs of im- vement began to set in. Meanwhile, however, the metallurgical stries of America experienced a period of special prosperity, and relative rate of development in metallurgical practice in the tern and Western hemispheres must be in part ascribed to these ors.

DIVISIONS OF THE SUBJECT

he whole period under review thus falls into three main divisions: r to 1914, the War period and the post-War period. The influ- e of the War has left important traces in certain directions but line of development appears to be tending towards a simple inuation of pre-War lines. Thus, very great efforts in England in certain of the British Dominions to render those countries allurgically self-supporting were made either as the result of ct governmental encouragement and support or on account of abnormally high prices ruling for some of the metals. This led he development of properties and processes which were, under e normal conditions, uneconomical, and these—with govern- tal support unavoidably withdrawn and prices at a less abnor- level, have necessarily been abandoned. An important exception e great development in the zinc industry in Great Britain and tralia, in which, thanks to real metallurgical advances, permanent omic success has been achieved.

a totally different direction, however, war conditions led to a xation of the severity of specifications, particularly for steel lucts.

fter the War, steel makers claimed that their difficulties were ost as great as ever. It was suggested that the relaxed specifica- s had led to no disastrous results and that, therefore, they might afely continued. The British Engineering Standards Associa- adopted a compromise course and, while rejecting the extreme xations accepted under War conditions, also refrained from a rn to full pre-War severity. It has resulted that "War time lucts" are looked upon with grave suspicion. A steady tendency ards increasing stringency in specifications, particularly in the direction of higher requirements as to the purity of metals and alloys, is now (1926) making itself felt. A similar tendency appears to exist also in America, but the methods of applying specifications and tests in that country are so widely different from those adopted in England that direct comparison is liable to be misleading.

Another effect of the War, and of the subsequent strong movement towards disarmament, has been the need for industrial rearrangements and reconstructions on a large scale. At the end of 1918, the metallurgical and allied industries were entirely devoted to armament and munitions and had then to find different outlets for their activities. The engineering reconstruction work required in the devastated regions of Europe proved no adequate outlet and in many cases, particularly in England, great works had to close down. In America, with an enormous home market the conversion of armament and munition works to peaceful output was carried through successfully on a large scale. Consequently, the industrial "slump" in that country was comparatively slight and brief.

I. IRON AND STEEL

Prior to 1914 iron and steel metallurgy showed a tendency towards the development of very large plants and larger individual units, both in regard to furnaces and rolling-mills. The tendency towards increased size made itself felt in the blast furnace, particularly in American practice; progress, however, also included development in the direction of furnaces with walls and external water-cooling, such furnaces being driven very hard.

Pre-War Progress.—In the period prior to 1914, considerable attention was given to drying the blast, and it seemed at one time that this would become universal practice. Under war conditions this development was checked, at all events in England, and has not been resumed since 1918.

Increased attention has, however, been given to the utilisation and cleaning of blast furnace gases. This became particularly important in England during the War on account of the shortage of potash, a substantial recovery of this material being obtainable from the flue-gases of furnaces in which the charge included potash-felspar. At the same time satisfactory cleaning of the gas very much increases its efficiency in stoves and under boilers, owing to the absence of fouling with dust. On the other hand, a degree of cleaning which will render the gas fit for direct use in gas-engines is a much more expensive matter, and not so obviously economical. The cleaning processes adopted are mainly of two kinds; one of these depends upon the electrostatic deposition of the dust by the method first suggested by Lodge and developed in America by Cottrell (*see* FUME PRECIPITATION). The other method depends upon filtration of the gas through fabric bags which are kept in a state of agitation, as in the Halberg-Beth system. Although, under normal conditions, potash recovered from flue-dust could not compete with the product of Continental mines, yet cleaning of blast-furnace gas will be continued. The dust itself may be utilised for the recovery of iron contained in it, by briqueting the dust by a modification of the Schumacher process, in which a weak solution of ferrous sulphate is used as binder. A further proposal is to concentrate the iron-content by some adaptation of the flotation process.

The application of flotation processes (see below) to finely divided iron-ores had not been found necessary or practicable up to 1926, but methods dealing with finely divided ores (both ferrous and non-ferrous) have been considerably developed. In addition to the Schumacher process already mentioned, reference must be made to the Dwight-Lloyd process, in which the ore is mixed with a small proportion of finely divided carbon and pressed into briquettes which are then heated to a moderate temperature. A partial reduction of the ore takes place, leading to a sintering of the briquette which thus acquires the necessary strength.

In the production of steel, the open-hearth furnace has made very great progress and appears likely to displace the Bessemer converter, although the latter seems to be holding its own to a certain extent. The steady increase in the application of basic open-hearth steel tends to give the large open-hearth furnace, particularly when working one of the continuous processes, a very great advantage.

War Period.—In the first place it became necessary, particularly in England, to make use of ores and other materials very different from those for which particular furnace plants had been designed, while the supply of operative labour became very difficult. In consequence of these and other difficulties, relaxation of quality, already mentioned above, became inevitable, particularly in regard to those grades of steel which were required in very large quantities.

Apart from the demand for enormous supplies of steels of ordinary grades, War conditions also caused great demands for steels of the highest quality for special purposes. The production of guns was one of these, and much difficulty was encountered both in England and America with defects—known as "snow flakes" or "gun measles"—occurring particularly in nickel-chrome steels. Reversion to the use of a simple nickel-steel for such purposes followed, but this entailed a serious disadvantage, if only on account of the greater difficulty experienced in securing satisfactory heat-treatment. This difficulty was also encountered in connection with the gearing used for the propelling machinery of turbine-driven ships. High-quality steels, mainly alloy steels, were also required in relatively very large quantities for purposes of air-craft construction, principally for the working parts of aero-engines. This demand led to a great development in the production and treatment of alloy steels.

Here, and generally in the production of the better grades of steel, the electric furnace played a remarkable part. A large number of furnaces, mostly of the arc-resistance type, were installed, particularly in Sheffield. Their value lay in the super-refining of steel, sometimes produced in a basic open-hearth furnace, sometimes obtained by the direct remelting of alloy-steel scrap. Probably the power of the electric steel furnace to deal satisfactorily with such scrap, even when in the form of workshop swarf, constituted its greatest value during the War. Since the end of the War, however, the demand for such steel has almost disappeared, with the result that the greater number of the electric furnaces, both in England and America, became idle. None the less, there must be, in the future, a definite use for a certain number of electric furnaces in steel metallurgy.

Alloy Steels.—In regard to alloy steels, while nickel-chrome and nickel steels have found by far the widest application, particularly for war purposes, other alloy steels have also assumed importance.

Nickel-chrome steel in particular, in addition to the difficulties already mentioned, has been found to be subject to a defect known as "temper brittleness." Alloy steels, in order to assume their most desirable physical condition, require specific heat-treatment, which, as a rule, consists of quenching in oil, or more rarely in water, from a temperature above the critical range of the steel, followed by "tempering" or reheating to a temperature considerably below the critical range. In the majority of steels, the rate of cooling subsequent to tempering is of little importance, but in a certain number of nickel-chrome steels slow cooling after tempering leads to a form of brittleness which is entirely removed if the steel is cooled very rapidly (quenched) after tempering. The cause of temper-brittleness has received much investigation, and the results indicate that it is due to a change or "transformation" which occurs in the steel at or near 300° C.; it appears to be favoured by certain impurities, notably phosphorus.

Further, acute controversy has arisen as to the importance or otherwise of such "temper brittleness" on the ground that it can only be detected by a particular form of test—the "notched bar impact test." Hatfield has repeatedly suggested that this test measures a property of no practical importance, and that therefore temper brittleness is only "apparent" and not "real." This view, however, has not been generally accepted, since a number of investigators (Rosenhain, Greaves and others) have found a very distinct correlation between a low value under the notched bar impact test and cases of actual failure in service.

Chromium Steels.—For certain purposes, where simple nickel steels are not found adequate, a chrome-vanadium steel has been extensively used. The fact that vanadium plays a really important rôle in such steels has come to be recognised, but there are still difficulties in its metallurgical applications. For quite a different range of purposes a steel containing relatively large amounts of chromium (about 13%, Brearley) has found wide applications. Its best-known application is to the production of "stainless" cutlery, which has proved extremely successful in practice, and in spite of the relatively high cost has come into extensive use as a labour-saving device (*see* RUSTLESS STEEL). Some difficulty was at first experienced in hardening this material satisfactorily; it requires a higher quenching temperature than cutlery-hardeners have been accustomed to employ (Hatfield), and, as a consequence, the earlier products were insufficiently hardened, and gave rise to the complaint that such cutlery would not keep its edge. Later practice has overcome this defect, although the fact still remains that "stainless" knives, not being automatically sharpened by daily polishing, req careful sharpening from time to time.

New applications of this steel to other purposes where res ance to corrosion is important are being found almost da Incidentally, it was found that this steel is capable of resisting severe conditions which occur in the service of an exhaust-va in aeroplane engines, although a high-tungsten steel (1 tungsten) has been found to be slightly better. More recen special alloy steels for use at high temperatures have been veloped both in England and in Germany. These contain c siderable proportions of both nickel and chromium, while some cases tungsten is also present. Unlike the simple chromi steels, these new materials retain a considerable degree strength at temperatures well above 700° C., particularly tested in tension at ordinary rates of loading. Testing un prolonged loading—known as "creep stress testing"— however, been developed to furnish more reliable data wh material is exposed to continued load at high temperatures, it is as yet difficult to find any material which shows a hig "creep stress" than two tons per sq. in. at 800° Centigra This figure is attained both by some of the steels just mentio and by a non-ferrous nickel-chromium alloy (80% nickel, 2 chromium). This whole subject is attracting much attentio view of the tendency towards the use of higher temperatures pressures in both steam and internal combustion engines.

While the simple chromium steels of the "stainless" type hold the field for cutlery and similar purposes where hardnes essential, their powers of resisting corrosion have been surpasse a surprising degree by the recently developed alloy steels contai considerable proportions of both nickel and chromium, with, h ever, very little carbon. These are "austenitic" steels, *i.e.*, t consist mainly of what is known as "gamma" iron, are n magnetic and very tough and ductile. They cannot, however hardened by quenching, although they frequently exhibit a tende to harden very markedly under the action of cold working. manganese steel of Sir Robert Hadfield, which proved so valua as a material for shrapnel-proof helmets during the War, is extreme example of this kind, as this steel becomes intensely h when subjected to cold working, even if this only takes the form surface abrasion. The high nickel-chromium steels do not harde anything like the same extent, but sufficiently so to make th difficult to machine.

Like manganese steel in the quenched or "toughened" condit they are non-magnetic, but their outstanding feature is resistanc corrosion. The best of them remain unaffected by most liquids, cluding sea-water, solutions of magnesium chloride and even str nitric acid. Strong hydrochloric acid alone attacks them. Th remarkable materials have only recently (1925) become c mercially available, but their application is already develop rapidly. Their good physical properties, combining high stren and great ductility, make them desirable materials for many kind structural work, but applications on the very large scale are hindered by their relatively high cost.

High-speed Steels.—In the metallurgical progress of the per under review, the development of high-speed cutting st occupied an important place, their possibilities having b steadily exploited to an increasing extent, their developm being naturally accompanied by an evolution of machine-t capable of utilising the high cutting powers of the new ste Under war conditions the great demand for tool-steels of kind created a relatively enormous demand for tungsten, considerable developments in the mining and production tungsten took place. Efforts to replace tungsten by other me were also made, and very great claims were advanced for a hi speed steel in which molybdenum in combination with vanadi was used in place of tungsten (Arnold). The action of cutt tools has received careful study by a number of investigat largely under the auspices of the Cutting Tools Research C mittee of the Institution of Mechanical Engineers.

In connection with high-speed steels, mention may here be m of a type of alloy which has been used, with considerable success place of such steel. This, known as "stellite," consists, accordin a reliable analysis, mainly of cobalt 56%, chromium 34%, tungs 9%, carbon 1%. Tests with this material have shown that capable of cutting rather faster than the best tungsten steel, vided that the cut is smooth and regular, but that for roughing c where the tool is subjected to sudden shocks and jars, the allo unsuited, as it is too brittle and the tool frequently breaks ese alloys, originating in America, have received much attention l development in Germany. In England the hardness and in- rodibility of these alloys has led to their use as a substitute for tinum for such purposes as standard weights.

Cobalt Steel.—The great development of cobalt production at dbury in Canada has made this metal available and has at- cted interest to its possible uses. A high-speed tool-steel, taining cobalt has been produced in Sheffield, which has been ccessful in general use and has the remarkable property that it es not undergo distortion during hardening. Great difficulty sted under war conditions in the production of accurate parts uch as those of shells and fuses—which were required to be ictly interchangeable. This difficulty extended back to the ges and master-gauges used for the checking of such parts l ultimately in many cases to the cutting-tools used in their duction. In other cases, the steel of which the gauges them- ves were made gave much trouble owing to distortion during rdening, requiring considerable adjustment by " lapping " of hardened article.

A cobalt steel has also become important for permanent gnets. Made in the first place of hardened carbon steels, the uirements particularly for the magnetos used for ignition pur- es in aircraft engines led to the use of special steels containing ut 6% of tungsten. A Japanese invention, based upon ex- sive researches carried out in that country (Hondo), has duced a cobalt magnet steel which, in its best examples, gives prising results, combining an exceptionally high coercive force h a relatively large remanence. By the use of this steel a ch smaller and lighter magnet suffices for a magneto of given ver. The steel is expensive, and when supplied in quantity pears to vary in quality, while there is also some difficulty in workshop manipulation.

Case Hardening.—Processes for the surface hardening of tough l have come into increasing use, and methods for securing hardness of the case, with a tough core and good gradation ween the two, have been developed. More recently a method urface hardening has been worked out in Germany (Krupp) ch entirely avoids the necessity for quenching and its attend- distortion. A special steel, containing both chromium and minium, is employed, and the surface is hardened by the mation of a layer of intensely hard nitride, produced by pro- ged heating at about 500° C. in a gas consisting mainly of monia.

Welding.—One of the most remarkable developments (metal- gical in the wider sense) during the period under review has n that of autogenous welding, (*q.v.*) both by the oxyacetylene ne and by the electric arc.

oth these processes afford a relatively cheap and simple means of king joints in metal, particularly in iron and steel, and as the joint sists of " the same metal " as that which is being joined there is a cious suggestion that the joint is " perfect " in the sense of being ood as the unjointed material.

lthough it is quite possible to obtain welded test-pieces which ak, under a tensile test, away from the actual joint, the joint lf can never be regarded as equal in strength and toughness to unjointed steel. The reasons are that the material in the weld lf has solidified from fusion and is at best equal in properties to same steel in the cast condition, while the rest of the plate itself been immensely improved in quality by forging and rolling and sibly by heat-treatment. Further, adjacent to every such weld e is a region of steel which has either been severely overheated or little farther away—which has been heated to a temperature just w the critical range. In both these regions the steel is seriously kened, and it is in the latter that test-pieces generally break.

he most serious difficulty, however, is that of being sure that any ogenous weld is truly sound. Examination of many welds has wn that complete soundness is difficult to secure, and that it is exception rather than the rule, even in careful practice. Also, it ot possible to ascertain by any external examination of a weld ther it is sound or not. Examination by the aid of a powerful ay installation can sometimes be employed to assure the sound- of an important weld, but as a rule this is not feasible. It ld seem, therefore, that there is grave doubt whether welded ts can be relied upon to carry severe working stresses or whether should be employed in vital parts unless an exceptionally heavy or of safety can be allowed.

xperience in aeroplane construction supports these doubts, and a struction in which steel tubes are joined together by pinned and soft-soldered joints has been found more reliable than autogenous welding, provided that the working stress on the solder is kept to a low value. On the other hand, the welding processes afford a ready means of making joints and effecting repairs where no other process could be used, and under war conditions particularly rapid repairs were frequently executed with great success. At the same time, welded joints should not be compared with the unjointed material but rather with joints made in other ways, such as riveting; and there the comparison is much more favourable except for the serious element of uncertainty. The application of welding, and particularly of electric arc welding, to such purposes as ship construction, has, however, found considerable acceptance.

Cast Iron.—This metal has received much attention, both on the practical and the research sides. In Germany this is strongly indicated by numerous patents and scientific papers and in Great Britain by the formation and growth of the Cast Iron Research Association. One of the most striking developments is that of so-called " Pearlite " iron, in which the rate of solidification is adjusted, by suitable preheating of the sand moulds, to the thickness of the casting and the silicon content in such a way as to secure desirable (pearlitic) microstructure and specially good physical properties. Special furnaces suitable for the production of cast irons low in total carbon, or specially desulphurised, have also been developed.

In America the production of malleable castings on a large scale has progressed, with the introduction of electric furnace melting for the iron and malleable-annealing in continuous furnaces of the tunnel-kiln type. The casting of grey iron castings in permanent metal moulds has also been developed, the chilling effect of the iron mould being avoided by the interposition of a hard layer of relatively non-conducting refractory material. The exposure of cast-iron to increasingly high temperatures has revived the problem of the " growth " of this metal, particularly on repeated heating and under the influence of superheated steam. The view that growth is essentially due to oxidation occurring in the graphitic pores of the iron is still held, but it is recognised that this action is not solely due to silicon and that it may be as much dependent upon the treatment of the iron and its consequent structure as upon its chemical composition.

II. NON-FERROUS METALS

Flotation Process.—The outstanding feature in the progress of non-ferrous metallurgy is summed up in the one word " flotation." Published scientific research (Langmuir, Sulman and Picard, Edser) has gone far towards the explanation of this process which has made enormous progress and has revolutionised the practice of the extraction of many non-ferrous metals, particularly those occurring in the form of sulphide minerals, such as galena, zinc-blende and the various pyritic copper ores. Its effects have been direct in superseding most gravitational methods of separation, and indirect in view of the fact that flotation deals primarily with very finely divided material, including the " slimes " which were the greatest difficulty of the pre-flotation metallurgist. Not only has this affected ore-grinding and handling practice, but it has brought about a great change in smelting practice also. Thus the treatment of copper concentrates is being carried out to a rapidly increasing extent in the reverberatory furnace to the steady exclusion of the blast furnace.

The Principles of the Process.—The principles of flotation do not appear to be entirely understood, as there is considerable divergence of opinion whether flotation phenomena are the result of purely " surface tension " forces or whether electrical forces play the most important part. The operations involved are, however, sufficiently clearly defined and consist essentially of three steps which may overlap or merge into one another. The first of these may be described as the " oiling " process, which consists in adding to the pulp or mixture of finely ground ore and water some " oiling " reagent. This may be either an essential oil or one of a great range of chemical substances, generally organic in character. Only a very small amount of such a reagent is used, since the addition of larger quantities produces entirely different effects due to the formation of oil films of appreciable thickness.

The minute amount of oil reagent, on the other hand, appears to produce some change on the surfaces of certain minerals having a metallic or semi-metallic character—zinc-blende being a typical example—which makes them less readily " wetted " by the liquor of the pulp, or, put in another way, increases the angle of contact between these surfaces and the liquid. The gangue of the ore is less affected or not at all affected by the oiling reagent, but in many cases it is necessary artificially to increase the difference between mineral and gangue by the addition of some “gangue modifying reagent” which renders the gangue more readily wetted by the aqueous liquid of the pulp. These “gangue modifiers” are as a rule alkalis or mineral acids.

The third step in the process consists in adding to the pulp some substance which causes the ready production of a stiff and lasting froth when air is introduced, either by agitation or by blowing or drawing it through the liquid in a finely divided state. Very frequently the “oiling reagent” also serves as the froth-producer. When the pulp thus prepared is treated so as to produce a froth, the oiled mineral particles adhere to the air-bubbles very firmly, the mineral-air surfaces evidently being the seat of less potential energy than the mineral-water surfaces and consequently the buoyancy of the combined bubble with its mineral burden causes it to float to the surface, where it accumulates as a very stiff mineralised froth which can be mechanically separated in various ways. A further action appears to take place, which is related to the flocculation of the mineral particles by the oil emulsion in contact with air-bubbles. This results in the attachment to each bubble of the finest mineral particles in large and heavy agglomerations, thus greatly increasing the efficiency of the whole process.

The flotation process has found its largest application in the concentration of various types of sulphide ores, and, on this ground alone, has attained very great industrial and technical importance. Its application to other minerals has, however, been actively pursued and in a great many cases with considerable success. Minerals having a more or less metallic character are particularly suited for flotation, so that native metals constitute an obviously promising application. For the treatment of finely divided gold-bearing ores the older cyaniding processes in their modern forms continue to hold their own, but a few large mines have adopted flotation. In some cases, where graphite has interfered with cyaniding, a little agitation with oil is serviceable in rendering the graphite harmless.

Application to minerals of the oxidised type is less simple, and here it seems to be necessary, in many cases, to submit the ore to a previous “activating” treatment. Considerable success in the treatment of ores of this kind has been attained by the use of sodium xanthate as a flotation reagent. Preliminary roasting in a reducing atmosphere in the hope of producing a more or less metallic surface coating upon the ore particles has been tried, while “sulphidising” by exposing the finely ground ore to the action of hydrogen, ammonium or organic sulphide has also been used with great effect in some cases. Another problem is that of “differential flotation” for the purpose of separating different metalliferous minerals in a complex ore, such as the separation of zinc-blende or sphalerite from galena. In a certain number of cases, oiling reagents have been found which act differentially upon different flotable minerals, but every particular case still requires extensive research which does not always lead to a satisfactory industrial solution.

Smelting.—Beyond its immensely important direct effects in rendering possible the economic concentration of a number of ores and in cheapening the concentration of others, the development of flotation has also profoundly affected smelting practice, since the product of flotation, being very finely divided, differs widely from the product of gravity concentration. The concomitant progress of the reverberatory furnace has been accompanied by the development of the use of powdered coal as fuel, which has attained very wide extension.

Extremely finely divided coal is blown or otherwise forced into the combustion-space of the furnace, where it burns with a flame very similar to that of a jet of gas. The obvious advantages of such a system are that the loss of heat involved in the gasification of coal in producers is saved, together with the labour and the technical difficulties involved, while most of the advantages of gas-firing can also be secured by burning powdered coal. As against this must be set the cost of grinding the coal sufficiently fine and of injecting it into the furnace, while disadvantages also attach to the fact that the ash of the coal is introduced into the furnace and thence into flues, regenerators, etc. The question of the manner in which the coal is to be powdered and conveyed into the furnace receives rather different treatment in different forms of the process, but it is coming to be recognised that extremely fine grinding is advantageous, and in one process the coal is made into an “emulsion” of coal-dust and air which is said to flow and to be capable of being pumped like a dense liquid. The coal particles appear to become coated with a closely adherent (probably “absorbed”) layer of air, and as soon as the temperature becomes high enough very rapid combustion takes place.

The use of coal-air mixtures or “emulsions,” however, implies the introduction into the furnace of a relatively large amount of cold air, and this materially affects the question of regeneration or recuperation of the heat of the waste gases of the furnace. This is also affected by the presence of the fine ash-dust which tends to clog or even to flux the tubes or chequer-work. In some furnaces, where an extremely high temperature is not required, the problem can solved by dispensing with regeneration or recuperation entirely utilising the heat of the waste gases for raising steam, etc. Anot point to be borne in mind is that a suspension of coal-dust in air r be a powerful explosive and must be treated with the care due such substances. The use of oil fuel for firing metallurgical furna has also assumed large dimensions, and rivals the extension powdered coal firing. It possesses many advantages in regard to points just discussed, so that the relative merit of the two proce becomes mainly a question of cost.

In the methods for the extraction of non-ferrous metals, d ing the period under review, there has also been an import development in an entirely different direction. This is the gr advance in hydrometallurgical processes, such as direct leach and electrolytic treatment of ores. The elimination of the G man zinc smelters during the War, so far as supplies of zinc o from the British Empire and the Allied countries were c cerned, undoubtedly supplied a stimulus to this developme which has been particularly marked in connection with extraction of zinc from its ores. The treatment of many ot ores has also come within reach of “wet way” methods, a these promise to play a large part in metallurgical extracti

III. COPPER

The effect of flotation, powdered-coal firing and the advance hydrometallurgical methods on the metallurgy of copper ha already been referred to, but mention may be made of t leaching of alkaline ores with solutions of ammonia and a monium carbonate which has been developed at the Calum and Hecla mines. Leaching methods are employed by the larg individual producer of copper—in the Belgian Congo. In rega to the metal itself, there is an increasing tendency for the exc sive employment of electrolytic copper. In part, this arises fr the increased supplies of this quality of metal, but more from t increasing demand for high purity. “Best selected” and “toug (arsenical) copper are still in demand for some purposes, pa ticularly for locomotive fireboxes and stays. The value of t arsenic has been found to lie in a certain neutralisation of t effects of oxygen; where more complete deoxidation is possi the value of arsenic is more doubtful.

With regard to finished copper, much attention has been paid certain anomalies which occur during severe cold-working, such wire-drawing, while the effect of heating the metal in a reduci atmosphere has also been further studied. A particularly interesti case of failure in copper when heated in a bath of fused sodium ch ride has been studied by the Bureau of Standards at Washingt This material became brittle and broke with a typical inter-cryst line fracture. It was shown that this arose from an electrolytic effe produced by the contact of the copper with the iron containin vessel in the presence of the fused electrolyte (Rawdon). Metal sodium is formed in contact with the copper and appears to pen trate between the crystals of the metal. A case has also been d scribed where molten solder (lead-tin) acted in a similar mann when in contact with a particular kind of brass, the so-called “ma ganese bronze” (Dickenson).

Copper Alloys.—With regard to copper alloys, some progre has been made in the difficult question of nomenclature. A co mittee appointed by the Institute of Metals has issued a n menclature report which defines the old terms “brass” a “bronze.” The former is defined as any alloy of copper wi zinc containing more than 50% of copper; if other elemen besides zinc and copper are present, they are to be named as prefix to the term “brass.” Thus an alloy containing 2% ti 28% zinc and remainder copper would be termed a “tin brass Bronze on the other hand is defined as implying an alloy of copp with tin, containing more than 50% of copper, with the sa convention in regard to additional elements. Thus an alloy co taining 10% tin, 2% zinc, and remainder copper would be call a zinc bronze. An attempt is also made to systematise nomencl ture of more complex alloys. So far as brass and bronze a concerned, these two terms are now rarely used except with the definitions named.

An immense amount of experiment and research has been devot to copper alloys. A considerable number of special alloys are n known, each possessing valuable properties. The aluminium ma ganese copper alloys have been very fully described in the nin

ort to the Alloys Research Committee of the Institution of
echanical Engineers; these include alloys capable of attaining
sile strengths as high as 52 tons per square inch. Other copper
minium alloys—known as aluminium bronzes—with or without
addition of iron, have found considerable industrial application
America, mainly as forgings, sometimes of considerable size. In
eat Britain small die-castings of such alloys are used for parts of
ctrical switch-gear. Other alloys of special strength have been
nched under various proprietary names.

For war purposes a most important part was played by the cupro-
kel alloys, containing either 15 or 20% of nickel, remainder cop-
. The production of this alloy on the very large scale required for
war revealed difficulties arising mainly from casting-defects in
slabs used for rolling. The remarkable power of this material to
lergo severe cold-working, without becoming excessively brittle,
gests that it is likely to have other useful applications beside
let envelopes, but for industrial purposes these alloys have not
n widely exploited. On the other hand, the much more expensive
nel metal has been widely pushed and has found considerable
ctical application, mainly on account of its valuable combination
great strength with great resistance to corrosion. This alloy is
nufactured "direct" by the reduction of ores from the Sudbury
rict in Canada, and special virtue is claimed on the ground that
a "natural" alloy and has not been melted together in the foun-
. It has been shown that such a claim cannot be substantiated.

orrosion.—In connection mainly with copper alloys, a large
ount of study has been devoted to corrosion, under the
pices of the Corrosion Research Committee of the Institute of
tals. The results have been embodied in a series of extensive
orts, and serve to throw new light on the corrosion, partic-
rly, of marine condenser tubes. This is ascribed, essentially,
he formation on the surfaces of the tubes of an adherent, but
no means impervious, deposit of basic salts. By restricting
circulation of water in contact with the metal under these
osits, they lead to the formation of solutions containing a fair-
high concentration of cupric chloride, and such a solution
idly attacks brass, with the resulting formation of pits and
mately of holes. It is considered that the brass as a whole is
olved under these deposits, but that in certain conditions the
per is redeposited as a spongy mass, thus leading to the
arent "dezincification" of the brass at such points. The
blem is there to prevent such adherent deposits.

he production of protective coatings on metals as a means of
venting corrosion has received much attention, the use both of
mium and of chromium plating for this purpose having been de-
ped. Cadmium plating is used chiefly for the protection of
ninium, but chromium is applicable alike to steel, copper, brass
other metals. The deposition takes place from an electrolyte of
mic acid and requires a high current density. The deposit is
ht, has a bluish white lustre and remains untarnished in the air
in many vapours. Owing to its great hardness as well as its
nical inertness, chromium plating is much superior to nickel or
r plating. The finish, however, is not yet quite as good.

he theoretical aspect of corrosion has also received much
ntion, and special research on this subject has been initiated.
ady, however, a new theory of electrochemical corrosion has
ceeded in uniting the views of those formerly advocating
rgent views (Bengough, Evans, Bancroft). The scope of the
arches undertaken by the above-mentioned committee has
n extended to include fresh-water (land) condenser plant, and
pecial sub-committee has been formed to study the whole
stion of the corrosion of aluminium alloys, while a parallel
stigation into atmospheric corrosion has been undertaken
he Non-ferrous Metals Research Association.

regard to the corrosion of aluminium alloys and its prevention,
ortant progress has been made by the development of the
odic oxidation" process. The metal is suspended as anode in an
trolyte and rapidly becomes covered with an oxide or hydroxide
ing which stops the passage of the electric current. This coating
rong and flexible and serves as an excellent protection against
osion, the protective effect being further enhanced by allowing
surface to absorb a coating of lanoline. The treated metal and
ys resist both fresh and salt water and a salt spray. The coating
be applied to alloys of aluminium so long as they do not contain
h more than 4% of copper.

IV. PLATINUM, ZINC, ALUMINIUM, ETC.

latinum.—The metallurgy of the noble metals has not under-
e any striking development during the period under review
er in regard to extraction or uses.

The cyaniding process has undergone a series of more or less minor improvements, and it was at one time thought that aluminium dust would replace zinc-dust as the precipitant for pregnant solutions. Zinc-dust, however, still predominates, and the same remark applies to the proposed method of precipitating the metal electrolytically. In regard to platinum, there has been an ever-increasing scarcity, enhanced by the complete upheaval in Russia. The Russian supply, however, is potentially the largest in the world, and production has slowly increased. Some new discoveries of platinum have been made in the Waterberg and Lydenberg districts in South Africa. Here some 60% of the metal is too fine to be caught on corduroy strakes, and some other method, such as flotation or smelting with lead, will ultimately have to be used. Another source of platinum whose importance tends to increase is the refining residue of copper and nickel.

The great rise in the price of platinum has led to the study of possible substitutes, and a number of such materials have been put forward. Thus for the "breaks" used in the magnetos of internal combustion engines, tungsten sparking points have been substituted for platinum. For chemical purposes various alloys, some containing gold and palladium, have been tried, but only with partial success, since none of them really possess the combination of properties—chemical resistance and very high melting point—which renders platinum so valuable. A number of special alloys, in which tungsten and chromium generally play an important part, also exhibit great chemical resistance, but in these cases the hardness and brittleness of the material are generally a serious difficulty. For use in chemical work on a large scale, however, a considerable number of alloys have been produced which attain a fair measure of success. Silicon itself has many advantages for some of these purposes, but in the impure form, generally met with, it is relatively weak and brittle. Platinum itself has been prepared of much higher purity than was formerly attainable, owing to contamination by calcium derived from the lime crucibles in which it was melted.

Zinc.—The metallurgy of zinc received much attention during the War. Reference has been made above to the general questions relating to zinc extraction, but mention may be made here of the growth of the enormous electrolyte plant at Risdon, near Hobart, Tasmania, where 33,000 H.P. are employed in dealing with the products of the Australian smelters, producing zinc 99·95% pure, as well as over 150 tons yearly of cadmium. There has also been great development at the United States centre at Picher, Oklahoma. Efforts are being made in Norway and Germany to obtain high recoveries of zinc from lowgrade and complex ores by electro-thermic smelting with a silicide reducing agent.

On the Allied side during the War there was at one time considerable shortage of zinc, and substitute alloys were studied for all purposes which should avoid the use of zinc. The shortage then disappeared, and at a later stage alloys consisting mainly of zinc were tried as substitutes for brass and for certain aluminium alloys. Some of these zinc alloys proved to possess remarkable properties, tensile strength exceeding 20 tons per sq. in. being obtained in cast alloys containing about 3% of copper and 7% of aluminium, remainder zinc. It was further found that these alloys could be extruded and, under certain conditions, rolled. Unfortunately, alloys of this type, when they contain both aluminium and copper, are unstable and undergo serious changes of volume, accompanied by great loss of strength, even at the ordinary temperature if kept for any considerable time.

On the German side, while there was never any shortage of zinc, this metal and its alloys were extensively employed as substitutes for other metals. Pure zinc was widely used in place of copper for electrical purposes, while zinc alloys with copper and aluminium were also largely used. Apparently, cases of failure due to the instability of these materials passed unnoticed under the stress of war; at all events, German metallurgists have described these "war bronzes" without mention of such deterioration with time, except as the result of corrosion. It may be mentioned, however, that alloys rich in zinc, which contain either copper alone or aluminium alone, do appear to be free from the trouble in question.

Aluminium.—Aluminium and its alloys have played a particularly conspicuous part and have undergone remarkable developments since 1910. Prior to the outbreak of War, aluminium itself had become relatively very cheap (below £100 per ton), and this fact stimulated interest in its use. During the War, on the other hand, while the metal itself became scarce and very dear, its applications for military purposes grew very much in importance and raised its alloys for the first time to the rank of important materials of engineering construction. Its uses arose mainly in connection with aircraft, and became increasingly important in the closing years of the War.

This rapid development of aluminium alloys under war conditions was to a considerable extent the result of progress which had been made prior to 1914. One step in this progress was marked by the section on light alloys contained in the Ninth Report to the Alloys Research Committee (Rosenhain and Lantsberry), published in 1909; but the discovery, by Wilm of Berlin, of the possibility of hardening aluminium and its alloys, when a small percentage of magnesium had been added to them, led to the next and most important forward step.

The application of this discovery to the best of the alloys, described in the above-named report, led to the production of the now widely known and used alloy " duralumin." This contains from 3 to 5 % of copper, about 1 % of manganese and about 0·5 % of magnesium. As rolled, this material has a tensile strength of about 18 tons per sq. in., but if heated to a temperature of 480° C. to 500° C. and quenched, it gradually acquires much greater strength—rising to about 26 tons per sq. in., the ductility remaining the same at about 16 to 18 % elongation on two inches.

Such a material, possessing the strength of a very mild steel combined with a density as low as 2·8, constituted a remarkable advance in wrought aluminium alloys. At quite an early stage in its history this alloy was employed for the construction of Zeppelin airships. The manufacture of the alloys was taken up in England under licence from the German patentee, and the alloy has been extensively used in the construction of British rigid airships. Its use has, however, not been free from difficulties and disadvantages, and great efforts have been made to arrive at better alloys by research in Great Britain. As a result, a series of new aluminium alloys for use in the wrought form have been developed.

The most important of these is one developed at the National Physical Laboratory and known as " Alloy Y," having the composition: copper 4 %, nickel 2 % and magnesium 1½ %. This alloy, when quenched from a temperature of 530° C. after previous cold-rolling, can be made to attain a tensile strength of 28 tons per sq. in. combined with an elongation of 20 % on two in.; its density is 2·8, and it possesses two very important further properties, viz., remarkable resistance to corrosion, and a relatively very high resistance to fatigue (repetition stresses), particularly at slightly elevated temperatures. Forgings of this alloy have been successfully used as connecting-rods in high-speed internal combustion engines, and it is finding a constantly widening range of engineering uses. More recently, a German alloy—" lautal "—in which the alloying elements are copper and silicon, has been produced industrially. It is not superior to alloy Y or duralumin.

Aluminium Alloys.—Important as are the results achieved with the wrought alloys just described, results of more immediate importance have been achieved with casting alloys of aluminium. At first these were employed mainly on more or less subsidiary castings, such as crank-cases, and for that purpose an alloy containing from 12 to 14 % of zinc and about 2½ % of copper (generally known by the number of the British Air Board Specification as " L 5 ") was very widely used. Efforts were soon made, however, to employ light-alloy castings for more important parts in aeroplane engines, viz., cylinders and pistons. Here the value of these materials lies not so much in their specific lightness as in their high thermal conductivity. In the case of the cylinder castings of air-cooled engines particularly, this is valuable in preventing distortion arising from unequal cooling of the windward and leeward sides, while in the pistons it reduces the temperature of the compression space and thus increases the density of the indrawn charge, and at the same time allows of the employment of higher compression ratios. The effect of these advantages is to increase very appreciably the power output of an engine of given size and weight, while also reducing the petrol consumption (*see* AERO ENGINES).

The alloys first and most extensively used were those of aluminium with copper, a 12 % alloy being particularly popular. Another widely used alloy contains 7 % of copper with 1 % of zinc. These alloys, although initially not as strong as some of those containing zinc, do not lose their strength so rapidly when heated, so that at the working temperature of an aluminium-alloy piston (about 250° C.) they are stronger than such an alloy as " L5." Even these alloys, however, are relatively very weak when hot—they register a tensile strength of about six to seven tons per sq. in. at 250° Centigrade. Recently, researches at the National Physical Laboratory have shown that the alloy already referred to above as "Y "—containing copper 4 %, nickel 2 %, magnesium 1½ %—is particularly strong at high temperatures, even in the cast state. It is, further, amenable to hardening by quenching and ageing even in the form of castings, and when thus treated attains a tensile strength as high as 26 tons per sq. in. at the ordinary temperature and 13 tons per sq. in. at 250° Centigrade. Many important applications are opened up as the result of the remarkable properties of this alloy.

An important development in aluminium alloys is the advent
of the " modified " alloys of aluminium with silicon, known
" alpax," " silumin," etc. It has been found that an alloy
aluminium with from 10 to 14 % of silicon solidifies with a rath
coarse, nearly eutectic, structure containing some primary cr
tals of silicon. If, however, just prior to casting, the alloy
treated either by the addition of a small amount of metal
sodium or by reaction with a flux containing sodium compoun
such as the fluoride or the hydrate, the resulting structure
profoundly altered; the eutectic structure becomes exceedin
fine and the alloy now shows primary aluminium—*i.e.*, t
eutectic concentration appears to have been altered. T
" modified " alloy shows physical properties much superior
the untreated material, particularly in regard to an exceptio
degree of ductility. The alloy yields castings having very go
clean, bright surfaces, although the avoidance of internal u
soundness is not always easy. For castings in which good appe
ance, ductility and absence of porosity is important, wh
strength is a lesser consideration, these aluminium silicon allo
offer great advantages.

Important progress has also been made in improving the soundn
of aluminium alloy castings and ingots by the recognition of the f
that gases, and particularly hydrogen, dissolved in the molten me
give rise to pin-holing and unsoundness in castings, particula
when cooled at moderate rates. It has been shown (Archbutt) th
most of the deleterious gas escapes from the metal if it is allowed
solidify very slowly, as for instance by cooling in the furnace. Su
sequent rapid remelting does not allow it to reabsorb much gas, a
castings can then be made from it of exceptional soundness. Simi
observations in regard to copper were made simultaneously
Edwards and Prytherch. A less expensive method of removi
hydrogen or other deleterious gas is that of bubbling nitrogen throu
the molten metal prior to casting (Rosenhain). This process h
proved as successful as presolidification and is coming into use.

An important process for the electrolytic refining of aluminiu
was worked out in 1925 by Edwards and his collaborators
America. Molten aluminium, to which copper has been add
to raise the density, lies at the bottom of the bath; upon it floa
the molten cryolite electrolyte, and on this again floats the pu
aluminium. The lowest layer is anode and the top layer catho
and by electrolysis the top layer of high purity metal increas
at the expense of the bottom layer. Aluminium has in this w
been obtained of more than 99·95 % purity, and the propert
of this high purity metal are distinctly different from those
the purest commercial metal previously obtainable (99·7 %).
Magnesium.—During the latter part of the period unc
review, this metal began to acquire technical importance. Hi
price and great corrodibility had formerly prevented its use, b
the price has been much reduced and, if the demand increas
sufficiently, this may become lower than that of aluminium,
satisfactory raw materials are plentiful and the reduction proc
could be rendered equally economical. As regards corrosion, t
production of metal of higher purity, and especially free fr
chlorides derived from the electrolyte, shows much better resi
ance to atmospheric corrosion than the older material.

The mechanical strength of magnesium and its alloys never a
proaches that of the better aluminium alloys, but their greater lig
ness offers some advantages. Magnesium and some of its allo
have been successfully used, particularly in France, for pistons
internal combustion engines and for other special purposes. T
thermal conductivity of these materials, however, is decide
inferior to that of aluminium alloys, and this is likely to lessen t
advantages to be gained from extreme lightness. As further impro
ments are made, however, magnesium alloys are likely to prove
increasing technical importance.

Berylium or glucinum metal has been produced in reasona
quantities, although still at a very high laboratory cost. T
combination of great lightness, considerable resistance to c
rosion, high strength and high melting point found in t
metal may render it technically interesting provided that t
cost can be made reasonable and that it can be produced in
malleable form. The latter has not, so far, been done.
Nickel.—This has received a wide range of new applicatio
partly as the result of the need of the nickel industry to fi
new uses when the principal older use—for armament purposes
came practically to an end after the Washington Conference.

Among the more important developments are the alloys for use at ry high temperatures. Alloys of nickel and chromium containing rious amounts of iron and manganese have been known for a con- lerable time as " Nichrome," and proved valuable for such uses as ctric resistance heaters for temperatures not much above 1,000° entigrade. More recently these have been improved upon by a gh-purity alloy consisting solely of nickel and chromium (80 % Ni., % Cr.), and this alloy also exhibits remarkable strength at high mperatures (up to 800° Centigrade). In this respect, however, it is t appreciably superior to the best of the special " steels " which ve been developed for use at very high temperatures. These ually contain large amounts of both nickel and chromium, to which ngsten is sometimes added, the proportion of iron in some cases ling as low as 54 %. The increasing use of very high temperatures engineering practice lends special importance to these materials.

Other Metals.—Developments in the remaining metals are mostly a minor nature. Progress has been made in connection with *cobalt.* s use in steel and in certain special alloys has already been men- ned, but it has also been shown to give a more adherent and more rable electro-plate coating than nickel, and it is important to note at its resemblance to nickel is not nearly so close as was previously pposed. In regard to *lead* and its alloys, a remarkable develop- ent has been that of alloys with the rare-earth metals, particularly cium and barium. These confer a remarkable degree of hardness lead, and a special alloy of this kind is finding application as a aring metal.

V. PHYSICAL METALLURGY

Side by side with, and to a great extent furnishing the basis for, e development in the treatment and use of metals and their oys, there has been a very great development of metallurgical ence in the direction of " Physical Metallurgy."

Alloy Systems.—A very large amount of work has been de- ted to the further and more detailed study of the constitution alloy systems. A number of the somewhat rough preliminary terminations of the equilibrium diagrams of most binary alloy stems previously made, have been revised and rendered more curate. In ferrous alloys, the iron-carbon system has received ich further study, particularly in regard to the critical points iron itself. Important work at the Bureau of Standards, U.S.A. urgess and Crowe), has firmly established the three well- own critical points, A_1, A_2 and A_3, and has shown that pre- ous attempts on the one hand to discredit the very existence A_2 (Carpenter), and on the other to show that it was a double int (Arnold) were based on experimental error. On the other nd, German investigators (Ruer, Hanemann) have estab- ied the existence of a higher critical point, which in pure iron curs at a temperature very close to 1,400° Centigrade.

In connection with the critical points, considerable attention has en devoted to the whole question of allotropy. A Dutch school of restigators (Cohen) have sought to show the existence of numerous otropic transformations in many metals, but their conclusions are sed on extremely slight evidence derived from determinations of nute irregularities in density changes. On the other hand, the panese school (Hondo) seek to show that the A_2 transformation in n is not allotropic in character, and this view is confirmed, to a tain extent, by strong evidence that the passage through this nt does not involve any change of crystallisation—evidence which s recently been confirmed by X-ray methods. The matter, how- er, turns upon the definition of allotropy.

In addition to the iron-carbon system, the iron-nickel, iron- romium, the manganese-carbon and nickel-carbon systems have en carefully investigated. The systematic study of the alloys of n, in the first place free from carbon, has been begun at the tional Physical Laboratory under the auspices of a special com- ttee. The production of iron, chromium, manganese and silicon a very high state of purity and a study of the iron-oxygen system some of the results already obtained. In non-ferrous alloys, nsiderable attention has been given to the alloys of zinc, a portion the ternary system copper-aluminium-zinc (alloys rich in zinc) ving been very fully worked out (Haughton, Bingham).

The allotropy of zinc itself has also been very thoroughly studied enedicks, Bingham) and the reality of the transformations estab- ned. Great advances have been made in the knowledge of the uilibria of several of the important alloy systems in which alu- nium is the predominant metal. The ternary systems aluminium- c-copper, aluminium-iron-silicon and aluminium-magnesium- con (Hanson, Gayler) have been fully worked out so far as the oys rich in aluminium are concerned. For the representation of the ults of such investigations a new type of model has been devised osenhain) in which the various equilibrium surfaces are repre- ted by systems of wires coloured to indicate the phases concerned each transformation.

The Aluminium-magnesium-silicon System.—The study of the aluminium-magnesium-silicon system has proved particularly important, throwing light on the age-hardening properties which are found in many aluminium alloys containing magnesium. The magnesium in these alloys is present as a compound Mg_2Si, which is more soluble in solid aluminium at high temperatures than at the ordinary temperature. Quenching such an alloy from a temperature just below its solidus retains the compound in solid solution and in this state the alloy is soft. Gradually, however, at the ordinary temperature and more rapidly at slightly higher temperatures, this super-saturated solid solution deposits the excess of dissolved compound in an extremely finely divided condition, accompanied by a gradual hardening of the alloy.

This process is strictly analogous to that which can be brought about in certain alloy steels which can be rendered (or kept) completely " austenitic " (homogeneous solid solution) by quenching; they are then soft and ductile, and do not undergo hardening while at rest at the ordinary temperature. If the temperature is raised so as to bring about " tempering " the solid solution breaks down in precisely the same way as indicated above and the steel becomes hard (and also magnetic). It would thus seem that hardening as the result—direct or indirect —of quenching is due to the separation from solid solution, in a state of extremely fine division, of a phase the formation of which had been suppressed by quenching.

According to the theory of amorphous metal (*see* below) each of the minute crystallites of the phase thus separated will be surrounded by a zone of amorphous metal, which is itself very hard. If the minute crystals thus separated are sufficiently small and numerous, the result will be that a considerable proportion of the whole alloy will be thrown into the amorphous state, extreme hardness resulting. On this view, the martensite of hardened steel should consist mainly of minute crystallites of alpha-iron embedded in an amorphous matrix consisting of iron and carbon (or carbide) in solution in it. This suggested constitution of martensite readily accounts for its hardness and for the fact that it is magnetic, and—in view of the intimate manner in which the minute crystallites of alpha-iron are embedded in unyielding and un-magnetisable amorphous metal—accounts also for the magnetic hardness of the martensitic steel. This view is further confirmed by the observation that the chemical behaviour of quench-hardened steel is in certain respects closely similar to that of the same steel hardened by cold work and thus rendered partially amorphous (Whiteley). Finally, it has recently been shown by X-ray methods that the space lattice typical of alpha-iron is present in martensitic steel (Westgren).

Theory of Amorphous Metal.—The theory of amorphous metal just mentioned has played an important part in scientific metallurgical thought during the period under review.

The conception that metal could be rendered amorphous by mechanical disturbance of its crystalline structure was originated by Beilby, in the first instance, to account for the phenomena observed by him and others in connection with the polishing of metals and other substances. Beilby further applied the conception to explain the hardening which metals undergo as the result of plastic deformation (cold work) by suggesting that layers of amorphous metal are formed on the surfaces on which internal slip occurs during plastic straining. Both these theories are widely but not universally accepted in England and America, but find opposition on the Continent. More recently Rosenhain has brought forward a conception which has already been present in the minds of many other investigators (notably Osmond) in a less definite form, that a film or thin layer of amorphous metal exists in the inter-crystalline boundaries of all metals, quite apart from any effects of strain. This view has been vigorously contested, but experimental evidence in its confirmation has been steadily accumulated.

The most striking series of facts supporting the " amorphous cement " theory is connected with the behaviour of the inter-crystalline boundaries under stress. In normal circumstances these boundaries are stronger than the crystals themselves, so that fractures of metals generally occur by breaking through the crystals and not by pulling them apart. It has, however, been shown that at a high temperature near to, but definitely below, the melting point, pure metals can be easily caused to break with a perfectly inter-crystalline fracture (Rosenhain and Ewen). This is ascribed to the greatly decreased viscosity at such temperatures of the inter-crystalline amorphous metal, which is regarded as possessing the properties of a viscous under-cooled liquid. The actual viscosity, however, depends very much upon the nature of the metal and upon the temperature—the farther a metal is below its normal melting-point the higher the viscosity of the amorphous phase.

Accordingly, in some of the softer metals and alloys the amorphous material is sufficiently mobile to allow of sensible movement in relatively short times. Thus, an alloy of zinc with copper and aluminium has been discovered which, in the cold-worked state when it is partially amorphous, behaves very much like pitch; it will bend to any desired extent if allowed to do so gradually, but breaks short if rapid bending is attempted. Similarly, the inter-crystalline cement in certain metals and alloys, although it proves stronger than the crystals when the metal is loaded at any normal rate, appears to be capable of giving way by some form of viscous or visco-elastic movement under very prolonged loading such as that due to internal stresses.

Season Cracking.—Much attention has been devoted to the study of fractures occurring in various metals as the result of the application of internal or other prolonged stresses. In brass these phenomena have become known by the misleading term "season cracking," but strikingly similar phenomena have been found in a number of other metals, including certain alloys of aluminium, platinum and steel (Rosenhain and Archbutt). In the case of brass, steel and aluminium alloys, certain types of chemical reagents which act preferentially upon the material in the crystal boundaries contribute to the occurrence of such fractures, which are typically inter-crystalline (Moore and Beckinsale). At the same time in the case of the aluminium alloys at all events such chemical action serves to accelerate the fractures, but is not essential to it since it occurs, although more slowly, in high vacuum or in an atmosphere of pure dry hydrogen (Rosenhain and Archbutt). In the case of brass it seems probable that "season cracking" can occur without the intervention of any chemical action.

Similar types of cracking which have been discovered in mild steel, however, appear to be very closely associated with the effects of certain chemicals, such as concentrated solutions of alkalis, fused ammonium nitrate, etc. While there are still some metallurgists who refuse to think in terms of an amorphous inter-crystalline cement (Hatfield, Tammann), the great majority of investigators are agreed that, directly or indirectly, this conception serves to explain the occurrence not only of inter-crystalline fractures under prolonged loading but also a number of other phenomena associated with the crystal boundaries.

Intimately connected, also, with the nature of inter-crystalline boundaries are the important phenomena of recrystallisation and crystal growth, which are of fundamental importance with all annealing and heat-treatment operations, and have been studied in great detail. One of the most striking features is the relatively rapid formation of large crystals in certain conditions. Thus in an oblong piece of metal which has been severely strained, and is then heated in such a way as to be well above the usual temperature of recrystallisation at one end and well below it at the other, a zone is found in which very large crystals are formed; this may occur either as the result of a temperature-gradient being applied to a uniformly strained piece of metal or of the application of a suitable uniform temperature to a piece of metal in which there is a strain-gradient.

The explanation appears to be that for a given degree of previous plastic strain there is a temperature most favourable to rapid crystal growth (Jeffries). An interesting practical application of the ideas derived from the study of these phenomena is the production of wires of certain metals, notably tungsten, which have been so treated as to consist, for considerable lengths, of single long crystals. This result is achieved by drawing the cold-worked wire into an annealing furnace at a suitable temperature, at precisely the right rate. The tungsten wire thus produced is particularly valuable for the manufacture of electric lamp filaments (*see* ELECTRIC LIGHTING), and it has also been shown to possess interesting elastic properties (Wartenberg) which are readily accounted for by the absence in such material of any amorphous inter-crystalline material the viscous or visco-elastic properties of which affect the behaviour of the wire.

Much study has also been devoted particularly to the recrystallisation of aluminium after cold-working, and as a result very large single crystals of aluminium have been produced (C penter and Elam). This has opened the way for the study single crystals under strain (Taylor and Elam) and unc fatigue (Gough and Hanson), (*see* FATIGUE OF METALS). It also given the impulse for the production and study of sin crystals in other metals (Davey, Bridgeman, Czochralski). T general result emerges that in most respects single cryst behave very much like aggregates, but possess greater du tility and, in the case of copper, have an appreciably high conductivity. Their mode of deformation under strain and tigue is found to confirm the original theory of deformation slip on crystallographic planes (Ewing and Rosenhain), extensive research on fatigue phenomena both in single cryst and crystal aggregates (Moore, Jasper, McAdam, Gough, Je kin) has as yet failed to produce a satisfactory explanation fatigue failure. The fatigue range, however, has been dissociat from the "elastic limit" and found to be related rather to ultimate strength.

The application of X-ray methods of crystal analysis to t study of the atomic structure of metals has received mu attention. The normal crystal lattices of almost all the kno metals have been worked out, as well as those of a number alloys (W. H. and W. L. Bragg, Hull, Bain, Wyckof, Westgre Debye, Scherrer, Wever, Owen and Preston and many other (*See* CRYSTALLOGRAPHY; X-RAY.) The majority of metals ha either a face-centred or body-centred cubic lattice; a few (zi cadmium, etc.) have a close-packed hexagonal structure, wh the more brittle metals show structures of lower symmetry. T lattice structures of solid solution alloys are found to be those the parent or solvent metals often either expanded or contract by the addition of the dissolved metal. On the basis of th structure a general theory of the properties and behaviour solid solutions has been worked out (Rosenhain) which affor satisfactory explanations of their behaviour on melting a freezing, their hardness and electrical conductivities and t power of different metals to form solid solutions.

X-ray methods have also been used, as already mentioned, very important work on the behaviour of metal under strain a fatigue. The effect of cold working on the atomic structure h been particularly fully investigated, and it has been show (Polanyi, Mark, Körber, Sachs) that cold working, such as co rolling, not only elongates the crystals of a metal and sets disturbances of the lattice structure, but sets the crystals in orientation which tends to place one of their axes in the directi of rolling. Annealing, although it rapidly brings about recrysta lisation into equi-axed crystals, does not necessarily abolish th oriented structure, probably because the newly formed crysta tend to assume the orientation of their predecessors. Th directional structure—called by German workers the "fibre structure of cold worked metal—is completely removed only b annealing at very high temperatures.

VI. ORGANISATION OF THE INDUSTRY

Certain institutions and organisations have attained impo tance as factors in metallurgical progress. The Imperial Mi eral Resources Bureau, merged in the Imperial Institute, ha published a large amount of information, mainly in regard to th mineral resources of the British Empire. The continued progre and growth of the Institute of Metals has been a marked featu of metallurgical activity; this body has now attained a membe ship of over 1,700. In America an Institute of Metals has bee formed on different lines, as part of the Institute of Mining an Metallurgical Engineers.

The British Engineering Standards Association, formerly th Engineering Standards Committee, exerts a powerful influen on the metallurgy of those metals which form the materials engineering. The issue of standard specifications for a lar number of non-ferrous metals has been undertaken. In conne tion with the British Government Department of Scientific an Industrial Research, a Non-Ferrous Metals Research Associa tion has been formed and has carried out important research particularly in connection with copper, brass, aluminium, th ointing of metals, die-casting, etc. The British Cast Iron esearch Association has been mentioned.

This brief summary of the developments of metallurgical ience deals only with a few points of outstanding interest.

BIBLIOGRAPHY.—For iron and steel metallurgy, industrial as well scientific, the *Journal of the Iron and Steel Institute*, London, ould be consulted for original publications and abstracts which ver the literature of the whole world on this subject. In addition, cellent abstracts will also be found in the metallurgical section of e journal of the *Society of Chemical Industry*, and in such journals *Stahl und Eisen*, the *Revue de Métallurgie* and *The Metallurgist* upplement to *The Engineer*). In addition *The Iron Age, the Iron d Coal Trade Review* and similar journals may be mentioned. For neral metallurgy, see the annual volumes of *Mineral Industry* and *he Journal of the Institution of Mining and Metallurgy*. For the on-ferrous metals, see *The Journal of the Institute of Metals* (ab- racts as well as original papers), *Revue de Métallurgie* and several erman journals, *Zeitschrift für Metallkunde, Metall und Erz, Zeit- hrift für Anorganische Chemie*, and the appropriate section of the *nerican Institute of Mining and Metallurgical Engineers* (Ameri- n Institute of Metals). The publications of the U.S. Bureau of andards (Washington) and of the National Physical Laboratory eddington, England) are important. The Faraday Society (Lon- n) has published in its *Transactions* several "general discussions," cluding particularly one on *The Failure of Metals under Internal d Prolonged Stress*, another relating to metallurgical microscopy, e on the application of X-rays and one on *The Physical Chemistry Steel Making*. (W. RN.)

METCALF, WILLARD LEROY (1858–1925), American artist *e* 18.257), died in New York City March 9 1925.

METEOROLOGY (*see* 18.264).—Since 1910 considerable ad- nces in meteorological knowledge have been made both on e observational and the theoretical sides.

The Upper Atmosphere.—During the years before the War servations on the temperature and humidity of the air strata re rapidly accumulating, more particularly from a network of tions spread over Europe, and since the W. and N. of Europe subject during the winter to the passage of many deep cy- nic depressions, the conditions of temperature in cyclones d anticyclones up to a height of some 20 km. (12½ m.) had come known. The brief tables which were all that were ilable to Cleveland Abbe in 1909 had been supplemented by ch information, drawn up and arranged for the European ults by Lt.-Col. E. Gold (M.O.No. 210e, *Geophysical Memoirs*, . 5), by Dr. Wegener for the Continent (*Die Temperatur- hältnisse in der freien Atmosphäre*, III. Band, Heft 2/3, Leipzig, 9) and for Russia by Dr. Rykatchew (*Meteorologische Zeit- rift*, Jan. 1911). In 1916 a summary of the information ilable about the upper air was drawn up for the Meteoro- ical Office but not published. It quoted freely from Gold's er but included the results of observations up to 1916. This nmary together with certain theoretical matter was published 1919 under the title "Characteristics of the Free Atmos- ere" (M.O. 220c, *Geophysical Memoirs*, No. 13), and from it following abstract summarising our present knowledge of strata from 0 to 20 km. is mostly taken.

emperature.—As the surface of the earth is left the temperature of air decreases with increasing height, and when the great varia- ns of climate and of the conditions prevalent in different parts of earth are considered it is remarkable how uniform is the fall of perature, now commonly called the lapse rate. The height to ich it extends is variable, but in all places in which observations e been made, the lapse rate up to 8 km. has been found close to C. per kilometre. This holds between 2 and 7 km. not indeed ctly but approximately, for summer and winter and for places as apart as the equator and the Antarctic in lat. 78° S. Thus in avia the lapse rate up to 8 km. is 6·1° per km.; at Petrograd it ·8°. In England in the winter it is 5·8°, in the summer it is 6·0°. ese are means, but the rule holds quite well even for the individ- case, for if in one part of the 8 km. the lapse rate is small this is ally compensated for by its being large in the other part. The y important exception that has been found so far is in regions and times where the temperature is extremely low, as in Siberia or ada or the Antarctic in the winter. In such instances the bot- layer is unduly cold and the lapse rate is negative over the first m., so that the rule would make the upper air temperature too low. it must be remembered that the daily variation of temperature s not extend upward more than one or two km., so that the mean for the day rather than the precise temperature at the moment should represent the surface temperature. This layer, in which temperature falls with increasing height, is called the *troposphere*.

At a certain height, which varies with the latitude, with the barometric conditions, and with the season, the fall of temperature ceases, and the air up to the greatest heights that have been explored remains at a nearly uniform temperature in the vertical direction. This upper part in which there is no lapse rate is called the *stratosphere*. The boundary between the two parts is found at about 16 km. near the equator and at 10 km. in northern Europe. Over England its mean height is 10·5 km., falling to rather below 10 km. in the winter, and rising to over 11 km. in the summer. In the centre of a deep cyclone the value may easily fall to 8 km.; in an anticyclone it may exceed 12 km.

The temperature of the stratosphere is below 200° A. over the equator and in tropical regions; it is above 220° A. in northern Europe. In Canada it seems to be lower in the summer than in the winter. These anomalies are roughly expressed by the rule that the mean temperature of the air column taken with regard to height from 0 up to 19 km. is approximately the same in all parts of the earth. There is probably a physical reason for this, and it explains the unexpectedly low temperature above 14 km. over the equator and the curious reversion of temperature between summer and winter over Canada (Toronto) where the seasonal range is very large.

The annual range of temperature in the troposphere does not differ very greatly from the range at the surface; in island and coastal climates like England it is rather greater in the upper parts than at the surface; in continental climates the surface has the greatest range. In the stratosphere the range is much reduced and, as already stated, appears in Canada to be reversed although enough observations are not yet available to make this absolutely certain.

Whether or not there is any regular diurnal change of temperature above 2 km. height is uncertain; all that can be said is that if there be any its amplitude is certainly less than 1° Centigrade.

The mean annual temperatures are given in the accompanying Table I. In Europe the probable error of any value is about 1° C.; for Canada and the equator owing to paucity of observations it is greater, especially above 15 km., where it may reach perhaps 3° Centigrade. Over Europe the mean temperature does not change from 14 to 20 km. and does not change much over Toronto. Over the equator the lowest temperature, which is about 193° A., is not reached under 16 or 17 kilometres.

TABLE I. *Mean Atmospheric Temperature*

The values are in the Absolute scale with the first "2" omitted. 273·0° = 0° C. = 32° F.

Height km.	Petrograd	Scotland	Manchester	Berlin	England, S.E.	Paris	Strasbourg	Vienna	Pavia	Mean for Europe	Toronto	Equator
14	23·5	22·0	20·5	18·7	18·9	19·1	17·9	19·6	17·7	19·1	12·5	3·0

Pressure and Density.—The temperature of the air having been found by observation, the pressure and the density are easily found up to the height to which the observations extend. In the same way the mean pressures and mean densities can be determined from the mean temperatures without appreciable error provided the mean pressure at the surface is known.

In the lower strata the pressure at any particular height is naturally most dependent upon the surface pressure, but since the air is lighter, bulk for bulk, when it is warm the pressure decreases less rapidly than usual in a warm area, and the pressure at any given height depends more and more upon the temperature of the underlying air as that height increases. Thus it comes to pass that in the hot regions of the earth, say in the belt included between the two tropics, the pressure at the height of 9 km. is very much greater than it is at the same height over temperate latitudes, and the pressure gradient which causes the prevailing westerly winds of the cirrus level is thus produced. At a height of 20 km. the surface pressure has ceased to have much effect, and it requires a rise of nearly 20 mb.[1]

---

[1] The average pressure of the atmosphere at sea-level being reckoned as 1 bar = 1000 millibars (mb.). 1 mb. = 0·0295306 in. mercury at 32° F. in lat. 45°.

in the surface pressure to produce a rise of 1 mb. at 20 km., whereas a change of 1·5° C. in the temperature of the air column will produce that effect. It has been stated that the mean temperature of the air column up to 19 km. is much the same in all parts of the world, and it follows that the same level is one of nearly uniform pressure.

The pressures are given in Table II. at various stations for heights up to 20 kilometres. The values for Canada and the equator at heights above 15 km. are not very reliable owing to paucity of data.

The densities are given in Table III. The variations in the density became of great consequence during the War on account of their influence on the range of projectiles; they depend on the connection which has been found to exist between temperature and pressure.

Statistical Methods.—Statistical methods have been much in vogue of late years, and it is necessary to indicate how the method of correlation has been used for forecasting and for elucidating meteorological problems. A large number of correlation coefficients have been determined between various meteorological events, and the values of many of them are given in the *Computer's Handbook*, M.O. 223, Section V.—Tables, published by the Meteorological Office.

The advantage of a correlation coefficient in estimating the connection if any between two events, is that it expresses the connection as a decimal, which must lie between 1 and −1, and thus renders the connections between different pairs of events comparable with each other. The velocity of the wind and the steepness of the barometric gradient may be taken as an example. The actual connection is obvious from the daily weather charts; on some it is well marked, on others badly, but the fact that there is a connection is quite apparent from even two or three charts. The correlation coefficient is about 0·70.

The application of the method of correlation to forecasting ca hardly be looked upon as very successful. Two highly correlate events are required happening with a definite time interval betwee them. A correlation coefficient may be high accidentally if it b founded on too small a number of instances, but genuinely hig coefficients between meteorological events occurring with more tha a few days' interval between them are hard to find. The most successful instance is perhaps the forecast of the monsoon rain c India by Sir G. T. Walker from the correlation between it and sundr other events occurring in the spring of the same year or earlier. I this case the correlation coefficients on which the forecast is base have values of about ·50; if values of ·80 or ·90 could be obtaine very much greater success would be secured. There are a fe coefficients of from ·70 to ·80 between the rainfall at various perioc and the subsequent yield of sundry crops. Thus in the easter counties of England if April and May be wet it is a practical ce tainty that there will be a large hay crop, and if the autumn be dr there will almost certainly be a large crop of wheat the next yea Mr. R. H. Hooker has calculated a most interesting set of figure relating to the correlation between the weather and the crops, an the problem has been re-analysed by R. A. Fisher and W. A. Mackenzie, *Quart. Jour. R. Meteor. Soc.*, July 1922. Similar work ha been done for the potato crop in America by J. Warren Smith, an many correlation coefficients relating to agricultural matters ar available from Sweden and elsewhere.

The case is different where correlation is resorted to for the pu pose of elucidating some physical process in the atmosphere; here small coefficient is just as likely to give information as a large on But the interpretation of the meaning of the coefficient is ofte difficult, and in many cases the value obtained is quite different fro that which most meteorologists would have expected.

Sir G. T. Walker in addition to his statistical work on the mo soon rain has published several sets of correlation coefficients, ar amongst them a set of 100 showing the correlation between tl sunspot number and the temperature at 100 stations well distribute over the earth's surface. The correlation is negative and sma but it is large enough to be significant and to prove that during tl 40 or so odd years considered the temperature of the earth as whole was lower at the time of the sunspot maxima than at the tin of the minima. It is commonly supposed that the sun is giving o most energy when its surface is most disturbed, and this idea h been confirmed by direct observation of the radiant heat. A pe fectly satisfactory explanation is at present wanting. Walker al correlated between sunspots and rainfall, and found the coefficie too small to be significant. However, in none of these cases has tl work been wasted, since important conclusions have been establishe

For high correlation coefficients one must take data relating to tl upper air. The relation between pressure and temperature is remarkable and has such a close relationship to the theory of cyclor and anticyclones that it will be treated separately. The correlati coefficients between the thickness of the troposphere, a height co monly denoted by H_0, the surface pressure, the temperature of t stratosphere and other variables often exceed 0·70, and the ge erally high values show quite plainly that there is an ordered s quence in the processes going on above, which is strikingly abse from the surface phenomena.

Cyclones and Anticyclones.—In a cyclone the troposphere is co and the stratosphere warm, in an anticyclone the reverse is t case; in a cyclone the tropopause is low, in an anticyclone hi Thus as an area of low pressure passes across the map the followi changes occur in the various air strata above. The deficiency pressure is about the same from the surface up to some 10 kn

bove which it falls off rapidly until the normal value for the height
s reached at about 18–20 kilometres. The temperature from about
to 8 or 9 km. falls, and from 10 to 20 km. it rises. The height at
hich the lapse rate ceases, the limit of the troposphere falls. These
tatements are based on the very high correlation coefficients that
re found to exist between pressure and temperature. It will be
een from the accompanying Table IV. (which gives the correlation
efficients) that close to the surface the correlation is low, but it is
ery high from 4 km. to 8 kilometres. There are probably two rea-
ons for this. The surface temperature is governed by many consid-
rations—the time of day, the state of the sky, the strength and direc-
on of the wind; higher up these disturbances do not apply, for, as
as been already stated, the diurnal variation is very shallow and
e correlation between the components of the wind and the tempera-
re is surprisingly small above a few km. height. Secondly, it may
ell be that the chief item in determining the temperature is the re-
nt vertical motion of the air, and a systematic vertical flow of air
ther up or down is plainly impossible quite close to the surface. The
e and fall of the tropopause (H_c) and the regularity with which it
curs is shown by the high correlation, ·84, between it and the pres-
re at 9 km. height. There is hardly a single instance of observa-
ns made in Europe at a time of really low barometer in which H_c
s not been found well below its average value. The dependence
the temperature of the stratosphere on the barometric conditions
not so close, the correlation being only ·50; but based on some
ndreds of observations as these correlation coefficients are, ·50
amply significant. Still the importance of a correlation in general
pends upon its square rather than upon itself, and the significance
·50 is very different from that of ·90 or ·85.

TABLE IV. *Correlation Between Pressure and Temperature*

Height, km.	0	1	2	3	4	5	6	7	8	9	10	11	12	13
Jan.–March	−·02	·54	·82	·79	·86	·85	·84	·87	·91	·81	·35	−·32	−·38	−·37
April–June	·14	·28	·49	·79	·89	·89	·92	·87	·81	·45	·20	−·12	−·24	−·01
July–Sept.	−·02	·31	·56	·72	·75	·81	·83	·87	·87	·88	·43	−·08	−·41	−·19
Oct.-Dec.	·33	·56	·76	·77	·83	·87	·85	·85	·86	·78	·29	−·24	−·34	−·50
Means	·11	·42	·66	·77	·4	·85	·86	·86	·86	·72	·32	−·19	−·36	−·28

One noticeable result of this high correlation between pressure and
nperature is that the density is not subject to much variation
'e close to the surface, for a high pressure and a high temperature
upon the density in opposite ways, and since they occur together
density remains comparatively unchanged. (*See* also below, *The*
cting of Air Masses from Different Climates.)

Stability for Vertical Displacements; Available Energy.—The
e of decrease of temperature with height is normally less
n the 10°, C. per km. by which clear ascending air is cooled by
iabatic expansion. Consequently a small portion of air, if
cibly raised or depressed, usually tends to return to its original
el. The periodic time T of its vertical oscillation, if undamped,
been calculated by Väisälä (*Soc. Scient. Fennica, Comm.*
ys. Math, II., vol. 19, p. 38) to be

$$T=2\pi\sqrt{\frac{\theta_0}{g(\gamma_0-\gamma)}}$$

ere θ_0 is the absolute temperature of the air in the equilibrium
el, g is the acceleration of gravity, γ is the actual decrease of
perature per unit increase of height, γ_0 the adiabatic value of
Thus at a height of three km. T is normally about ten min-
s, while in the stratosphere T is about five minutes.

ny energy that there may occasionally be in a vertical col-
n available for producing thunderstorms or other local dis-
bances has been made conspicuous by Sir Napier Shaw, who
plotted upon a special chart observations of temperature
inst those of pressure at the same height, so as to produce,
hout calculation, the entropy-temperature-diagram familiar
ngineers. Fig. 1 is a simplified sketch of it showing the ob-
ation for Benson, Oxfordshire, on July 5 1923, 7 P.M. He
rds the dry air as the working substance and calls its en-
y the "realised entropy," while the moisture he regards as
ely a reservoir of latent energy.

et A and B be two points where the curve representing the
ervations cuts the same adiabatic for cloud. If a sphere of
mass of cloud at A is pushed up it will follow this adiabatic.
e may assume that the surrounding air, in descending to
the place of that which has risen, does so by a very small
lacement spread over a large horizontal area, and in such a
that unit mass descends across each level surface, then
t has occurred will apparently be indistinguishable, as far
nergy changes are concerned, from the passage of a unit mass
round the thermodynamic cycle from A *via* the adiabatic to B and back by the observed curve. Then, from the known properties of the entropy-temperature-diagram, the mechanical energy will be proportional to the area enclosed between the curves, and will be consumed or given out according as the observed curve lies below or above the adiabatic.

Actually two diagrams are employed, in order to represent humidity as well as temperature and pressure.[1]

Radiation in the Form of Electromagnetic Waves.—Just as a point has no parts and no magnitude, so a single direction contains no radiant energy. To mark off a definite flux of energy we must have two areas not in the same plane. For simplicity let us think of two square centimetres placed one metre apart and both normal to the line P Q joining their centres P and Q. We are now able to define the "intensity of radiation" in the direction P to Q as being 10^4 times the amount of energy that goes through both square centimetres in the order P to Q in one second.

The intensity of radiation $K_\nu d\nu$ in the range of frequencies of vibration between ν and $\nu+d\nu$ has been shown to have the following value inside a black enclosure at a uniform temperature θ absolute centigrade,

$$K_\nu d\nu=\frac{2h\nu^3}{c^2}\left(e^{\frac{h\nu}{k\theta}}-1\right)^{-1}d\nu$$

where c is the speed of light, $h=6\cdot55\times10^{-27}$ erg sec, $k=1\cdot34\times10^{-16}$ erg degree^{-1}. (Planck, *Vorlesungen über die Theorie der Wärmestrahlung*, Barth, Leipzig.) This is known as the "full" radiation. Further it was proved by Kirchhoff that if a portion of air absorbs a fraction α of the energy in a ray of frequency ν then that portion emits in the direction of that ray the same fraction α of the full radiation, $K_\nu d\nu$, corresponding to its temperature θ.

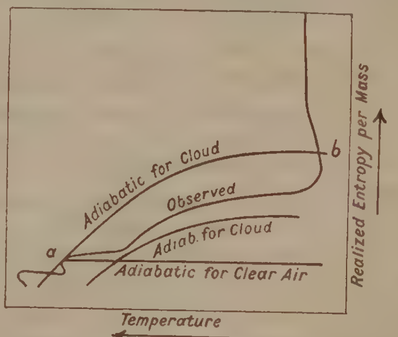

FIG. 1.—Diagram of "air" entropy.

Through any sphere of one centimeter diameter in the atmosphere radiations of various frequencies are passing simultaneously in all directions without blocking each other's paths. A division at a wave-length of three microns has nearly all the energy of solar origin on the short side of it and nearly all the energy of terrestrial origin on the long side.

When a ray passes through a centimetre length of atmosphere its energy is in general divided into three parts. One part, almost unchanged in wave-length, is turned aside and scattered in most directions. Another part is absorbed, that is to say—changed into heat-energy of the air. Whatever is left goes straight on unchanged in wave-length. The fraction that is scattered in unit length of path depends on the wave-length and the presence of dust and cloud particles. Even air molecules scatter, and more so in the shorter wave-lengths. Hence we see a yellowish sun in a blue sky (Rayleigh). The fraction that is absorbed in unit length of path depends on the wave-lengths and the various gases present; N_2, O_2, O_3, CO_2, H_2O, each absorbing strongly characteristic wave-lengths. At the same time each small sphere of atmosphere is sending out, at the expense of its heat energy, long-wave radiations equally in all directions.

---

[1] See the report of the meeting of the International Commission for the Investigation of the Upper Air, held in London 1925 (M.O. 281 published by H.M. Stationery Office, London).

With such an abundance of processes going on simultaneously the difficulty of the observer has been to separate that one which he wished to observe; and the difficulty of the theorist has been to include them all without making his theory too cumbrous.

"Long Wave" Radiation.—W. H. Dines (*Geophysical Memoirs of the Meteorological Office*, No. 18) has measured the radiation which will not go through a glass plate and which reaches the earth from different zones of the sky. He finds that the intensity of radiation from a thick fog is within a few per cent. of that from a "full" radiator at the same temperature; whereas the intensity of radiation from a clear zenith sky at sunset ranges from about 0·65 of that from a grass meadow in December to 0·74 of it in September. The meadow was practically a full radiator. From the way in which the intensity increases as the zenith distance increases, W. H. Dines concludes that there must be at least two groups of radiation differently absorbed; one group comprising two-thirds of the energy is half absorbed in passing normally through a horizontal layer of clear air 100 millibars thick, the other group, comprising one-third of the energy, is only $1/20$ absorbed in this way; whereas 100 millibars of thick fog absorb eight-tenths or nine-tenths of all the incident energy. The sum of the radiations received by a horizontal square centimetre from all parts of the sky amounts to 500 gr.-cal. per day on the average for clear skies, or 700 for fully clouded skies, while at 10° C. a full radiator gives out 711 of these units.

A similar but not identical account is given by A. Angström (*Quar. Jour. Roy. Meteor. Soc.*, April 1924). He divides the energy sent out by a full radiator into three groups of wave-lengths comprising one-fourth, one-half, one-fourth of the whole energy. For the first group a clear moist atmosphere is almost perfectly transparent. The second group is almost totally absorbed in the first 30 metres above ground when the vapour pressure is 10 mm. of mercury. The third group has a variable absorption chiefly dependent on the amount of water-vapour present.

"Short Wave" Radiation of Solar Origin.—A square centimetre placed outside the atmosphere normal to the sun's rays would receive, according to the extensive researches of Abbot, 1·94 gr.-cal. per minute. The question of natural fluctuations about this mean is still in debate (*vide* the *Monthly Weather Review*, July and Aug. 1925). When the sun is in the zenith of a clear sky a unit of incident energy is divided roughly as follows: 0·78 comes to earth in the direct beam, 0·06 is scattered to space, 0·06 is scattered to earth and 0·10 is absorbed, warming the air. When the sun is nearer the horizon the scattering and absorption are much greater relative to the transmission. Abbot states that clouds reflect about 0·65 of the solar radiation falling upon them. Much further information will be found in the Smithsonian publications, in L. V. King's paper in the *Phil. Trans. Roy. Soc.*, A, vol. 212 (1913), and in recent papers in the *Meteorologische Zeitschrift*. The absorption by ozone is now being studied by Dobson and Harrison (*Quar. Jour. Roy. Meteor. Soc.*, 1925).

Turbulence and Diffusion.—A statement that the wind has a velocity of so many metres per second customarily refers to some mean value taken over say 10 minutes or more. Actually portions of air are moving faster or slower than the mean, as well as up and down and horizontally to and fro across the mean track. These deviations are well shown on the records of pressure-tube anemometers. The wandering portions carry qualities with them. Thus fragments coming from a rapid, damp, hot, smoky current into an adjacent slow, dry, cool, clear layer would bring with them some of the momentum, moisture, potential temperature and dust characteristic of the layer in which the
had previously journeyed. The motion of such fragments is to
intricate to be analysed in detail; but its general effect can b
summed up by a statistical coefficient representing the averag
rate of transfer of the quantities mentioned. The theory o
diffusion, originally worked out by Fourier for the diffusion o
heat in metals, and applied by Fick to the diffusion of salts i
liquids, has been extended to eddy-diffusion in the atmospher
by Åkerblöm, G. I. Taylor (*London Roy. Soc. Phil. Trans.*
A, vol. 215, pp. 1 to 26), Hesselberg and Sverdrup, and W
Schmidt and others.

If χ be the concentration of the dust or other diffusing sub
stance it has become customary to assume that the changes pro
ceed in accordance with an equation of Fick's type such a

$$\frac{\partial\chi}{\partial t}+\bar{u}\frac{\partial\chi}{\partial x}+\bar{v}\frac{\partial\chi}{\partial y}+\bar{w}\frac{\partial\chi}{\partial z}=\mathrm{K}\left(\frac{\partial^2\chi}{\partial x^2}+\frac{\partial^2\chi}{\partial y^2}+\frac{\partial^2\chi}{\partial z^2}\right)$$

where x, y, z, t are rectangular co-ordinates and time; $\bar{u}$, $\bar{v}$ and
are the components of the *mean* velocity, and K is the diffusivit
This view of the process has led to K being observed under
variety of circumstances, by the increase of wind aloft, by th
rate at which water vapour finds its way upward to the cloud
by the scattering of smoke or of balloons or of volcano ash.
has thus become known that K is of the same order of magnitud
whether the diffusing substance be momentum, dust, moistu
or potential-heat. It has further appeared that in the first thre
kilometres K is roughly proportional to the speed of the mea
wind, and is decreased when the static stability of the atmospher
increases. But the variation of K which overwhelms all other
is that dependent on the size of the portion of atmospher
which is observed. Thus if the air is confined to a capillary tub
K is about 0·2 cm.^{2} sec.$^{-1}$, if the portion is a few metres across
is of the order of 10^3, if a few hundred metres K is about 10^5, if
thousand kilometres across K is of the order of 10^{11} in the sam
units (Defant). We may explain this by saying that diffusivit
is a compensation for neglect of detail, and that the amount
compensation increases as the things neglected include in su
cession molecular motion, gusts, squalls and cyclones. In othe
words, the mean-velocity $\bar{u}$, $\bar{v}$ and $\bar{w}$ takes on a new sense whe
ever the size of the portion of the atmosphere under observatio
is enlarged, and this enormously affects K. See a paper by
F. Richardson in the *Roy. Soc. Proc.*, A, 1926.

A vertical gradient of mean wind tends to produce eddies, sta
ical stability tends to damp out eddies. The condition in whic
these effects just balance has been formulated by L. F. Richar
son (*Phil. Mag.*, Jan. 1925). Rayleigh's theory of unstable tem
perature gradients has been brought into meteorology by
Brunt (*Meteor. Magazine*, v. 60, 1925, p. 1).

The Heat Balance of the Atmosphere.—Gold (*Lond. Roy. So*
Proc., A, vol. 82, 1909, and simultaneously Humphreys (*Astr*
phys. Journ., vol. 29, 1909, p. 14) showed that the existence of th
stratosphere could be explained if it were in radiative equilibriu
The discussion as to the atmosphere generally has been continue
by Emden (*Sitz.-ber. d. Akad. Wissensch. Wien*, 1913, p. 55
W. H. Dines (*Quar. Jour. R. Meteor. Soc.*, April 1917), W
Schmidt (*Akad. Wiss., Wien, Mat.-Nat. Kl.*, 127–75, 1918), Chap
man (*Quar. Jour. R. Meteor. Soc.*, April 1925) and others, and h
joined with theories of radiative equilibrium in stars. (See
A. Milne, *Phil. Mag.*, Nov. 1922. It is, however, doubtf
whether the horizontal transport of heat can be neglected
comparison with that in the vertical.

There are seemingly four methods by which an appreciab
vertical flux of heat energy is produced in the atmospher
(1) Convection, which carries heat upwards from the earth's su
face; its action does not extend beyond the first few kilometre
(2) The latent heat set free by the condensation of aqueo
vapour, which carries upwards to the regions where clouds a
formed the solar heat which has evaporated the water from th
sea or wet land surface; this acts in just the same region as co
vection. (3) Radiation, which mostly carries heat upwards fro
a lower to a higher stratum. These three methods present
difficulty, but it must be pointed out that "convection" he

neans local convection, *i.e.*, heat carried by an ascending cur-
ent that is produced by local warmth, not heat carried by an
ir current or by eddy motion due to the general circulation.
This distinction, however, is difficult to maintain, because even
rictional eddies behave as thermodynamic engines. (4) Stirring
y eddies in the wind *i.e.*, turbulence. W. Schmidt has made an
stimate which shows that the amount of heat carried down-
vards across the 2 km.-level in Europe by this cause to be 50 gm.
alories per sq. cm. per day.

An important conclusion follows. Since above the region of
he formation of heavy clouds neither convection nor the supply
f latent heat by condensation is efficacious, the actual lapse-rate
here must represent the balance of two opposing tendencies,
ne radiation, tending toward an isothermal condition, and the
ther mixing, tending to an adiabatic lapse rate.

Dynamics of Wind.—In the upper air it has been shown by
old that the wind velocity approximates to the ideal "geo-
trophic wind" which is imagined as blowing parallel to the
obars with a speed v given by

$$v.2\omega\rho \sin\phi = \partial p/\partial x$$

here ω is the earth's angular speed, ρ is the air density, ϕ is the
titude, p is the pressure, and x is horizontal distance normal
the isobars. In the first kilometre this simplicity is modified
y eddy-viscosity. Elaborate theories on the dynamics of wind
ntinue to develop.[1]

The Meeting of Air-Masses from Different Climates.—Dr. J.
jerknes writes as follows:—

> Cold currents in the temperate zone can be traced back, more or
> ss directly, to polar regions; in winter also to cold continents. On
> eir way they are heated by contact with the ground and become
> istable, provided that no adequate heating takes place in higher
> yers. Polar currents in temperate latitudes therefore frequently
> ve cumulus or even cumulo nimbus with showery weather.
>
> Warm currents in the temperate zone can be traced back to sub-
> pical regions; in summer also to warm continents. On their way
> rthward they are cooled in contact with the ground and become
> ble. If the cooling continues to the dewpoint then stratus clouds
> fogs are formed.
>
> Where cold and warm currents border each other, in typical de-
> essions or elsewhere, precipitation is usually formed. In cases
> ere the warm current gains terrain (warm front) it climbs upwards
> a gently inclined wedge, say 1/100, formed by the underlying cold
> rrent. Impervious cloud-sheets are formed in the climbing warm
> rrent, low clouds close to the warm front and higher clouds farther
> ward. Precipitation is usually falling from the whole extensive
> ud system, but that falling from the higher parts evaporates be-
> e reaching the ground. In cases where the cold current displaces
> warm (cold front) the precipitating clouds are likewise formed in
> rising warm air. The advancing cold wedges are frequently so
> ep that violent ascending motion and correspondingly strong pre-
> itation results. On the other hand, such precipitation is mostly
> nfined to a narrow belt along the cold front.
>
> Extratropical cyclones examined individually show a great variety
> types. Usually the young cyclones consist of two oppositely
> ected currents, one cold occupying a little more than the half of
> area and one warm current covering the remaining area—the
> varm sector." During the development of the cyclone, air from
> warm sector ascends and is replaced at the ground by the cold
> This motion transforms potential energy into kinetic energy,
> ich appears in the increasing winds and deepening of the depression.
> er a couple of days all the air from the original warm sector is
> ed off the ground, but can still be found aloft (occluded cyclone).
> ring the ascension the warm air is cooled adiabatically, and finally
> eaches a level where it finds surrounding air of its own temperature,
> that the buoyancy can lift it no farther. Having reached this
> ge the cyclone is maintained merely by the inertia of the circulat-
> air masses. If no new energy is supplied the cyclone decays grad-
> y.

riginal papers on this subject will be found in Oslo, *Geofys-
Publikationer*, and elsewhere. For the relation between the
rce of air and its temperature see C. K. M. Douglas, *Quart.
r. R. Meteor. Soc.*, July 1925.

ntarctic Meteorology.—Great additions to our knowledge of
meteorology of the Antarctic regions were made by the publi-
on of the results of Scott's Antarctic expedition of 1910 to
2. The observations were taken mostly by Dr. Simpson, who has worked them up and discussed various problems left in a more or less uncertain condition by previous expeditions. He has greatly extended our knowledge both from the observational and theoretical sides. Amongst other matters Dr. Simpson has established the anticyclonic character of the weather in the Ross Sea area, and has shown that the blizzards are not parts of the circulation about the centres of cyclones moving from west to east over the Antarctic Ocean.

New Methods of Observation.—Upper wind was observed during the War (1) at night by pilot balloons carrying candles, (2) by shell bursts observed by two mirrors, (3) by sound-ranging on a balloon that exploded. Subsequently a method has been developed for observing wind above fog by shooting spheres upward. Particulars of such things will be found in the *Computers' Handbook* or the Professional Notes of the Meteorological Office. Clouds can be photographed by moonlight (Oslo, *Geofysiske Publikationer*, vol. 3, No. 12). The amount of water in thin clouds can be measured (*Quart. Jour. Roy. Meteor. Soc.*, Jan. 1925). The upgradient of temperature near the ground can be measured by thermocouples (*Phil. Mag.*, Jan. 1925) and by an optical method (*Quar. Jour. Roy. Meteor. Soc.*, April 1925). Upper air temperature is regularly measured from aeroplanes, and can also be observed by balloons that explode at a prearranged temperature (M.O. Prof. Note 19). For radiation instruments see *Dictionary of Applied Physics*, vol. 3.

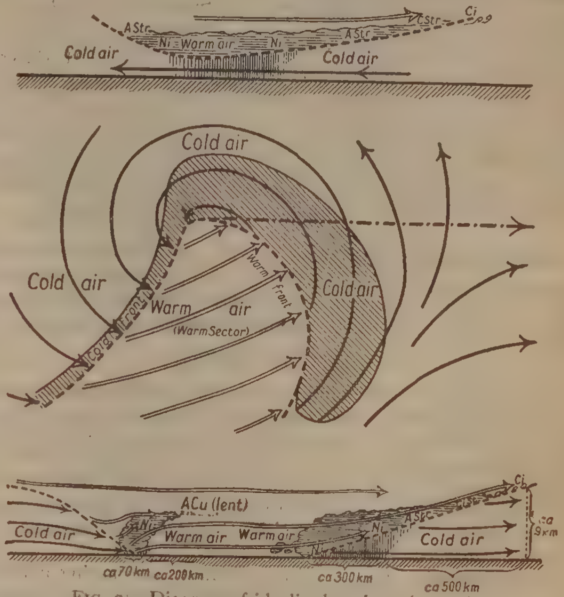

FIG. 2.—Diagram of idealised cyclone (young).

(From "Life Cycle of Cyclones, and the Polar Front Theory of Atmospheric Circulation." J. Bjerknes and H. Solberg, *Geofysiske Publikationer*, Vol. III., No. 1.)

Weather Forecasts.—Forecasts for one or more days ahead continue to be made by the process of drawing a map to represent weather observations received by telegraph from an area some thousands of km. in diameter. The accumulated and classified experience of what usually does follow such a distribution of pressure, temperature, cloud and wind is then employed to form the forecast. The Smithsonian Institution is progressing in its studies looking toward weather forecasts based on solar radiation observations.

Organisations.—The International Meteorological Committee and its subcommissions in 1925 reattained their fully international character, which was destroyed by the War. A post-war restricted organisation known as the International Union for Geodesy and Geophysics has a section for meteorology which is active.

METER: ELECTRIC AND GAS (*see* 18.291).—Meters are used to measure the amount of electricity or gas supplied to the customers of the company concerned. In the case of electric meters these register the number of units supplied for light, heat or power.

I. ELECTRIC METERS

These meters include induction-motor, mercury-motor and commutator meters, which register the revolutions of a disk or other armature caused to revolve, by the action of the current, at a speed proportional to the amperes or watts passing through the meter, and electrolytic meters in which the current or a shunted fraction of it passes through an electrolyte and decomposes it, the rate of decomposition being proportional to the current employed.

Induction-motor Type.—In the Ferranti alternating current watt-hour meter, a series coil of a few turns of thick wire carrying the main current is arranged below, and a shunt coil of many turns of fine wire is arranged above a horizontal rotary disk of aluminium. This disk is situated in the gap between the poles of a permanent magnet and the lower bearing of its vertical spindle is a sapphire carefully selected to reduce friction to a minimum. The magnetic fields due to the shunt and series windings produce a resultant rotating or shifting field which interacts with eddy currents, induced in the disk so as to exert a driving torque proportional to the watts. A retarding torque is produced by the action of the permanent magnet also causing the speed of the disk to be proportional to the watts. A worm on the spindle drives the registering train; the registering dials are of the clock pattern, or of the cyclometer pattern.

To read the meter is a simple operation. In the clock pattern, starting from left to right, the figure last passed by the thousands pointer in its revolution is written down and the same procedure is followed for the hundreds, tens and units pointers in succession, the tenths registered on the small lower dial being read only when testing the meter. In the cyclometer pattern, the figures are written down just as they appear on the register. The cyclometer figure wheels are actuated by a falling weight; thus, the changing of the figure wheels does not throw any extra load on the meter.

Mercury-motor Meters.—In the Chamberlain and Hookham direct current ampère-hour meter, a copper disk is caused, by the action of the current, to rotate in a mercury chamber subject to the influence of a magnetic field due to a large permanent magnet. The vertical spindle of the disk, arranged to rotate with the minimum friction, is connected to the registering train with its series of clock dials. The peripheral wall of the mercury chamber is formed by a leather-lined metal band which is readily removable to permit inspection and refilling with mercury.

Commutator Meters.—Commutator meters have a wound armature connected in parallel with a shunt and arranged to rotate in the field of a permanent magnet.

Electrolytic Meters.—In the Reason syphon-tube meter, a solution of a mercury salt is hermetically sealed in a container, a the top of which are arranged a mercury anode and a cathode During the operation of the meter, mercury is liberated at th cathode and collects in a syphon tube in the container; this tube when full of mercury, discharges into the lower part of the container. Close to the right limb of the syphon tube is a vertica scale which registers the mercury level; in one form of the meter this scale reads from 0 to 200 units. Below the scale is anothe which registers the level of the lower mercury column; this scal may read from 0 to 4,000 units. When reading the meter, bot scales are read and the sum of the readings is taken. The Reaso single-tube meter has one vertical mercury tube, which is rea like a thermometer. In both forms, the mercury can be use repeatedly, the meters being re-set by tilting; the container flexibly mounted to facilitate this operation.

In the Bastian electrolytic meter, acidulated water is decomposed by the action of the current, and the amount of wate decomposed is read off on a vertical scale.

II. GAS METERS

There are two main types of gas meters, viz., wet meters an dry meters. A wet gas meter has a strong iron case containin water, which is normally at a definite level called the "wate line." Inside the case is a rotary drum divided into compartmen and mounted on a horizontal spindle geared to a vertical spind operating the registering train. The drum is rotated by the u balanced elastic pressure of the gas admitted to each compar ment in turn on the surface of the water. After leaving the drun the gas passes to an outlet pipe which delivers it to the burner In order to maintain the level of the water, when loss occu through evaporation or other causes, most wet meters are pr vided with means for automatically making good the loss; the are called compensating meters. In most of them, the water make good the loss is delivered from a water reservoir within t meter case and communicating with the main body of water.

Dry Meters.—In an ordinary dry gas meter, the upper part the meter case forms the registering chamber in which are sit ated the registering train and the valve box, which is sh off from the registering chamber and contains gas inlet a gas outlet valves. The registering chamber is separated by horizontal partition from a lower and larger chamber, which divided by a vertical partition into two equal chambers. In eac of these a bellows of concertina shape, with flexible leather side works to and fro horizontally; the vertical partition forms t fixed base of each bellows. Arrangements of levers and cran transmit the motions of the bellows to the valves in the valve b and also to the registering train. When the meter is in operatio gas from the main supply pipe enters one of the bellows a inflates it, while the gas in the corresponding chamber is expell through a delivery pipe to the burners; at the same time, gas being expelled from the other bellows by the pressure of admitted into its bellows chamber. Working in this way, meter supplies gas continuously to the burners, and the valves the valve box are opened and closed at the proper times requi by the flow of the gas. At the same time the registering train operated continuously.

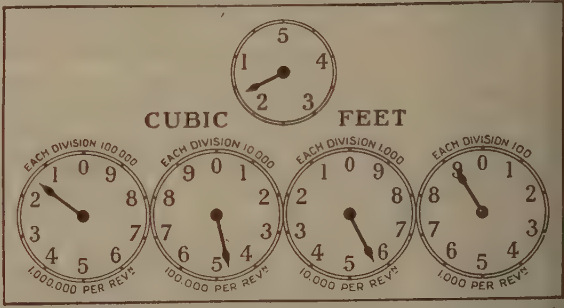

FIG. 1.—Diagram illustrating the registering dials of a 10-lig dry gas meter.

Automatic or Prepayment Meters.—Prepayment gas meters are itted with a box containing mechanism which operates when coin is passed through a slot in the box and controls the supply f gas to the meter. The value of the inserted coin or token letermines the automatic cutting-off of the gas supply.

Reading a gas meter is a simple operation. Fig. 1 represents the egistering dials of a 10-light dry gas meter. The registering train is eared so that the hundreds pointer revolves 10 times while the housands pointer revolves once, the thousands pointer revolves 10 imes while the tens of thousands pointer revolves once, and so on; lso, adjacent pointers revolve in opposite directions. Starting from ight to left, the figure last passed by the hundreds of thousands ointer in its revolution is written down and the same procedure is ollowed for the tens of thousands, the thousands and the hundreds ointers in succession; thus the reading in fig. 1 is 1,459 hundreds. ssuming that this was the reading at Michaelmas and that 1,356 undreds was the reading at the preceding Midsummer, then the mount of gas consumed during the summer quarter would be 45,900 minus 135,600 or 10,300 cubic feet.

The small upper dial is not usually read. It records the flow of nall quantities of gas and can therefore be used for ascertaining hether all pipes and gas fittings are gas-tight, or what amount of as is consumed by any of the burners. (T. E. L.)

METHODISM (*see* 18.293).—The official returns of world-ide Methodism presented to the oecumenical conference at oronto in 1911 showed that there were 55,808 ministers; 98,121 y preachers; 8,768,616 church members; 99,497 churches, orth over 100 million sterling; 90,124 Sunday schools, with 8,722 officers and teachers and 8,273,809 scholars. The de-iled table below shows the position in 1925.

The numerical strength of Methodism is not to be gauged the number of members. To the members must be added a ry large body of communicants and worshippers. About 10% the population of Great Britain are Methodists. In Canada ethodists are 11% of the population; in Australia, 12%; in New Zealand 6%; in South Africa, including Rhodesia, 7%; and in the United States, 20%.

I. IN GREAT BRITAIN

British Methodism has faced with courage and with a large measure of success the new problems of the 20th century. It has consolidated its sections and, in addition to its ordinary routine of work, has given special attention to three great issues—the reunion of Methodism, temperance reform and foreign missionary enterprise.

At least 450,000 officers and men of the Wesleyan, the Primitive, and the United Methodists fought in the World War, of whom 40,000 fell. Methodism cared for its people and materially assisted its members by its war emergency and sustenation funds, for augmenting ministerial allowances and helping circuits suffering from the higher cost of living. In spite of the serious effect which the War has had upon the spending power of the people, the incomes of the Methodist church funds have largely increased. In all the churches the salaries of the ministers have been considerably advanced. There are no unemployed Methodist preachers, and no dearth for candidates for the ministry.

Missions.—The British Foreign Missionary Societies working under the direction of the three Methodist Conferences also have a record of expansion and success. The Wesleyan Missionary Society has erected and equipped 12 colleges with 5,031 students, and also 36 high schools with 6,068 scholars, in addition to 16 theological and normal training institutions for native preachers. Important Medical, agricultural and industrial hospitals and schools have also been established in West Africa, South India and China. These societies work in close co-operation with other branches of Christendom by adopting the apportionment of regions of missionary enterprise. They develop a missionary

spirit among the native Christians and the creation of a native ministry. Thus, there is a large number of native preachers and generous financial support is given to their missions by the native churches. In 1913 the Wesleyan Missionary Society held its centenary and raised £280,000 as a special fund for development. The women's auxiliary of the society has largely increased, and a plan is being developed for realising closer co-operation with the parent society.

Educational and Social.—The decline in the number of Sunday school teachers and scholars has given serious concern to the conferences. Efforts have therefore been made to increase the efficiency and the attractiveness of the Sunday schools, the work of which is not limited to Sunday, nor to school methods. The boy scouts, girl guides and life brigade movements, summer schools and Bible study circles supplement the work of the Sunday schools. The Wesley Guild and Christian Endeavour societies in British Methodism, and the Epworth League in America are doing much to consolidate the work among young people.

The Wesleyan Church has largely transferred its day schools to the county education authorities under the Acts of 1870 and 1902, and has now only 392 day school departments, with 32,847 scholars. But the same Church has largely developed its higher and secondary educational work. The two Wesleyan training colleges for teachers—for men at Westminster and for women at Southlands (Battersea) have attained a very high standard of efficiency. An increasing number of the students take university degrees. The teachers thus trained hold many of the most important posts as headmasters and mistresses in the London and provincial day and secondary schools and also in the British Dominions.

In addition to a number of important educational institutions, the three British Methodist Churches have six theological colleges for training candidates for the ministry, which are being more and more brought into line with the curriculum of the various universities. In 1926 Oxford celebrated the bi-centenary of the election of John Wesley to a fellowship of Lincoln College, and, to honour the occasion, conferred the degree of Doctor of Divinity upon the Rev. John H. Ritson, the president of the mother conference, a scholar and graduate of Balliol College, and the first Oxford man elected to the chair of John Wesley.

Another department of British Methodism is its home missionary work in the villages and city centres. Wesleyan Methodism has its connectional and lay evangelists. Open air evangelistic services are regularly held, and in many places the theatres and public halls are utilised for extra services. New central halls take the place of down-town churches. The London Mission of Wesleyan Methodism is doing a great work at Westminster, Kingsway, Clerkenwell and other centres. Primitive Methodists have four halls in the poorest parts of London, the principal ones being in Whitechapel and Southwark.

The British Methodist churches have been impressed with the economic and social results which have followed prohibition (*q.v.*) in the United States. Each of the sections has an active temperance and social welfare department. In 1920 the Wesleyan Conference declared that the sale of intoxicating liquors as a beverage was "definitely opposed to the best interests of the State and to the Kingdom of God," and recommended the Methodists everywhere to work and pray for the total and permanent prohibition of the common manufacture and sale of alcoholic drinks. The three Churches have adopted a progressive temperance policy—first of local option, secondly, the complete extension of magisterial licensing authority to all political and social clubs, rich and poor alike; and, thirdly, the entire Sunday closing of all drinking bars in England and Wales.

The Methodist Brotherhood works in unison with the Dominion agents in London, who assist emigrants to the United States, Canada, Australia and South Africa, arrange their passages, and secure them employment. The Brotherhood embraces all Methodist churches, and it has met with conspicuous success in assisting the Methodist emigrant and maintaining his association with Methodism in his new country.

Methodist Union.—Methodist union transcends in importanc all other movements in Methodism at the present time, and it i probably fraught with more momentous issues to the churche concerned than anything since the death of Wesley. A grea impetus was given to this movement by the decennial gathering of the Methodist Oecumenical Conference, which, instituted i 1881, meets alternately in London and America. It consists 600 delegates from all parts of the world, half of whom ar ministers and half laymen. Each assembly has been followe by some decisive step forward along the path of union, and i all cases the ministry has loyally accepted the decisions of th majority. The results of union have far exceeded the antic pations of the churches, and there has been a great increase i the membership and financial resources.

In 1913, the Wesleyan Methodist Conference appointed committee to collect information on the subject of union and t report to the next Conference. A final scheme of union was su mitted to the yearly conferences of the three Churches in 192 and was adopted by a very large majority. The scheme, whic has presented no serious difficulties, will be again presented t the three conferences of 1926 together with the drafts of th proposed Parliamentary Enabling Act of Union and of th proposed Chapel Model Deed of the new United Methodis Church of Great Britain. If these are approved an applicatio will be made to Parliament, and there is every prospect of th union of the three Churches in one British Methodist Churc being effected in 1928.

II. IN AMERICA

The noteworthy changes in American Methodism since 19 include (1) the steady growth of all its major branches; (movements toward the organic union of various units with the Methodist group and with other evangelical churches; ar (3) educational advances resulting in liberalising tendencies theology, a higher appreciation of non-Christian religious grou with a consequent new approach to the problem of wor evangelisation, the further democratisation of Episcopal Meth dist Churches and an increasing zeal for social justice, inte racial understanding and the application of the teachings Jesus to all human relationships and affairs, in politics and s ciology as well as to purely personal conduct and belief.

Church Union.—The year 1925 saw the consummation the Union of the Methodist, Presbyterian and Congregation Churches of Canada in the United Church of Canada. The Met odist Church, as the largest of the three denominational uni went into the United Church with 100% of its constituency, whi at the time of the merger included 2,475 ministers, 1,946 l preachers, 414,047 members, 451,636 church-school pupils, wi 43,333 officers and teachers. In the United States a plan for t organic reunion of the Methodist Episcopal Church and t Methodist Episcopal Church South failed (1925) by a narr margin of the combined votes of lay and ministerial membe of the southern church. The vote in the Methodist Episcop Church at the same time was overwhelmingly in favour of t union. The vote of the Methodist Episcopal Church Sout while rejecting the specific plan submitted, did not close t issue, which was to be considered again at the next session of t respective General Conferences of the two bodies. In Gre Britain the union of the Wesleyan Methodists, the Primiti Methodists and the United Methodist Church was also neari its consummation.

Educational Advances.—The educational advances to which nust be attributed certain tendencies already summarised nclude the following (1) an increase, commensurate with the rowth in church membership of, in the number, enrolment and nancial support of secondary schools and colleges; (2) a rapid ise, especially in the United States, from the previous low aver- ge educational preparation and professional training of minis- ers, together with a corresponding advance in the curriculum tandards for collegiate and theological institutions; (3) in- reasing attention to religious education through the church- chool with the extension of the programme of religious educa- on to include week-day instruction; (4) the widespread distri- ution and use of religious-educational literature in text-book nd periodical form, the total regular circulation of which xceeds the combined total membership of all Methodist hurches.

Episcopal Methodist Churches.—The coloured Methodist piscopal Church, an offshoot from the Methodist Episcopal hurch South, leads all branches of Episcopal Methodism with creases of over 60% in membership and over 100% in church- hool enrolment in 15 years. The Methodist Episcopal Church 1916 adopted the Episcopal area system with a flexible limit the residence of a bishop in any one area. A World Service ommission since 1924 acts as an overhead co-ordinating agency r all benevolent boards. The educational activities of the hurch have been consolidated in one board of education with parate departments for colleges, negro education, church- hools and the Epworth League. During 1920–5 the centenary the organisation of the foreign missionary enterprise was ebrated by Episcopal Methodist Churches, notably the ethodist Episcopal Church and the Methodist Episcopal urch South, by a five-year financial campaign, which has adrupled the annual missionary offerings of the participating urches.

METROLOGY: *see* MEASUREMENTS.

MEUSE-ARGONNE: *see* VICTORY, ADVANCE TO.

MEXICO (*see* 18.317), a federal republic of North America, has area of 767,198 square miles. In 1912 the estimated population s 15,501,684, of which about 20% were whites. Political disturb- es have resulted in a movement towards the cities for safety, across the frontiers for employment and political asylum. s is reflected in the 1921 census, which gave a population of 234,852. The population of Mexico City, the federal capital, 633,367; Guadalajara, 110,468; Puebla, 96,121; San Luis osí, 85,000; Monterey, 85,000; Vera Cruz, 48,633.

I. POLITICAL HISTORY

n Sept. 27 1910 Porfirio Diaz was re-elected president for a enth term. The closing years of his rule were marked by nomic depression, crop failures, excessive importation of lstuffs and political restlessness, ill-concealed by the festivi- of the Centennial of Independence. Since 1908 various tical activities had indicated a demand for a change in the idential office. Conspicuous in this demand was Francisco Madero, who supported a nationalistic programme. His *sion presidencial en 1910* attacked the administration mildly; as his adherents increased in number, he became more out- ten. He was arrested on charges of sedition and was im- oned at San Luis Potosí. Escaping to San Antonio, Texas, ssued the *Plano de San Luis Potosí* demanding electoral re- s, division of agrarian property and the resignation of Diaz. rmed revolt was planned for Nov. 20 1910, but there were erous premature outbreaks. Against these a reign of terror initiated, but resistance spread. By Dec. there was armed lt in a dozen states. Diaz attempted to meet disaffection by nises and belated reforms. After minor reverses the northern s took Ciudad Juarez May 10 1911, thereby showing the ary impotence of Diaz. This success, with others at Pachuca Cuernavaca, induced Diaz to assent to the demand for his resignation. It was agreed that Francisco de la Barra should assume a provisional presidency and call a new election. Diaz resigned May 25, and left the country next day. On June 7 Madero entered Mexico City in triumph. He really controlled the country, De la Barra having scant power. The ensuing election resulted in an overwhelming majority for Madero, who was inaugurated as president on Nov. 6 for a term to end Nov. 30 1916. He soon found himself opposed by reactionary politicians, several of whom he had appointed to his Cabinet. His government was characterised by neglect of the demands of the revolution, by financial blunders, by quarrels with State governors, and by weakness towards the opposition. Revolt by former supporters began at the time of his inauguration. Emiliano Zapatas in Morelos, Bernardo Reyes in the north, Pascual Orozco in Chihuahua, and other rebels were in the field. In the fighting, many foreigners were killed. Conditions were chaotic in 1912. On March 14 President Taft prohibited shipment of arms to Madero's opponents. Americans, advised to leave the country, departed by thousands. The north generally was in anti-Government hands.

Huerta Seizes Executive Power.—On Oct. 12 Felix Diaz revolted in Vera Cruz; he was captured and was confined in Mexico City. On Feb. 9 1913 he and Reyes (who also had been imprisoned) were set free by disaffected soldiers. Gen. Victoriano Huerta, head of the Government troops, turned traitor and imprisoned Madero and Pino Suarez, forcing them to resign. Huerta on Feb. 19 seized the executive power through constitutional forms. Three days later Madero and Pino Suarez were executed. President Wilson rebuffed Huerta's efforts to obtain recognition, believing that he did not represent the will of the people, and that he was responsible for the political executions; President Wilson demanded a general election in which Huerta should not be a candidate. The demand was rejected. On Oct. 10 Huerta seized the legislative and judicial power, arresting 110 members of Congress for inquiring into the mysterious death of Senator Belisario Domingues, who had harshly criticised him.

Meantime revolt, led by Governor Venustiano Carranza of Coahuila, appeared in both the north and the south. In the *Plano de Guadalupe* the rebels declared Huerta a usurper. They won numerous successes, among them the capture of Torreon in March 1914. Following the outbreak of revolution, American war vessels had been observing events in Mexican harbours. At Tampico a boat's crew from the "Dolphin" were arrested on a military reserve. The American commander demanded a salute to his flag for the incident and was supported by President Wilson. Huerta refused unless the Mexican flag were similarly saluted, and the Americans seized Vera Cruz on April 21. Huerta had been embarrassed by the mission of John Lind, whom Wilson sent as a personal representative to induce Huerta to assent to his own elimination. Though unable to effect foreign loans or to make peace with the Carranzistas, and in spite of advice by the foreign diplomats to yield to Wilson, Huerta ended diplomatic relations with the United States on April 22. Argentina, Brazil and Chile proffered their good offices; representatives of these nations met representatives of Huerta and the United States (Carranza holding aloof) in conferences at Niagara Falls, Canada, but the representatives failed to agree on a provisional president. Huerta was finally forced to resign July 15 1914, and was succeeded by Francisco Carbajal, who held office less than a month.

Carranza, though he did not support the Zapata programme, and quarrelled with Villa, still headed the Constitutionalists; after obtaining control of the capital, he set in motion plans for a presidential election. He was unable to control the generals summoned to a nominating convention, and they moved from Mexico City to Aguascalientes, where they nominated Gen. Gutierrez, an adherent of Villa, as provisional president. Villa drove Carranza out of the capital, the latter occupying Vera Cruz as the Americans evacuated that port Nov. 23. Villa and Zapata alternated in control of Mexico City and no fewer than four factions claimed the executive power in 1915. In that year Villa, who had shown strength in the north, was defeated by

Gen. A. Obregon. A conference of Argentina, Brazil, Chile and other American Powers, seeking to stabilise the situation on Oct. 19, recognised Carranza as *de facto* president.

Villistas Murder Americans.—Villa ignored the settlement, and on Jan. 10 1916 a band of his adherents assassinated 18 Americans taken from a train near Santa Ysabel. On March 9 he raided Columbus, N.M., killing 17 Americans. A punitive expedition of 12,000 United States troops, led by Gen. Pershing, invaded Mexico. It penetrated to the vicinity of Parral, but failed to capture Villa, who was reported dead. Carranza had grudgingly acquiesced in the invasion, but now protested, stating that the movement of American troops in any direction other than northward would provoke attack. On June 20 American negro cavalrymen moving eastward were attacked at Carrizal; several were killed and about a score were captured, but were released upon a sharp demand by the United States. The expedition was finally withdrawn Feb. 5 1917. In Sept. a commission attempted to make an agreement for policing the international line, but failed because Carranza denied the right of the United States to pursue raiders into Mexican territory.

In 1917 a new constitution was proclaimed. It incorporated in Art. 27 the principle of nationalisation of subsoil resources, chiefly as a means of controlling the petroleum industry. Decrees attempting to force the oil companies to observe the constitution were protested by foreign powers as confiscatory and subversive of rights acquired under the prior constitution of 1857. During 1919 the controversy was bitter. The companies, threatening cessation of production, forced Carranza in Jan. 1920 to concede the privilege of operating without compliance with the decrees but without prejudice to the final adjudication of the difficulty.

During 1919 rebel activities against Carranza were widespread, and many acts of violence were committed against foreigners and Mexicans by both Government and rebel partisans. A conspicuous case was the abduction for ransom of W. O. Jenkins, U.S. consular agent at Puebla, Oct. 19. He was alleged by the Mexican Govt. to have been implicated in his own abduction, but was released Dec. 5 1920. During the World War Mexico's "rigid neutrality" was highly pro-German. The famous Zimmermann note, by which Germany tried to align Japan and Mexico against the United States, was intercepted and published in March 1917.

Obregon Elected President.—The presidential campaign began in 1919, Carranza's power then reaching its zenith and afterwards rapidly declining. There was corruption in the army, banditry throughout the country and non-enforcement of the constitution Amid widespread unrest two generals, A. Obregon and P. Gonzales, conducted presidential campaigns, while Carranza supported a civilian candidate I. Bonillas, who had been Mexican minister to Washington. When Carranza's efforts to control state administration for the election of Bonillas led him to attempt a military invasion of Sonora, the home of Obregon, armed revolt broke out. On April 9 that State declared its secession until it could be assured of its sovereignty. The defection spread quickly through the north and west. By the end of the month Carranza was isolated in Mexico City. Adolfo de la Huerta was set up by the rebels as provisional president. Carranza attempted to move his Government to Vera Cruz, but his trains were broken up, and when he left them to make his way over the mountains to a Gulf port, he was murdered on May 21 at Tlaxcalantongo. Obregon entered the capital May 8. On May 25 de la Huerta was made substitute president for the unexpired term by the reassembled Congress. In Sept. Obregon was elected president with only nominal opposition. His inauguration Dec. 1 1920 was attended by large delegations from the United States, but by no one representing the Government though many Latin-American and European diplomats were present. Recognition by the United States was delayed by the non-solution of the petroleum controversy and the general spirit of labour unrest.

The distinguishing features of Obregon's presidency were his efforts to obtain recognition and to carry out the revolutionary programme. The two policies were in direct antagonism at many points. The Association for the Protection of American Rights in Mexico demanded that American vested interests, menaced by the new constitution and subsidiary legislation, be protecte by a special treaty. The demand was grounded on the realisatio that congressional legislation was subject to reversal and tha the decisions of the Supreme Court were more in accordance wit political exigency than with the principles of jurisprudence The Obregon Govt. remained firm in its determination to d everything compatible with national integrity to restore harmonious relations, but refused to enter into the proposed treaty In pursuance of this policy Obregon on July 13 1921 invited th European nations having claims against Mexico to send representatives to a permanent Mexican Claims Commission. Thi invitation was accepted in Nov. by France, Great Britain, Italy Spain and the Netherlands. In Sept. of the same year negotiations were begun with a committee of international banker looking toward a refunding of the national debt.

In June 1921 the U.S. Secretary of State (Hughes) describe the fundamental issue as resting on a construction of the confiscatory enactments, which would declare that recognise American property titles must not be invalidated. The decisio of the Mexican Supreme Court in 1922 that Art. 27 was not to b construed retroactively, paved the way for a presidential decre to the same effect. Secretary Hughes announced an informa commission composed of Charles B. Warren and John B. Payn to confer with Ramon Ross and Fernando Gonzales Roa concerning agreements preliminary to recognition. The conference begun May 14 1923, were facilitated by promulgation, on Apr 26 preceding, of a new petroleum law recognising the validit of concessions made prior to May 1 1917, although it require concessionaires to revalidate their claims within three year Elimination of land difficulties was attempted by legislatio increasing the size of individual holdings exempt from partitio and relieving from expropriation large irrigation companies wit colonisation contracts. But the provision that land expropriate should be paid for in bonds threatened a deadlock. The Mexica position was weak on this point, as the old legislation ha prescribed compensation prior to expropriation.

Despite all difficulties, however, the commission reached final agreement on Aug. 15. By its terms subsoil mineral righ acquired and developed before May 1 1917 were recognised valid, and the provisions of Art. 27 of the Mexican Constitutio it was agreed, should apply only to later acquisitions. Americ properties expropriated by the Mexican Govt. in carrying o its agrarian policy were to be paid for at their equitable valu The U.S. Govt. reserved all rights to which it was entitled und international law in respect of titles acquired by its nationa before May 1917 to properties which were supposed to petroleum yielding but which had not been developed a proved. Provision was also made for a Special Claims Co mission for the settlement of American claims created since 191 and a General Claims Commission for settlement of Americ and Mexican claims since 1868. The conventions calling for the commissions were ratified in Feb. 1924. The special commissi was composed of Ernest B. Perry, Fernando Gonzales Roa a Dr. Rodrigo Octavio of Brazil, and the general commission Nathan L. Miller, Aquiles Elurduy and Dr. Cornelis v Vollenhoven of Holland. The special commission held prelimina meetings in Mexico City in Jan. 1925, but postponed regular s sions until September. Claims must be presented before it with two years from the date of its first meeting, with a possible gra of six months. The general commission held preliminary meeti in Washington in 1924. Claims were admissible before it with one year, with six months' possible grace. Following the agr ment upon these conventions, the United States extended for recognition to Mexico, Aug. 31 1923. France shortly follow suit, Great Britain showing reluctance because of the indefi status of her oil interests.

Papal Delegate Expelled.—The general plan for refunding Mexican debt, agreed upon in Paris in April 1922, was c cluded in New York in May by Secretary of the Treasury Ad de la Huerta and the bankers' committee. Mexican reb headed by Felix Diaz, made unavailing efforts to prevent c summation of the debt agreement. Mexico assumed full obli

ion for all the foreign debt principal, about $500,000,000, for
ome $200,000,000 interest, and for certain internal debts held
utside Mexico. Payments were to begin Jan. 2 1923.

The bandit Villa, who had been bought off by the Provisional
ovt. in 1920, was assassinated in 1923. Another outstanding
ncident of the year was the expulsion of the papal delegate Mgr.
ilippi, who had incurred the displeasure of the Government by
ssisting at the open-air dedication of a shrine at Cubilete
uanajuato. Open-air religious exercises were prohibited by a
tate law, though the dedication took place on private property.
he episode evoked protest from the Vatican and from Catholic
ocieties throughout Mexico and the American continent.

Preliminary manoeuvring in anticipation of the presidential
lection set for July 6 1924 began in 1923. The president is con-
itutionally barred from succeeding himself, and there had been
“ gentlemen's agreement ” by the Sonora triumvirate, de la
uerta, Obregon and Calles, that Calles should succeed Obregon.
evertheless there was decided opposition to this programme in
e Co-operatist party, which had been formed by the triumvir-
te and had a majority in the Chamber of Deputies. On Sept.
4 de la Huerta, possessing wide prestige because of the success
his financial negotiations, resigned from the Cabinet to conduct
campaign on his own behalf. Meanwhile Calles, as the friend
Obregon, was canvassing for the Co-operatist nomination.
his, however, went to de la Huerta, on a programme promising
e extension of Co-operatist ideas in industry, prior indemnifica-
on of landholders for expropriations, and guarantees of munici-
l autonomy. Calles, disappointed at not receiving the Co-
eratist nomination, was put forward by the radical National
grarians, pledged to carry out their programme and protect
e rights of labour. The campaign became exciting when
bregon and the new Minister of Finance, Alberto Pani, accused
la Huerta of extravagance in office and of misrepresentation
ncerning arrangements whereby a bank of issue was to have
en created and a loan secured. Recriminations were mutual.
he de la Huerta faction alleged that Co-operatist adherents in
ongress were menaced with massacre by troops under Gen.
nulfo Gomez. Meantime the state elections, coloured by the
tional campaign, caused numerous frays.

On Dec. 5 the de la Huerta movement resorted to a plan of
mpaign called the *Plano de Vera Cruz*. The military forces of
e States rebelled under the leadership of generals Estrada and
adalupe Sanchez. At least six additional States speedily
ned the movement, the conservative elements, the labourites
d the agrarians generally supporting de la Huerta. Obregon
k the field, conducting a campaign on three fronts. Rebel
ccesses soon showed that the Government was in a precarious
ndition. Its chief weakness was lack of war materials, of which
exico produces none. Application was made to the U.S.
vt. for the purchase of arms, munitions, airplanes and war
ssels. Arms, munitions and airplanes were supplied. President
olidge by proclamation forbade export of arms to the rebels,
d their attempts at blockading and mining ports were in Jan.
25 forbidden under threats of naval action. American as-
tance thus turned the tide. During the closing days of Dec.
vernment forces had retaken Puebla and driven back the
position lines which had been concentrating on the capital.
ring Jan. honours were even, but in Feb. large hostile areas
re retaken by the Government. Several rebel armies dispersed
d their leaders sought refuge in exile.

The direct intervention of the United States was given in
s case because of the recent recognition and a desire to protect
visible agency of the international agreements. The stand
the American Govt. was justified by Secretary Hughes on the
und that it protected constitutional procedure; he added that
must not be held to constitute a precedent, as every instance
intervention must be decided by its individual circumstances.
was in all essential aspects a continuation of the policy initiated
Woodrow Wilson in 1913. The Aguila (British) oil interests
re accused by Obregon of assisting de la Huerta; on the other
d, E. L. Doheny, an American oil prospector, announced
t he had advanced a loan of $5,000,000 to Obregon.

Election of Calles.—In the presidential elections Calles emerged successful. His Conservative opponent, Gen. Angel Flores, who fell ill during the campaign, received relatively few votes. Rumours of his prospective rebellion were not realised. The announced programme of Calles was to obtain for Mexico the economic and social advantages enjoyed by the American people. From the time of the inauguration of Obregon the labour situation had been steadily growing worse, but a firmer attitude toward labour was seen when Calles federalised the railway service, reducing the likelihood of strikes. Recurrent street railway strikes in Mexico City had marked the rule of Obregon; the first of them to occur under the presidency of Calles demonstrated the precarious position of capital under the existing strike legislation.

During the spring of 1925 Calles ruled illegal a strike by the Tampico Federation of Labour Unions, whose members were employed by the Huasteca Petroleum Co., because the difficulty was between unions, not between employers and labour. Firm presidential action prevented a national sympathetic strike. The Union of Bank Clerks in May 1925 made such demands on the banks that they threatened to close their doors. The Labour leader, Luis Morones, refused to support the Union. The Labour party under the leadership of Morones definitely split with the Agrarian party in May because the Labourites declared that the Agrarian programme was injuring not only agriculture but business and industry as well, and hence the labouring people.

Church and State.—The hostility to the Roman Catholic Church became evident with the promulgation of the constitution of 1917. During 1925 a separatist movement by means of an organisation known as the Mexican Apostolic Church was attempted. During March Separatists and Catholics came into conflict in Guadalajara, Aguascalientes and Queretaro. In Mexico City the Separatists seized the church of La Soledad and ejected its priest. Calles declared the act unconstitutional, but closed the church to worship and declared the Catholic parishioners rebels. Foreign priests were debarred, March 19, from preaching in Mexican churches. Numerous churches were closed because of disorders. The constitution provided that ministers practising religion must be of Mexican birth, and limited the parishioners of each to 1,000.

The troubles between church and state were accentuated by events in 1926. On May 15, George Caruana, the papal delegate, was ordered to leave the country, and on July 3, the Government issued a decree to enforce and strengthen the orders against the clericals. Heavy penalties were specified for any infringement of the regulations. Many Roman Catholics declared their intention to resist and Pope Pius XI. declared Aug. 1 1926 as a day of prayer for intervention in Mexican affairs.

Conditions on the American border, never satisfactory, grew worse after the passage of the law limiting immigration into the United States. In May 1925 a treaty was negotiated covering smuggling of drugs and aliens, migration, deportation, hunting, fishing, and health problems. The terms facilitated the disposal of American undesirables who had infested the Mexican side of the boundary. The treaty controlled also the movement of labourers into the United States. It was estimated that 500,000 Mexicans entered California in 1924.

Public interest was aroused in June by the declaration of Secretary of State Kellogg, made public through the Press, that conditions in Mexico were not entirely satisfactory, and that the United States would support the Government of Mexico only so long as it protected American lives and rights and complied with its international obligations. The statement referred to seizures of American property at the unreasonable demand of Labourites, and was felt in some quarters to have been inspired by friends of Calles himself in order to strengthen his hand against the demands of his radical supporters. The unusual character of this announcement called to public attention the existence of a new treaty between Japan and Mexico which permits settlement of Japanese from California on the west Mexican coast, and concedes special status to Japanese vessels in Mexican waters. It also accentuated the fact that American diplomatic protests concerning land seizures had met with scant attention.

On Aug. 28 1925 relations with Great Britain, severed because of difficulties culminating in the assassination near Puebla of Mrs. Rosalie Evans, were resumed and accredited representatives were exchanged.

Defence.—Military service in the active army or in the National Guard is compulsory. The normal strength of the army has been settled at 50,000. A school for the training of aviators has been established and progress has been made towards organising an air force. The five gunboats, which comprised the Mexican navy, have been reinforced by the addition of a small coastal defence boat bought in 1924.

Education.—Government education in Mexico is compulsory and secular. In 1923 there were 14,231 primary schools with 1,187,407 pupils. A number of private schools conducted by religious societies of the Roman Catholic Church were obliged to close in 1926. In 1925 the National University in Mexico City, which was refounded in 1910, had a student body of more than 6,000. The expenditure on education in 1923 was $24,500,000.

II. ECONOMIC AND FINANCIAL HISTORY

Finance.—On July 1 1922 the public debt of 1,056,973,713 pesos (1 gold peso = $0.4985) included 583,280,887 pesos of pre-revolutionary debt and 473,692,826 pesos of post-revolutionary debt. Revenues and expenditures 1921–5 were, in pesos:—

	Revenues	Expenditures
1925	145,000,000[1]	143,199,686[1]
1924	289,959,500[1]	(2)
1923	278,110,300[1]	347,006,719[1]
1922	277,567,019	267,137,468
1921	279,832,932	258,312,774

[1] Estimated.

[2] No estimates of 1924 expenditures were published. The Federal Govt. derives its largest income, outside of petroleum production and mining, from import duties: second in importance is the stamp tax: and third, taxes collected in the Federal district and territories. The income tax was introduced in 1924 in face of marked and widespread opposition.

Production and Industry.—Mexico possesses 30,027,500 ac. of cultivated lands well suited for agriculture. The agrarian reforms, begun in 1915, whereby lands of large estates have been expropriated are responsible for a noticeable decrease in agricultural production. In April 1925 President Calles reaffirmed his campaign pronouncements on the agrarian and labour problems, asserting that land distribution would be continued legally, but that it must not move in advance of means of development. In Aug. 1925 it was announced that one-third of the Government's land division programme had been fulfilled. It was estimated that since 1915, 12,000,000 ac. had been given to small farmers. The grazing lands of the republic are estimated at 120,444,200 ac.; and forest lands at 43,933,200 acres. Estimates of chief crops of 1924 were: corn (maize), 106,293,000 bu.; wheat, 13,962,000 bu.; raw cane sugar, 186,964 short tons; cotton, 138,000 bales (of 478 lb. net). Other important crops are beans, coffee, tobacco and henequen. The census of 1923 showed livestock as follows: horses, 512,336 valued at $20,455,109; mules, 300,960, valued at $18,713,476; cattle, 2,363,427, valued at $95,622,494; sheep, 1,196,098, valued at $5,777,605; goats, 2,106,044, valued at $7,714,330. The decrease in livestock since the enumeration of 1902 was 60%.

Petroleum.—A new petroleum law, published July 20 1925, was pending before Congress during September. It had received presidential sanction as adequately interpretative of Art. 27 of the constitution. It gives the chief executive sole and complete authority to concede and regulate rights to explore for and exploit oil-fields; it confirms leases and concessions as well as titles perfected, if dated prior to May 1 1917. The petroleum industry is defined as a public utility, and the principle is reasserted that the nation exercises direct and permanent ownership of the subsoil.

The total production of petroleum from 1901–23 inclusive was 1,055,257,562 barrels valued at $828,241,710. The peak of production, attained in 1921, was 193,397,587 barrels, about 28% of the world production and worth $182,936,817. In 1922 ther were produced 182,278,457 barrels, about 21% of the worl production, worth $167,397,872; in 1923, 149,529,088 barre worth $142,916,885, 14·7% of the world production; in 192 139,587,000 barrels, 13·8% of the world total. In 1923 Mexica production was second to that of the United States. Som 15,000 ac. were under exploitation. In May 1925 it was est mated that foreign investments in petroleum concerns totalle $350,000,000. Consistent progress was made in the exploitatio of the petroleum-bearing areas, which are known to be mor widely distributed than the present development would indicat During the first 10 months of 1924, 247 new producing wells wer brought in with an initial daily production of over 800,000 ba rels. At the end of Oct. 1924 there were 1,016 producing well their initial daily production running more than 3,344,00 barrels. Most of the producing wells were in the Panuco field From Jan. 1 to March 25 1925 new wells numbered 74; the maximum daily production was 364,367 barrels, exceeding th amount produced by new wells during the first three months 1924, which was 218,596 barrels. In March 1925 the petroleu companies agreed to an added tax of one cent per gallon on ga olene the proceeds from which, estimated at 8,000 pesos daily, a being applied to road construction.

Production of light and heavy crude oils for the first six month of 1925, totalling 65,369,987 barrels showed a decrease of 8,911 376 barrels from the corresponding period in 1924. All the lo was in heavy crude oil, the light crude oil showing an increas of 2,145,172 barrels. Continued salt-water intrusion in the Totec holding of the Mexican Seaboard diminished their productio in 1925; salt water also reduced production in the Cacalila fields.

Mining.—There was marked resumption of mineral productio in 1918 and 1919. Practically all the established mining com panies operated continuously during 1924, some of them extend ing mining and milling facilities so as to increase production an improve metallurgical recoveries. Prospecting and developmen work increased, notably in Chihuahua, Sonora and Zacateca The de la Huerta revolt did not seriously interfere with th operation of established mines. Taxation continued upon th 1923 basis, being so high that the average mine paid as much i taxes as it produced in net profit. Freight rates were approx mately 50% higher than those of 10 years earlier. Labou conditions were chaotic because of numerous State laws, an caused much misunderstanding between companies and em ployees. These conditions discouraged new mining investment but good prices for lead and silver offset them, and earnings fo 1924 were good. Productions of the chief minerals for 1922– was (in kgm.):—

	1924	1923	1922
Gold	24,647	24,162	23,276
Silver	2,844,104	2,824,599	2,521,832
Copper	49,113,194	53,371,482	26,977,786
Lead	164,140,130	155,720,342	110,455,912
Zinc	18,936,336	18,481,271	6,141,937

Antimony, tin, tungsten and arsenic are produced in conside able quantities. For the first time in several years quicksilve was exported in June 1925; there was promise of continuou increase. The movement was of 600 kilos shipped from Tampic and produced by a cinnabar mine in Zacatecas. Numerous filing of claims in Chihuahua for gold and silver locations, reopening old workings in the Santa Barbara district of that State, and th development of electrical power in Durango for mine operation indicated in 1926 that mining prospects continued good, in spit of the political unrest.

Commerce and Industry.—Notwithstanding political an economic difficulties, trade showed gratifying stability. Mexic sold to the United States in the first 10 months of 1924 product to the value of $167,087,305, or 19·2% over the figures for 192 and bought from the same source goods worth $135,076,703, a increase of the same percentage. Increased production of lea copper and silver, with greater shipment of vegetables to Amer can winter markets, permitted purchase of larger quantities of utomotive vehicles, agricultural implements, mining machinery nd railway equipment.

For the year ending June 30 1913 Mexican imports were 95,857,000, and exports $149,752,000. For 1921 they were espectively $178,775,221 and $203,273,450. Imports from the Jnited States in 1921 were 74·6% of the total, and exports to he United States 88·3%. In 1923 Mexican exports of all classes vere: animal products, $2,019,486; vegetable products, $32,782,-61; minerals except petroleum, $80,213,217; petroleum $237,-13,698; miscellaneous, $2,109,872. Petroleum constituted 67% f the total exports. Minerals reached 22·5%, constituting with etroleum 89·5% of the 1923 exports. Agricultural exports to he United States were 14% of the trade with that country, etroleum 38% and other mineral products 45%. Canadian xports to Mexico were in 1920, $410,825; in 1921, $1,086,197; n 1922, $1,197,597, and in 1923, $3,291,098, and in the year nding March 31 1925, $2,856,409. Imports from Great Britain, igh in 1920 and 1921, dropped to pre-War level in 1922–3. The novement of trade has been steadily away from the Gulf ports owards towns on the American border, which in 1923 handled ver 42% of the volume. There were 108 mills operating, em-loying 38,232 hands. The annual production of boots and shoes vas over 700,000 pairs. In 1923, 235 sugar-mills produced 121,000 netric tons.

Labour.—Conditions in labour have been disturbed since the volution began. Strikes and financial losses have been as llows:—

	No. of Strikes	No. of Strikers	Financial Loss	
			To Employers	To Employees
1922	197	63,000	$4,134,680	$2,983,610
1923	146	54,396	3,694,324	1,479,055
1924	138	29,244	4,627,385	1,805,191

abour troubles at Vera Cruz caused the chambers of commerce transfer their business to Tampico in Nov. 1924. In March 25 a federation of land and sea workers, comprising 17 Vera uz unions affiliated with the Mexican Federation of Labour, ve up political activities and agreed not to strike without deration approval.

Communications.—In the de la Huerta revolt the railways in bel hands were badly depleted in stock. In March 1924 an icial report of the ownership of railways showed that the ational Railways (51% of whose stock is held by the Govern-ent) had 13,205 km.; Government railways, 517 km.; private es 7,529 kilometres. The total in operation was 21,251 km. 13,197 miles. The Mexican Railway, a British concern, has m. between Mexico City and Vera Cruz; it was in Government nds from 1916–20. The Tepic-La Quemada line of the Southern cific was completed April 1926. It connects Mexico City with gales. During 1925, 45,000 men were employed on the 100 m. the road, 17 tunnels having been constructed before June. e new wireless station erected on the Island of Lobis, near the ast of Tampico, affords facilities to the petroleum companies to nmunicate with ships at sea. There are wireless stations at exico City, Tampico, Vera Cruz and on the Pacific Coast at azatlan.

(H. I. P.)

MEXICO CITY, capital and metropolis of the Republic of Mexico (*see* 18.344), had a population of 615,367 at the census of 1920 (271,956 males and 343,411 females) of whom 23,668 were foreign-born; estimate for 1924, 880,000. Between 1910 and 1925 several new residential suburbs (*colonias*) were created, which grew rapidly by the cutting up of adjacent estates (*haciendas*) into building lots; many squat buildings of colonial days in the business districts were replaced by sky-scrapers; new streets were cut; dirty squares were transformed into neat flower-decked plazas and the magnificent National Theatre begun in 1900 was partially completed, 12,000,000 pesos having been expended on it up to 1922. The Legislative Palace, however, was still unfinished in 1925, and was about to be torn down instead of completed. In 1923 the area of the city was about 15 sq. m., divided into eight sections (*cuarteles* or *demarcaciones*), and sub-divided further into about a thousand squares (*manzanas*). There were over 200 m. of tramways, and the tram service, furnished by an English company and managed by English and Canadians, was efficient. At different times the official names of many streets were changed, either to commemorate recent events and heroes, or in the interest of convenience; *e.g.*, all the streets in one section received names of trees and flowers, in another names of foreign cities, so that the character of the name of the street would give a general idea of its location.

Industry and Commerce.—Manufacturing, still relatively unimportant, was represented in 1925 by some 215 establishments, with an annual output valued at 10,000,000 pesos, and employing about 10,000 workers, most of whom were Indians and half-breeds (*mestizos*). The leading products were tiles, cigars and cigarettes, textiles, drugs and chemicals, oils and extracts, shoes and other articles of clothing, various articles of food, beer and other beverages, furniture, iron and steel, mosaics and jewelry. Of greater importance were trade and finance. In Mexico City are the headquarters of most of the business carried on in the country, and it is the principal distributing centre of the republic. Deposits in the banks on Oct. 31 1923 (64,278,894 pesos) were 53% of the total for the country. About 30% of all the imports into the republic are received in the capital. The annual sales of the commercial establishments of all kinds were estimated in 1925 at over 250,000,000 pesos. The textile industry was largely in French hands; hardware, cutlery, chemicals and drugs, in German hands; the oil and mining interests were chiefly English and American; banking, predominantly Canadian; retail trade, predominantly Spanish; but both banking and trade were shared by French, Spanish and Americans, and by 1925 there was a successful National Bank of Mexico. The National Railways of Mexico were returned to private management on Jan. 14 1926, under the so-called Pani-Lamont agreement.

Social Conditions.—An increasing number of automobiles, higher wages, and a decreasing number of bare feet, indicated some advance in prosperity; and a brighter outlook for public health was given by President Calles's firm support of clinics, dispensaries and similar improvements. But the general standard of living of the population was still very low; beggars were exceedingly numerous and very importunate; business was "nervous"; and foreign capital was not available in the amounts needed. The organisation of labour advanced rapidly after the foundation in 1918 of the *Confederacion Regional Obrera Mexicana* (usually referred to as "CROM") by L. N. Merones, an electrician, who became Secretary of Industry and Commerce in the Calles Administration. In the demonstration of May 1 1925, in Mexico City, 93 unions, with 100,000 members, took part.

By 1925 collective bargaining was the rule, and it was claimed that "CROM" had effected an increase in the average weekly wage from 50 centavos to 3 pesos.

Education, etc.—By the constitution of 1917 elementary education was made free, compulsory to the age of 15, and secular, but pending the provision of enough secular schools many of the old schools under religious auspices continued to function. The national university, which had been suspended for half a century, from the time of Maximilian, was re-opened in 1910. A summer school was established in 1922, designed especially to attract foreign students for the study of Spanish. The World War increased the interest of Mexicans in reading, and as a result several new periodicals, of a superior quality, were established in the city, which had the first printing press in the new world and the first regularly issued newspaper. Mexico City was the scene of riots during the revolutionary disturbances of 1910 and 1911. On June 7 1911, the day on which Madero made his triumphant entry into the city, there was a severe earthquake, which cost many lives. In Sept. 1921 the centennial of Mexican independence was celebrated with great pomp.

MEYER, EDUARD (1855–), German historian, was born at Hamburg Jan. 25 1855. He was educated at Bonn and Leipzig, where in 1879 he qualified in ancient history. He afterwards became professor of ancient history at Breslau (1885), Halle (1889) and Berlin (1902). Meyer realised the great importance of folklore, historical monuments and numismatics as aids to the study of ancient history, and the value of his original methods in treating the subject was recognised by the universities of Oxford, St. Andrews and Freiburg from which he received honorary degrees.

Meyer's principal works are: *Geschichte des alten Aegypten* (1887); *Forschungen zur alten Geschichte* (1892–9); *Wirtschaftliche Entwicklung des Altertums* (1895); *Die Entstehung des Judentums* (1896); *Zur Theorie und Methodik der Geschichte* (1902); *Geschichte des Altertums* (3rd. ed. 1909); *Caesars Monarchie und das Principat des Pompeius* (2nd ed. 1919); *Preussen und Athen* (1919); *Ursprung und Anfänge des Christentums* (3 vol. 1921–3).

MEYER, MARIE PAUL HYACINTHE (1840–1917), French philologist (*see* 18.349), died at St. Mandé, near Paris, Sept. 8 1917.

MEYERHOLD, VSEVOLOD EMILIEVICH (1873–), Russian theatrical producer, was born in Moscow and from 1898–1905 was well known as one of the most distinguished actors of the Moscow Art Theatre. He then began to produce plays, adopting a new convention in opposition to the "true-to-life" ideas of Stanislavsky, in which the actor and the stage setting presented a complete harmony. After the Revolution he carried these methods to an extreme, using no curtain and a bare stage with purely formal scenery. He managed the Revolutionary Theatre, Moscow, and also acquired a theatre of his own, and in both produced political propaganda plays. His views are set forth in his book, *The Theatre* (St. Petersburg, 1913).

MEYNELL, ALICE (1849–1922), British poetess. By her marriage in 1877 Alice Thompson became Alice Meynell. She had the fortune to find herself in that mid-Victorian era which still held freshly to its heritage from Keats and Shelley, from Wordsworth and Coleridge. It felt its heart torn by the griefs of the Brontës, stirred by their glories; and almost clung to the hand of Elizabeth Browning. Eagerly awaiting every recurring sign of Tennyson's fertility, it yet respected the long pause of Patmore; and took for its own the volumes of Dante and Christina Rosetti, warm from the press. With these two women of song, Elizabeth and Christina, Alice Meynell's name is now commonly tripled. But it was not they who moulded her thought or her expression. Her aloof independence was proof against all precedents; and of her prose it may be noted that, notwithstanding her love for Lamb and Landor, only the American, James Russell Lowell, is mentioned by her as in any way her master in style. She was her very own spiritual and intellectual self as both woman and writer. That was the secret of the singleness of her personal influence while she lived, and secures an enduring freshness and originality in the work she bequeathed.

Mistress Anne Killigrew had been told by Dryden "thy fathe was transfused into thy blood." That girls alike with boys inherit from fathers as from mothers, was the theme of a vers where Alice Meynell, after the desolations of the European War gave the comforting signal:—

> The crippled world! Come, then,
> Fathers of women with your honour in trust,
> Approve, accept, know them daughters of men,
> Now that your sons are dust.

Her own father, having left Cambridge and unsuccessfull contested two costly elections for Parliament as a free trade became very much a citizen of the world. After his marriag with Christiana Jane Weller, a beautiful and accomplished gi to whom her adoring friend Charles Dickens fitly introduce him, he made his home much in Italy, devoting himself to th liberal learning of the two daughters: Elizabeth, the elde afterwards Lady Butler, famous as a war painter; and Alic who early began to put her rhymed thoughts shyly upon pape Despite the affectionate appreciativeness that ruled her hom (usually an English one) her composition remained mostly he own secret until an American friend, to whom they were confided, encouraged her to show, and then print, them.

The volume of *Preludes* was issued (for the girl wh an association) by Tennyson's then publisher, Mr. Henry King, on the word of his "reader"—later his successor—M C. Kegan Paul, who, not trusting his own judgment all the wa read some of them aloud to George Eliot, receiving her decidi approbation. The critics were mostly silent; and even tho who praised hesitated. But the volume made its own quiet wa Ruskin in all ways first in his soaring praises: "The last verse that perfectly heavenly 'Letter of a Girl to her own Old Age,' th whole of 'San Lorenzo's Mother,' and the end of the 'Sonnet to Daisy,' are the finest things I have yet seen or felt in mode verse." Rossetti, too, spread the news of the young poet advent, reciting "Renouncement" by heart to his friends, an saying that it was "one of the three finest sonnets ever writte by women." Browning, having read a brief quotation buried a halting press appreciation, "conceived the desire to read th rest for myself," and found its beauty "even beyond what th indifference of the reviewer should have prepared me for. The volume brought her many a friend—and more. For th reviewer in *The Pall Mall Gazette*—a paper to which she w later to be a conspicuous contributer—quoted the sonnet "M Heart shall be thy Garden," and found for it a reader whom reached revealingly. A consequent introduction to the sonnete by a common friend was followed by a marriage that fulfilled f him Crashaw's "heaven-on-earth" for 45 years.

On Mrs. Wilfred Meynell, as she then (1877) became, fell long silence as a poet. The muse does not ordinarily leave car on the happily and busily married; the domesticities and th "sweet sense of providing" are not the fashioners of tho "sweetest songs" that breed from "saddest thoughts Eight children were born, one of whom died in infancy: a gri that put into poetry the dread reminder that the giver of life also the giver of death: "and she who slays is she who bears, w bears." A like sensitiveness to life's cruelties put her, for all h reticence, on political platforms, and marched her in multit dinous processions, in favour of the granting of votes to wom and the opening of long closed professional doors. Compassi was the companion of all her walks abroad, for the over-burden man and animal; for the beggar-woman to whom she cried wi her gift, in Portuguese fashion, "Have patience, little saint"; f the underfed in London slums which she at one time sedulous visited; and for the beast in the shambles, in shame for who martyrdom she refused to eat meat until, after persuasion, s sought by more impersonal methods to further laggard reform

Her married life matured her vigilance as a mistress of pros In W. E. Henley of *The Scots Observer* and *The National Observ* she encountered an editor who heartened her by his boisterou welcomes: "That woman's taking her place at the steeri wheel" was one of his recorded acclaims. Later, in *The P Mall Gazette* of Harry Cust's editorship, she was accorded weekly column which left her a large range in the choice of subjects. George Meredith, reading here her “princely journalism,” sought with her an acquaintance that soon became a “dearest friendship.” In a magazine—those were still the days of the magazines—he spoke of her words as having the “living tremor in them,” just as he had before said that Carinthia's had the “throb beneath them.” Of her essays, he wrote: “The surprise coming on us from their combined grace of manner and sanity of thought is like one's dream of what the recognition of a new truth would be. They leave a sense of stilled singing on the mind they fill. The writing is limpid in its depths.”

Coventry Patmore, too, her yet warmer admirer, published, when Tennyson died, his unavailing plea for her succession to the laureateship. Her close friendship for such seniors coincided with that for her contemporaries, and for her juniors, chief among whom was Francis Thompson, who addressed to her his exquisite sequence of poems *Love in Dian's Lap*, of which, Patmore said, Beatrice or Laura might have been proud. Of the homage paid to her, another chosen friend, J. L. Garvin, has well said: “Alice Meynell was in herself a person of her age, ure, as I think, of perpetual remembrance, even if half a dozen of her shining contemporaries had not competed in vain to spoil her with praise. It was what no one could do: recognition only made her humble.” And these contemporary praises otwithstanding, G. K. Chesterton predicts: “She was deserved-y famous; but I will venture to prophesy that her fullest fame is yet to come. The whole modern world must immeasurably nlarge itself before it comes near the measure of her mind.” he died in London on Nov. 27 1922.

Alice Meynell's *Preludes* (1875), long out of print, re-appeared n a volume of *Poems* (1893) including new ones; and these, ogether with yet later verses separately issued as *A Father of Women* (1917) and *Last Poems* (1923), are all assembled in the omplete volume of *Poems* (1923) now in circulation. Of her rose, several small volumes of essays in the eighteen-nineties—*The Rhythm of Life* (1893), *The Colour of Life* (1896) and *The pirit of Place* (1899)—were followed by *Ceres' Runaway* (1909), y *Hearts of Controversy* (1917), by *The Second Person Singular* 1921) and finally by the standard volume of selected *Essays* 1914)—the selection being her own. Other books were *John Ruskin* (1900), *The Children of the Old Masters* (1903), *Mary, e Mother of Jesus* (1912) and *London Impressions* (1898). Two anthologies give her choice among poems—*The Flower of e Mind* (1897) and *The School of Poetry* (1923), the first in-uding Notes and the second Commentaries. She prefaced ditions of *The Sonnets from the Portuguese* and Christina ossetti's *Poems* (1910), as well as a decade of volumes “The Red Letter Library”; she introduced in 1903 a volume of eproductions of Sargent's Portraits; and she made for English aders a Selection from the Poems of J. B. Tabb (1906).

Bibliography.—Reference may also be made to the critical hapters concerning her in Alfred Noyes' *Some Aspects of Modern oetry* (1924); in John Drinkwater's *The Muse in Council* (1925), nd in Katherine Brégy's *The Poets' Chantry* (1912); as well as to ch notable articles appearing at the time of her death as J. L. arvin's in *The Observer*, J. C. Squire's in *The London Mercury* and . K. Chesterton's in *The Dublin Review;* articles that quickened e desire for the authorised biography now (1926) in preparation.

(W. Me.)

MIAMI, Fla., U.S.A. (*see* 18.354), in the centre of the 200-m. rip of the “East Coast” which is dotted with winter resorts, as a focus of the rush to Florida which began about 1922. he population in 1910 was 4,571; in 1920, 29,571; in 1925, cording to the state census, it was 69,754. In Sept., after nexations of territory, it was estimated at 100,000 within e corporate limits, and at 150,000 within six miles of the urt-house. Between 1914 and 1924 bank deposits increased er 3,000%; post-office receipts and property valuation each er 600%; the value of buildings for which permits were issued, er 2,500%, and the total of such permits for 1924 was doubled the first eight months of 1925.

At the opening of the winter of 1925–6 all kinds of shelter ere at a premium, and tent colonies sprang up until they presented a serious sanitary problem. For the moment, speculation in land was the leading occupation (a third of the members of the Chamber of Commerce were dealers in real estate), but there were solid foundations for future prosperity. Though later in 1926, the value of land fell to some extent. The Federal Govt. had begun work on harbour improvements. Draining of the Everglades by the state was opening to agricultural settlers thousands of acres of rich swamp land, forty-five varied industrial plants were already in existence, and a sugar-mill and refinery were in operation 16 m. out on the Miami canal.

Miami Beach, across Biscayne Bay, one of the most luxurious winter playgrounds of the country, was a mangrove swamp in 1910. Coral Gables, a separately incorporated residential suburb adjoining Miami on the south, was developed in Spanish and Moorish architecture with six miles of Venetian waterways. This was created in a few years by the magic of immense investments of capital, modern engineering and far-sighted planning including a tract for the University of Miami, chartered April 5 1925 which had in view an endowment of $15,000,000.

MICA (*see* 18.355).—The three main contributors to the world's supply in order of importance are the United States, India and Canada. After the outbreak of the War the stoppage of the mica imports to Germany had a depressing effect on the mica industry; but, on the other hand, the large amount of mica required for munition purposes, gas-masks, etc., caused both the Allies and the United States to import increasing quantities of sheet mica from Argentina and Brazil. In the United States the mica mined is mainly muscovite, occurring as irregular masses, sheets and lenses in pegmatite veins traversing metamorphic rocks. The principal producing states are North Carolina and New Hampshire, but Virginia, South Dakota, Georgia, Alabama, Idaho and Colorado also produce considerable amounts.

The chief mining centres in India are the great Bihar mica belt, about 60 m. by 12 m., traversing the Menghyr, Hazaribagh and Gaya districts in the province of Bihar and Orissa; and the Nellore district in the Madras Presidency. Less important areas occur in Ajmer Merwara in Rajputana. The Canadian mica is almost entirely phlogopite. The deposits occur chiefly in Quebec to the north of Hull, and in the townships of North Burgess and Loughborough in Ontario.

The World's production figures in long tons for 1913, 1918 and 1923 were as follows:—

	1913	1918	1923
India (exports)	3,124	2,998	3,948
Canada	986	667	2,331
Other U.K. countries	118	51	127
United States (chiefly sales)	5,511	2,780	8,112
Madagascar	6	4	162
Argentina (exports)	6	169	100
Other foreign countries	10	190[1]	587[2]

[1] Including Brazil 112 tons.

[2] Including Japan 424 long tons.

(N. M. Pe.)

MICHELSEN, PETER CHRISTIAN HERSLEB KJERSCHOW (1857–1925), Norwegian statesman, was born at Bergen March 15 1857, the son of a prominent merchant and shipowner. After completing a university education in 1879, Michelsen settled in Bergen as a lawyer and at the same time entered the shipping business in which he achieved considerable success. Known as an administrator, he entered the city council of Bergen and later the Storting where he took his seat in 1891 and quickly became one of the most prominent members. In 1894 he withdrew from politics, returned to Bergen, resumed his activity as a shipowner and re-entered the city council of which he became the chairman. The general elections in 1903 by which he returned to the Storting as a member for the country district outside Bergen initiated the crowning period in Michelsen's public career. Appointed Prime Minister in the spring of 1905 Michelsen played a leading part in the events which resulted in the dissolution of the union with Sweden and the establishment of the new kingdom of Norway. In 1907 he definitely retired from politics and died near Bergen June 29 1925.

MICHELSON, ALBERT ABRAHAM (1852–   ), American physicist, was born in Strelno, Germany, Dec. 19 1852. His parents moved to San Francisco, Cal., where he studied in the public schools. He graduated from the U.S. Naval Academy in 1873, and was instructor in physics and chemistry there during 1875–9. He was then for a short time in the *Nautical Almanac* office. From 1880 to 1882 he studied in Berlin, Heidelberg and Paris. He resigned from the navy in 1881. In 1883 he was appointed professor of physics at the Case school of applied science, Cleveland, O., and six years later accepted a similar position at Clark University. In 1892 he was appointed professor and head of the department of physics at the University of Chicago. He early directed his researches to the velocity of light, and while in Cleveland invented his interferometer (*see* 14.693), which enabled him to measure distances by means of the length of light-waves. His researches enabled him to revise and improve upon the achievements of Fizeau in respect of the velocity of light. He perfected the methods for experimenting, and determined the rate at which light travels, with an error not exceeding $\frac{1}{10}$ of 1% of the quantity measured. Through one of his experiments it was demonstrated that the speed of light is the absolute superior limit of the rate at which matter can move, because the mass of a body depends upon its velocity —mass diminishing as velocity increases—and a body would vanish completely if it exceeded the velocity of light.

Michelson measured a metre in terms of the wave-length of cadmium light for the Paris Bureau Internationale des Poids et Mésures. The consequence is that the metre bar, hitherto carefully safeguarded in Paris, can easily be replaced, since its length is known in terms of an absolute unit. In 1892 he was a member of the Bureau Internationale des Poids et Mésures and in 1897 of the International Committee of Weights and Measures. He was made president of the American Physical Society in 1901 and of the American Society for the Advancement of Science in 1910. He received medals and prizes from many learned societies, and in 1907 was awarded the Nobel Prize for physics. During the World War he rejoined the naval service and devoted his entire time to new devices for naval use. His range-finder was adopted as part of the U.S. Navy equipment. In 1920 he was able to demonstrate by means of light-interference that the diameter of Alpha Orionis was 260,000,000 miles. This was the first computation ever made of the size of a star. He was the author of *Velocity of Light* (1902); *Light Waves and Their Uses* (1903), and numerous papers contributed to scientific journals. In 1921 he was awarded the gold medal of the Society of Arts, London. (For the "Michelson-Morley experiment" in interference of light, with its bearing on the Einstein theory, *see* RELATIVITY.)

MICHIGAN (*see* 18.371).—The population of Michigan in 1920 was 3,668,412, an increase of 30·5% over 1910. The estimated population as of July 1 1926 was 4,395,651. Of the total population in 1920, 1,670,447 were of native parentage; 1,204,545 of foreign or mixed parentage; 726,635 were foreign-born and 60,082 were negroes. The following cities in 1920 had 50,000 inhabitants or over: Detroit (993,678); Flint (91,599); Grand Rapids (137,634); Lansing (57,327); and Saginaw (61,903). A special census of Detroit on May 31 1925 gave its population as 1,242,044 on that date.

Education.—In 1920 there were in the state 1,048,390 persons of school age, of whom 710,341 (67·8%) were attending school. The illiteracy rate was 3% in 1920 as against 3·3% in 1910. In many of the public schools vocational courses were added in recent years. At the institutions of higher education, attendance greatly increased. Some of the colleges with church connections shared in this growth; but the chief enlargement was at the University of Michigan (*see* MICHIGAN, UNIVERSITY OF) and the Michigan Agricultural College. To add to the facilities for higher education, "junior colleges" with curricula covering two years of college work, were established in Detroit, Grand Rapids, Muskegon, Pontiac and Highland Park, in connection with their secondary school systems.

Agriculture.—In 1925 there were 192,334 farms in Michigan, a decrease of 14,626 as compared with 1910. During the 15 years all farm land decreased from 18,940,614 ac. to 18,036,700. During the same period the average acreage per farm increased from 91·5 to 93·8. The average value of land and buildings per ac. in 1925 was $71.41. In 1925 a total of 9,671,670 ac. was under cultivation, on which crops valued at $268,674,000 were raised. The farming area of Michigan continues to be concentrated mainly in the southern part of the lower peninsula of the state. In the upper peninsula, farms comprise less than 10% of the land area. The area nominally in woodland, including farm woodlots as well as forests and cut-over lands, comprises nearly two-thirds of the state; but of this area not more than about 5,000,000 ac., nine-tenths of which lies in the upper peninsula, now bears timber worth cutting. Most of the rest has come to be stump lands, on which the recurrence of fires prevents any spontaneous reforestation. The barrenness of the sandy soil and the shortness of the growing season have hindered the reduction of land to cultivation, and some 10,000,000 ac. (more than one-fourth o the total surface of the state) are thus a deforested desert Several thousand acres of it revert to the state each year i default of taxes. These reverted tracts, comprising 566,850 ac in 1918, are administered by the Public Domain Commission (created in 1915) with a view to the sale of such as can be used a agricultural homesteads and to the setting aside of the rest a forest reserves. These forest reserves (648,000 ac. in 1923) ar under state forest management for the prevention of fires and fo systematic reforestation.

Minerals.—In mineral production no new resources of importance were developed during the period 1910–25. Th mining of iron-ore continued vigorously, that produced in 192 amounting to 14,069,938 tons. The production of copper wa pushed to the fullest capacity during the World War; but th severe decline of the market after the Armistice caused a sharp reduction of output. The amount of copper produced in 1923 wa 138,304,680 pounds.

Manufactures.—The manufactured products in 1923 wer valued at $3,870,434,000, as compared with $685,109,000 i 1909, an increase of nearly 465%. This advance was mainly du to the extraordinary growth of the automobile industry and it concentration in the state. The value of automobiles manufactured increased from $7,996,534 in 1904 to $96,651,451 in 1909 and to $1,551,990,000 in 1923. In more recent years this industry has continued its rapid expansion. It is estimated tha more than two-thirds of the automobiles manufactured in th United States are made in Michigan. The number of wage-earners engaged in the making of automobiles and their parts i 1914 was 67,538, constituting 24·9% of the total number o wage-earners in the state; these were increased to 149,296 i 1923, their proportion to the whole being 29·6%. Foundries an machine shops with an average number of 34,080 wage-earner in 1923 produced products to the value of $165,736,521. Furniture ranked next, with 20,665 wage-earners and products value at $93,039,416. Other industries, including logging and sawmi operations, engines and water-wheels, paper and wood pul substantially increased. Michigan led all other states in output of chemicals, drugs, engines, threshing-machines, furniture and efrigerators.

Finance.—In 1923 the assessed value of property in Michigan was $5,929,615,241, on which the state levied $25,880,702 in axes ($6.58 *per capita*). In the same year the funded and loating debt of the state amounted to $70,613,011, with a net lebt of $65,655,186, or $16.69 *per capita.* Appropriations by the Legislature, $5,929,306 in 1909, advanced steadily to $9,610,553 n 1915, and then much more rapidly, standing at $28,302,639 or 1926–7. The volume of the general property tax, which omprised nearly all the state's revenue, lagged behind the ppropriations at the close of the decade 1910–20, and the rospect of a treasury deficit in 1921 caused the passage of a law or a tax on corporation franchises as an emergency recourse. n 1921 accounting and purchasing were centralised under the tate Administrative Board. The result of these measures was hat a deficit of approximately $6,000,000 in 1921 was replaced y a surplus on July 1 1925 of $2,292,411.

Legislation and Administration.—Amendments added to the evised constitution of 1908 provided for popular initiative and eferendum on constitutional amendments and in legislation 1913); for the recall of elected officials (1915); for prohibition 1916); for woman suffrage (adopted in 1917 after having been uccessively rejected in 1912 and 1913), and for the issue of state onds to the amount of $50,000,000 for the improvement of ighways (1917). The provisions for initiative, referendum nd recall have as yet found little utilisation, but the issue of ighway bonds facilitated a marked improvement in roads. n increase of the licence charges on automobiles has also in- eased the road funds, the application of which is largely deter- ined by an Act of the Legislature (1915) establishing a system of ate trunk roads. A further increase of road funds resulted from acing in 1924 a tax of two cents per gallon on gasolene. This elded a substantial sum.

Among other noteworthy enactments by the Legislature are the idicature Act of 1915, consolidating and revising the laws of vil practice and procedure; the "blue-sky" law of 1913 and e creation of the Michigan Securities Commission in 1915 to gulate the sale of securities; the provision for juvenile courts 911); the creation of a Board of Mediation and Conciliation to al with labour disputes (1915); a Dept. of State Police (1919); budget commission (1919); and a state Administrative Board, nsisting of all the elective state officials (1921). This board was trusted with a general supervisory control over the functions d activities of the administrative departments, each of which, reorganised and consolidated, continued to operate separately th an appointive official at its head. The preparation of the dget and matters of state expenditure were placed directly der the control of the board. Michigan ratified the Eighteenth rohibition) Federal Amendment Jan. 2 1919.

Political History.—Since 1910 there generally have been ge Republican majorities in state and national elections, with- t appreciable representation of any other parties in the state gislature. In the presidential election of 1912, however, ichigan gave its electoral vote to the Progressive ticket, and in 12 and 1914 it elected a Democrat as governor and in 1923 cted the same man to the U.S. Senate. The governors of ichigan, 1911–25, were: Chase S. Osborn (Rep.), 1911–3; oodbridge N. Ferris (Dem.) 1913–7; Albert E. Sleeper (Rep.), 17–21; Alexander J. Groesbeck (Rep.), 1921–5 and 1925– . a conspicuous contest in 1918 Truman H. Newberry (Rep.), s elected to the U.S. Senate by a narrow majority over nry Ford (Dem.). Charges of excessive expenditures in this npaign were brought against Senator Newberry and numerous ociates, and they were convicted in the U.S. District Court 20) and were sentenced to two years' imprisonment. The S. Supreme Court set aside the conviction May 2 1921; on . 12 1922 the U.S. Senate decided by a vote of 46 to 41 that wberry was entitled to his seat. In the ensuing senatorial ction, however, he was decisively defeated at the polls, whereon he resigned the seat. (U. B. P.)

MICHIGAN, UNIVERSITY OF (*see* 18.378), has continued the promise of its earlier period as the first conspicuously successful state university. The faculty increased from 350 in 1907–8 to 797 in 1925–6, while the student enrolment grew from 5,013 to 12,312 (6,010 in the college of literature, science and the arts; 1,716 in the colleges of engineering and architecture; 536 in the medical school; 541 in the law school; 85 in the college of pharmacy; 358 in the college of dental surgery; 483 in the school of education; 23 in the school of business administration; 758 in the graduate school; 190 in the training school for nurses; and 3,147 in the summer session). On July 1 1925 there were 36,500 living graduates.

Among the buildings erected between 1910 and 1925 were Hill auditorium (1913) bequeathed to the university by Regent Arthur Hill, of Saginaw, seating 5,000 persons; the Natural Science building (1916); the university library (1919), containing approximately 400,000 vols.; the Michigan Union (1919), a student club-house, costing $1,250,000, the gift of students and alumni; the engineering laboratories (1923); the Wm. L. Clements Library of American History (1923), containing one of the three largest collections of Americana in the United States, the gift of Regent Wm. L. Clements, of Bay City; the Yost Field House (1923); James Burrill Angell Hall (1924); the Lawyers club and dormitories (1924), the gift of W. W. Cook, of New York; the physics building (1924); the university high school (1924); the medical building (1925); the university hospital (1925), accommodating 700 patients. Four dormitories for women students were also erected during this period as well as a home for nurses, the gift of Senator James Couzens, of Detroit. A new building for the College of Architecture is in course of construction and a new museum will be built in 1927. A stadium, seating 70,000, will also be completed in 1927.

The income of the university in 1925 was $12,465,160. Of this amount $3,000,000 was derived from the state from the ⅝ mill tax; $2,683,855 was appropriated by the State of Michigan for buildings, and $1,240,889 was received from student fees. Over 12,000 graduates and students of the university were enlisted in the U.S. Forces during the World War. Of these, 237 lost their lives.

Upon his resignation in 1909, President James Burrill Angell was succeeded by Harry Burns Hutchins, dean of the Law School. President Hutchins resigned in 1920 and was succeeded by Marion Leroy Burton, who had been president of Smith College (1910–7) and of the University of Minnesota (1917–20). Upon his death in 1925, Clarence Cook Little, formely president of the University of Maine (1922–5) was inaugurated sixth president of the university.

MICROBE: *see* FILTER-PASSING MICROBES.

MICROPHONE.—The term microphone, originally used by Hughes to describe a loose contact device extremely sensitive to vibration, has been generalised to mean any piece of apparatus for converting rapid vibrational energy into electrical energy with similar vibrational characteristics. A number of such devices are now known; some are of scientific interest only, others are used very extensively in industry.

Microphones Proper.—A loose contact between any two conductors is microphonic—that is to say, when subjected to vibration there is no sharp definition between completely open circuit and completely closed circuit. In between these two states there is a condition where varying pressure alters the resistance, and if one or both of the substances making contact are subject to vibratory pressure, the vibration is reproduced as a varying current. The characteristic between pressure and current is only linear over small limits.

The action at the point of contact is not exactly known. When the current passing through the contact while in the microphonic condition is examined it is found not to be absolutely constant, and this lack of constancy makes itself evident as a hiss in a telephone receiver. The discharge through a vacuum valve has a very similar sound when amplified.

The change of resistance with pressure varies greatly with materials used. Carbon in one form or another is universally recognised as the best material, in that the transitory stage between open and closed circuit is more marked than with other materials. This does not mean, however, that it gives the greatest change of resistance for a given change of pressure. A contact between gold electrodes by delicate adjustment can be put in a sensitive condition, and in the adjustment gives greater changes than carbon for the same change of pressure. A considerable amplification can be obtained with microphonic contacts, the output vibratory electrical energy being many times that of the input mechanical energy.

FIG. 1.—Western Electric carbon Microphone.

To Edison, Berliner, Hughes and many others we owe the introduction of the contact microphone and its development as a practical device, and microphones to translate noises and music have been produced in many forms. The inventive drift has been towards multiple contacts, and practically all contact microphones are now formed of prepared anthracite granules, the sound pressure being applied in various ways, usually by means of a diaphragm. In later years a more accurate study of the response of microphones to sound pressure has been made, and two modern forms in which the response is practically independent of frequency have been made.

In the first form, the Western Electric carbon microphone (fig. 1), a diaphragm of duraluminium is stretched to a natural period well above the frequency it is required to reproduce. A type of air damping is applied to the diaphragm, and it is allowed to rest on carbon granules. The resulting currents are practically independent of frequency. In a second form, known as the Reisz microphone (fig. 2), a diaphragm is practically dispensed with, and a layer of carbon granules is laid on a heavy non-conducting block such as marble, being held in position by some materia such as silk or thin rubber. The current response is obtaine at right angles to the direction of application of pressure.

The carbon granule-air system of a thickness of about 2 mm forms a system of a very high natural period in depth, als damped by the natural friction of the carbon. The resultin response is similar to that of the stretched diaphragm type d scribed in the last paragraph. Lowering the period of the dia phragm or thickening up the layer of carbon granules in thes two types has similar results. These high quality microphone are not sensitive and have to be used with a valve amplifie In commercial telephony this amplification is not usually pe missible, at least to such an extent, so that it is usual greatl to increase the sensitiveness by forgoing some of the accurac of response.

Fortunately the human voice can be considerably distorte without lack of intelligibility, and by giving the diaphragm the microphone a natural period in the middle of the importa frequency ranges (about 800 cycles) amplifiers can be dispense with owing to the increased response; music, however, cannot b reproduced with anything like fidelity. These microphones a also used well outside their range of linear response. Granu microphones all suffer to some extent from "packing"—that is, tendency for the carbon to set itself in a hard contact conditio where change of resistance with pressure is least, and much tim has been spent in an attempt to overcome this difficulty. Th commercial solid back microphone is one of the best forms, bu occasional shaking is still necessary.

Other Response Devices.—The best known of non-contact d vices is the E.S. microphone, developed into an instrument precision by the Western Electric Co. Ltd. (fig. 3). Here th same principle is used as in the carbon microphone. A hig natural period diaphragm, air damped, forms one plate of condenser, the other being a solid insulated metal piece spac a few mils from the diaphragm. The chief use of this instrume is for measurement and for broadcasting. The amplificatio required is large. Various magnetic microphones have be

nstructed; in fact, the first Bell microphone was practically e present receiver. The response with frequency is, however, complex curve, although it is more linear with amplitude than contact device. Moving coil devices have been produced by kes, Siemens-Halske, etc., the later forms of instrument being nstructed so that the moving coil is the diaphragm.

In the Sykes microphone (fig. 4) an annular ring of aluminium l or wire is suspended in a magnetic field, and the response sufficiently large to enable the method to be used for broadsting. The law of response with frequency, although not arly so correct as the electrostatic instrument, can largely corrected for in the amplifier.

Thermal Devices.—Hot metal wires have been used for microone purposes. The response is, however, small except for very v frequencies, which property has been used by Tucker for n-ranging usually in connection with a resonance chamber.

Gas Discharge Devices.—Dr. Thomas, of the Westinghouse ectric Co., and others have investigated the use of point disarges, but these devices have not come into general use. A me carrying a current is sensitive to sound, but the effect is small for practical purposes. The piezo electric effect has o been used, but not with much success, except for very high quency work. See H. M. Dowsett, *Wireless Telephony l Broadcasting* (1923). (H. J. R.)

MICROSCOPY (*see* 18.392).—The modern microscope is entially a working tool used in every form of scientific and ustrial research. Specialised applications have led to the lution of instruments designed for robust usage as factory pliances, and at the other end of the scale we have the new e of biological research microscope initiated by Mr. J. E. rnard, F.R.S., F.R.M.S., and manufactured by Beck. In h types there is a marked tendency to forsake the older table form of stand used in normal laboratory practice and ke use of a massive optical bench or lathe bed type of stand. s gives enormously increased rigidity, and freedom from ration, enables the accessory lighting and condenser systems to permanently adapted to the optical axis of the instrument, permits quick change from visual observation to photograph ording without disturbance of adjustments.

Denne Microscope.—In the microscope designed by Mr. M. T. nne, F.R.M.S., for photomicrography, the whole system of minant, condenser, filter, substage condenser, stage and ective are all mounted on a triangular optical bench. This in n is carried on a carriageway or lathe bed on which it is free nove. No conventional coarse or fine adjustment is fitted to microscope, and the place of the body is taken by a camera. coarse and fine focusing are operated by crank handles ring screw rods in the bed. These control handles are situated he focusing screen end of the camera. For visual observation whole optical system is brought up to the camera, which is scoped, the focusing screen is swung to one side and an eyee is inserted in its place. The complete apparatus is mounted a wheeled pedestal carriage, and the operator manipulates whole from a chair at the focusing screen end of the bench.

ptical Problems.—In biology research has been directed to nding the limits of microscopic resolution by the use of ochromatic light of short wave-length. The limit of resolu—that is to say, the power to see a body composed of two as two separate dots in ordinary white light—is reached standard apparatus, when the distance separating the two is reduced to half a wave-length of ordinary light (say 0·2 Bodies far smaller than this can still be perceived as vague s of light, but the eye cannot distinguish form or structure. re is in theory no limit to the smallness of a body which can nade visible, provided that enough light falls upon it, but image we see of it is simply a series of diffraction disks, and give us no further information than that something is there. duction in the length of the wave-length of light employed be looked on as increasing the separation between the two ts in a body. Thus an object easily visible, but just too small e resolved, by ordinary light with a proportion of the long rays in it, may be resolved and seen by monochromatic light from the blue end of the spectrum. As we pass toward the violet end we find that the eye is not sensitive to the violet, and that both distinct vision and accurate focusing become increasingly difficult. This band of light is, however, suitable for photography, and, although visual observation may be imperfect, photographs taken with this light reveal unseen detail and structure (*see* PHOTOGRAPHY).

In 1904 Dr. Köhler of Jena experimented with the use of ultraviolet light. This band of light is of very short wave-length—275μμ—and possesses great resolution, but is invisible. He employed an optical system of quartz lenses, as glass stops these rays, and projected the image on a fluorescent screen where it could be examined with a glass eye lens and focused for photography.

Ultra-violet Ray Illumination.—In Great Britain the use of ultra-violet ray illumination has been applied by Mr. J. E. Barnard, F.R.S., and the technique simplified and developed. In the Barnard instrument quartz lenses, slide and coverglass are used, but in place of the older method of focusing on a fluorescent screen the object is first focused visually by means of a special form of dark ground illumination.

Dark ground illumination is entirely different from the normal illumination by transmitted light, in that the object is illuminated solely by rays of light so oblique that they cannot enter the objective of the microscope. The only light which enters is that reflected or scattered by the object itself. Objects viewed in this manner appear self-luminous against a dark background, and extremely tenuous and transparent material which would display no structure and be almost invisible when examined by transmitted light reveals material detail. Mr. Barnard's method was to focus the object first by means of visual examination against the dark ground. This focusing was necessarily crude, as the smallness of the objects only allowed them to be seen as disks of diffusion, not as distinct objects. It then becomes necessary to adjust the focus for photography with transmitted ultra-violet light. To effect this, the fine adjustment screw of the microscope is fitted with a disk head graduated in wave-lengths. Visual focus having been determined in light of known wave-length, rotation of the graduated head to the degree indicated for light of any other wave-length automatically adjusts the focus. The eyepiece is replaced by a camera body and dark slide. The dark ground illuminator is so contrived that it can be instantaneously changed over to a direct light condenser without disturbance of adjustment, and the lighting arrangement is arranged so that a beam of ultra-violet light of 275μμ from a cadmium arc can be directed into the optical axis. The photograph taken of the objects indistinctly discerned shows them in actual form and with considerable detail.

Special Difficulties.—Many difficulties have had to be met in this new technique. Bacteria are killed by exposure to ultraviolet rays, and search has had to be made for bands in the invisible spectrum whose effect is not immediately lethal. The most important published results to date are those connected with filter-passing organisms associated with cancer research (*q.v.*) by Dr. Gye, but the normal application of the apparatus may find fuller scope in the exploration of the structure of known bacteria of larger size. These are usually only visible under dark ground illumination when alive, and in order to render them visible for examination by transmitted light they are stained with aniline dyes. Staining kills the bacteria and alters structure. With ultra-violet light methods it becomes possible to examine the structure of living bacteria, for the different elements composing the cell present different degrees of absorption or transparency to the rays, and are as well differentiated on the negative as stained preparations (*see* BACTERIOLOGY).

The standardised model of the Barnard microscope will be approved and available as a commercial product for scientific workers. In the meantime experimental work is being done on the utilisation of even shorter wave-lengths in the Schumann region of the far ultra-violet. These rays have little penetrative capacity through air, and apparatus is being constructed to work in vacuum which may lead to a still further advance in our means of photographically investigating minute structure beyond our present human range of vision with the best of microscopes.

Use in Applied Science.—The extension of microscopic resolution by the use of light of short wave-length and quartz optical systems has not yet found application in other than biological research. The tendency is, however, to apply high power examination to crystal structure in metallurgy, and branches of research dealing with opaque material which cannot be examined by transmitted light. Modern design has endeavoured to simplify the problems of the illumination of metallurgical and similar specimens. Devices embodying a parabolic mirror surrounding and integral with the ordinary objective have proved to be too cumbersome and heavy to be satisfactory in practice. In the same way the claims for the nominal "super microscope" devices, which consist of a primary low power microscope coupled to a second microscope of lower power whose function is to magnify the image given by the first system, have not received general endorsement. The results have been in accordance with optical theory, and have not yielded any increase of resolution. For the observation of incandescent bodies or micrometric measurements at a distance, an achromatic lens of short focus carried in a tube fitting the substage is useful. It acts as a short range telescope, producing an image in its focal plane which can be examined by a low power objective of the microscope, with satisfactory magnification, and gives a convenient depth of focus useful in the examination of large objects with uneven surfaces.

Use in Metallurgy.—For routine metallurgical work the inverted microscope with duplicate tubes for simultaneous visual and photographic work has largely superseded the older types of instrument. With the inverted microscope the specimen of metal is viewed from beneath. Light from an arc or "Pointolite" lamp is led into a vertical illuminating system beneath the objective and projected on to the specimen. The principle is the same as in simpler metallurgical microscopes, but in the newer type a very wide variation of illumination method is possible. Plain glass reflectors, silvered circles, half circles or strips or even parabolic mirrors can be used in the vertical illumination system of the inverted type of microscope. In addition to this convenient command of illumination, the focusing system has only to carry the weight of the objective and is relieved of the conventional tube. This enables a very fine and precise adjustment of focus to be simply obtained. The change from visual observation to the camera is attained by pushing an intercepting prism out of the optical axis of the apparatus.

Use in Engineering Work.—As the microscope is increasingly used as a purely workshop tool in mechanical engineering practice, there has been a demand for simple robust devices consisting of a low power objective and an eyepiece with a simple scale or graticule in its focal plane. These tools have a linear magnification of ×16 or ×20, and enable the tool maker and mechanic to achieve a very high standard of precision. In general, no focusing device is provided for the simpler types, the instrument simply being placed on the flat surface under examination. More complex devices are available for the study of fine screw threads, and the more elaborate types of workshop microscope are fitted with an electrical vertical illuminating device in permanent adjustment. In general these simplified tools may be looked on as precision measuring devices rather than instruments for microscopic investigation. The use of the high power microscope for the examination of the microstructure of metal has led to a realisation of the basic fact that the mechanical properties of metals and alloys, such factors as hardness, ductility and tenacity, are inter-related with the microstructure. The microscope alone does not afford an explanation of many of these properties, but when microscopical examination is used in conjunction with equally accurate chemical and thermal analyses, the behaviour of individual constituents can be determined and information of the greatest possible value has already been gained.

Other Industries.—In the textile industries the microscope is used from the first to the last stages. It is the weapon of the economic botanist studying the insect and fungus pests which attack the plants furnishing the raw material, and it is used by the dye chemist studying the ultimate detail of the decoration of t finished product. Each industry evolves its own particul detail of technique, but, in general, the normal research does n involve special apparatus and the conventional microscope co mon to all laboratories serves.

Colloid Chemistry.—The research chemist who deals wi colloids, a subject of increasing importance, has to meet probler concerning suspensions of ultra-microscopic particles. For th the apparatus known as the ultra-microscope is used. In th the power of resolution is neglected and the design is to ma visible rather than to define extremely small ultra-microscop particles. The ultra-microscope is essentially a dark-grou illuminating device, employing an intense illumination syste and using magnifications up to ×1500, and the particles are se as diffusion disks. The simplest form is the Siedentopf "Ca dioid" condenser, which is a paraboloid dark ground illuminat applicable to the ordinary microscope substage.

It is, however, used with special quartz slides, as the intensi of the illumination is so high that glass fluoresces and destro the darkness of the background. In order to estimate the quan ty of particles present in a given volume, the quartz slides us with the cardioid condenser are similar to those used in t haemacytometer. A central table surrounded by a groove ground down to a lower level than the surface of the slide, that a known depth of liquid can be enclosed between cover a slide.

A more precise form of ultra-microscope is the Siedentop Zgismondy slit ultra-microscope, in which a beam of light fro an arc is passed through a condenser and focused on an adjustab slit, similar to that used in a spectrometer. The image of the s is reduced to a quarter size by a second condenser, and focus by an independent microscope objective on a small quartz wi dowed tank containing the liquid under examination. As t length and breadth of the slit can be adjusted and the reducti is known, the volume of the illuminated portion of the liqu under observation can be accurately estimated. The area of t illuminated zone observed is controlled by an eyepiece stop, a it is possible to count the number of particles in a known volu of solution. If a larger known volume of the solution is evaporat and the residue weighed, the total mass of particles can calculated and the mass and, if its density is known, the volu of a single particle is estimated.

The limitations of the ultra-microscope are those of the fractive index of the objects observed. Cellulose, starch a other low refracting bodies can only be observed in relative large particles, but metallic colloidal solutions of high refracti index have given extremely favourable results. Colloidal g particles as small as $1{\cdot}7 \times 10^{-7}$ cm. in diameter can be observ as separate entities.

Modern Apparatus.—These more recent types of resear apparatus, the ultra-violet ray microscope, the inverted met lurgical microscope, and the ultra-microscope, are specialis instruments and will not supersede the standard instrume for ordinary work. The design of the latter may be looked on stabilised, and no great advance has been made. The modific tions introduced in practice are those of detail and convenie rather than material alteration of type. The increasing use microphotography as a recording device has made the narro bodied microscope of Continental design relatively obsole The best modern instruments have body tubes of two inc or more in diameter.

Improvements in binocular microscopes have now reache point where binocular eyepiecing can be used with the high powers and oil immersion objectives. The advantages of t binocular system are a stereoscopic effect and a great relief fro ocular fatigue. In the past, the old-fashioned Wenham pri type binocular was the only satisfactory system, and it was o applicable to very low powers and to the old "long tube" sta Attempts to adapt a binocular prism system to the higher pow were not successful, and various shortcomings such as unequ light distribution in the tubes have hitherto proved insuperab The new eyepiece systems have now been adopted by the leadi ritish and American makers and have proved satisfactory in ractice. Monocular and binocular bodies are detachable and terchangeable on the same stands. Eyepiece focusing for disarity of vision between the eyes and interocular width adjustent are provided for.

As a result of research, and in a measure as the outcome of artime needs, Great Britain is producing the highest grades of ptical glasses according to tests carried out by the National hysical Laboratory. This mastery of material (*see* OPTICAL LASS) has reacted on the microscope manufacturers, and British icroscope objectives are being adopted for the most critical search work.

MIDDLESBROUGH, England (*see* 18.412), with an area of 4,159 res, had a population of 131,070 in 1921. The town was given eparate court of quarter sessions in 1910. The efforts of the rporation to deal with the housing shortage have been notable: addition to 1,283 houses contracted for, of which 877 were ished in 1925, two large buildings were converted into flats, and umber of hutments were erected at Marske-by-the-Sea for the commodation of Middlesbrough families. The corporation rchased the omnibus and tramways undertakings in 1921. rton, an estate of 136 acres, was presented for use as a public k in 1924. The sum of £40,000 was given by Mr. J. Constane for a technical college in 1916, but, owing to the War and rise in costs, the work could not be proceeded with until a ther £40,000 was given by his widow and family. The Constane Technical College was under construction in 1925. Docks for all vessels and a landing stage were being built in 1926, and area prepared for extensions of the docks.

IIDLETON, WILLIAM ST. JOHN FREMANTLE BRODRICK, EARL OF (1856–), British politician (*see* 18.419), did not nain long out of Parliament after his defeat in the general ction of 1906, as in the following year his father died, and he ered the House of Lords as 9th Viscount. He took a considere share in the work of that House, and played an active part ind the scenes in Conservative politics, without returning to ce. He had meanwhile become especially prominent as leader he southern Unionists of Ireland, in virtue of his position as a downer in County Cork. In the Irish Convention of 1917–8 and a band of Southern Unionists separated themselves from Ulster standpoint and expressed a readiness to concede a tary Home Rule Government for Ireland, subject to provisions safeguarding the minority of loyalists. At the beginning of o he was created an earl.

IIGRATION (*see* 18.427).—The general characteristics of the vement of population between 1909 and 1924 were:—

ince the opening of the 20th century most states had begun to t a positive control in questions of migration; its enormous ease made state regulation of overseas migration unavoidable.

Vith the improvement of communications, many migrants have ntention of settling permanently and becoming naturalised over-. The annual figures of repatriation from the United States e frequently amounted to more than half of those of immigration. s is no longer due solely to the difference between conditions of g in the countries of emigration and immigration; rather, and ncreasing degree, to the more or less conscious efforts of the ntries of emigration to preserve their nationals' love of their es, or those of the countries of immigration to assimilate the elements. The countries of emigration encourage, as far as pos-, temporary migration, to which, however, even before the War countries of immigration raised economic and social objections. uring and after the War, in addition, national and political ts of view began to influence migration policy decisively. In the ntries of immigration, especially the United States, legislation rning selection became more stringent, and later a numerical was imposed on immigrants. The European states were no er able to divert their surplus population overseas so copiously efore; even in the case of racially kindred nations, or the British governing Dominions. These Dominions too, under the pressure conomic depression, seek to retard immigration.

Migration has diminished, since the supply of emigrants does not tally with the demand in respect of nature and quality (race, sex and age).

The one-sided interference with immigration by the opposing groups of states results in social conflicts within those states and friction between their respective governments.

A peculiar characteristic of recent years is the increasing importance of continental migration within Europe. The social problems arising in the countries concerned are regulated in many cases by inter-state treaties (Migration Treaties, properly so-called, going beyond the International Labour Agreements) and if possible international agreement. This is the only way to avert dangers which threaten peace, and to further the social policy of the world in positive fashion.

The immediate problem is that of successfully settling Europe's surplus urban industrial population in the colonial agricultural areas of overseas countries; the lasting and general world problem is, however, how peoples of different habits and different standards of living and of radically different race (white and coloured), may be distributed evenly over the earth without endangering the peace and progress of mankind.

It is no longer enough to treat immigration purely as a demographic phenomenon occasioned by the decision of those immediately concerned. In order to understand the causes and effects of this phenomenon it is necessary to include in our survey the national and international measures which have been taken in the interests of the community.

I. PROGRESS OF STATISTICS

As early as the first International Labour Conference in Washington in 1919 the International Labour organization (I.L.O.) created under the treaty of Versailles passed various "recommendations" dealing with equal treatment of alien labourers and with collective recruitment of foreign workers, and appointed an international emigration commission, which produced a systematic programme of action at its session in Geneva in 1921. The 4th International Labour Conference of 1922 adopted a "recommendation" relating to the collection and improvement by the I.L.O. of statistical and other information on migration. In addition to current monthly publications of the most important data, the I.L.O. issued in 1925 a first annual report on the statistics of 60 countries and territories, *Migration Movements 1920–1923* (Geneva, 1925). This report embodies the results of exact and uniform statistical inquiries and provides an international co-ordination of statistics. The numbers and details of the migrants (sex, age, profession, nationality, country of last and future permanent residence) have been classified for the first time, in eight homogeneous groups: (1) oversea emigration of nationals, (2) continental emigration of nationals, (3) oversea immigration of nationals (repatriation I.), (4) continental immigration of nationals (repatriation II.), (5) oversea emigration of aliens (generally returning to their country of origin), (6) continental emigration of aliens (generally returning to their country of origin), (7) oversea immigration of aliens, and (8) continental immigration of aliens.

In giving these figures the report explains the very frequent variations in the method of compiling them, and definition of the "migrant" and also draws attention to the gaps and deficiencies of international comparisons. Migration movements during the periods 1909–1913–1914 had a transitional character, but those during the periods 1915–9 and 1920–4 can be illustrated comparatively. The tables on p. 908 show the overseas emigration and immigration (repatriation I.) of nationals in the chief European countries and the overseas immigration and emigration (repatriation II.) of aliens in certain countries of the world.

II. CHARACTER OF MIGRATION MOVEMENTS

Overseas migration has perceptibly declined since the War.

As regards the European countries of emigration the annual average (before the War 1,349,251 and 669,574 after the War), so far as proper statistics are available has decreased by 50·38%. In the countries composing the former Austro-Hungarian monarchy emigration has sunk to 70·4% of its pre-War figures: emigration from Italy 58·8%, emigration from Finland, 56·8%, and Portugal, 51·6% is less than ⅔ of what it was; the percentages for Great Britain are 43·6, for Spain 39·6, for Sweden 38·3, for Norway 34·7, for Belgium 31·6, and for Denmark 29·5%. Emigration has increased

1924	416,870	72,262	108,122	96,052	159,939	46,105	103,667	59,918	39,815	30,593	16,409	13,445	85,288	..
Average 1920–4	398,395	169,364	87,660	74,625	133,677	48,147	90,827	62,169	39,496	30,027	16,863	12,422	83,962	16,98

since the War by 107·5 % in Germany, 53·9 % in the Netherlands, 24·1 % in Switzerland. Thus the proportion supplied by each country to the total of emigrants has altered. Before the War the proportion of the total overseas emigration from different European countries was: Italy 30·05 %, the United Kingdom 28·86 %, Austria-Hungary 18·51 %, Spain 11·22 %, Portugal 4·48 %, Germany 1·74 %, Sweden 1·36 %, Finland 1·16 %, Norway 0·98 %, Denmark 0·61 %, Switzerland 0·41 %, Belgium 0·38 %, Holland 0·19 %. It now runs: United Kingdom 32·94 %, Italy 24·95 %, Spain 13·66 %, territory of the former Austro-Hungarian Monarchy 9·71 %, Germany 7·29 %, Portugal 4·37 %, Sweden 1·7 %, Norway 1·30 %, Switzerland 1·03 %, Finland 1·02 %, Denmark 0·88 %, the Netherlands 0·60 %, Belgium 0·53 %.

The statistics of immigration show the annual average immigration as falling from 1,720,703 in 1909–13 to 942,711 in 1920–4, five years after it, a decrease of 45·21 % falling to 46·1 % of pre-War figures in the U.S.A., 41·75 % in Canada, 40·76 % in Argentina, 55·47 % in Brazil, 87·50 % in Australia, while the figures for Mexico (6·6 %) and New Zealand (3·69 %) remained practically unchanged, immigration into Cuba rose by 122·29 % and into South Africa by 18·33 %. Formerly the United States took the largest proportion of mmigrants with 50·25 % of the total, Argentina had 15·5 %, Canada 12·20 %, Brazil 7·82 %, Australia 7·33 %, New Zealand 2·38 %, Cuba 2·20 %, Mexico 1·06 %, South Africa 0·83 %. Now the list runs: U.S.A. 42·26 %, Argentina 14·20 %, Australia 9·63 %, Canada 9·30 %, Cuba 8·91 %, Brazil 7·82 %, New Zealand 4·19 %; Mexico 1·80 %, South Africa 1·79 %.

Differences of direction (nationality of immigrants and country of ast and of future residence) are even greater than those of the total volume. This is shown by the following table for the U.S.A., which s still the most important country of immigration:

Immigration of aliens into the United States by principal countries of origin, 1913–4, 1920–1 and 1922–3.

Countries of origin	Numbers of immigrants admitted			Per cent of total		
	1913–4	1920–1	1922–3	1913–4	1920–1	1922–3
Northern and western Europe . .	164,133	138,551	156,429	13·4	17·2	29·9
Southern and eastern Europe . .	915,974	525,548	153,674	75·2	65·3	29·4
British North America .	86,139	72,317	117,011	7·1	9·0	22·4
Mexico . .	14,614	30,758	63,768	1·2	3·8	12·2
Other countries	37,620	38,054	32,037	3·1	4·7	6·1
Totals . .	1,218,480	805,228	522,919	100·0	100·0	100·0

The table above shows two tendencies. First, there is a reduction, lready considerable before the new system came into force, of total nmigration into the United States as compared with 1913–4, becom-ig more marked in the year 1922–3 under the influence of the new uota law. Secondly: in 1922–3 less than one-third of the immigrants ame from southern and eastern Europe, as against three-fourths in 913–4. The number of immigrants from northern and western urope, which was formerly about one-eighth of the total, became early one-third.

In the year 1923–4 the number of immigrant aliens increased to 06,896. The proportion of northern and western European peoples" increased from 20·8 % of the whole in 1913–4 to 55·7 % the year 1923–4 and the proportion of southern and eastern uropean "peoples" decreased from 75·6 % of the whole in 1913–4 only 27·2 % in 1923–4.

Not only the volume and direction of overseas migration move-ents, but also the character of the migrants has changed greatly. amily migration is on the decrease, outside the British Empire. he preponderance of males is greater than before the War. Accord-g to statistics from 13 countries of emigration, males composed 5·6 % of the total in 1922, 63·7 % in 1923. The same increase in the eponderance of males may be seen from the statistics of the chief untries of immigration (54·2 % and 62·4 %). This increase is due to e fact that in 1922 the states of western and northern Europe ill made little use of their quotas of immigration to the United ates, while recently the southeastern states, where family emi-ation was most common, have not been able to send the wives and ildren to join the heads of their households so frequently as before. ercentage of male immigrants to the United States was 48·4 % in 22, 58·8 % in 1923.) Even emigration from the United Kingdom as affected as regards the general proportion of the two sexes 1·9 % of males in 1922, 59·6 % in 1923). The sexes of immigrants ere most evenly distributed in South Africa and New Zealand, most evenly in Cuba, the Argentine and the other South American ates, owing to seasonal migration and the greater risk in settling. e decrease of the percentage of child migrants from 1922 to 1923 milarly points to a decrease in family migration. In the United ates the percentage of immigrant children dropped from 20·6 to 14·6; in Argentina it was only 10·4 %, in Cuba only 6·3 %. In the British Dominions the proportion rises to 22·5% (New Zealand 23·2%). Jewish immigration into Palestine has a more family character (26·7 % children in 1922, 26·9 % in 1923). Of able-bodied adults, the young are more numerous than the elderly.

The countries of emigration and immigration complain even more of the alteration in distribution of occupations. Before the War up to two-thirds of the overseas emigrants from Europe were engaged in agriculture, in 1922 and 1923 only 14·6 % and 14·0 % respectively of the total emigrants from 14 European countries were of this class. Even if domestic servants and day labourers are counted in, this class hardly amounts to a third of the total. The statistics of countries of immigration place the percentage but little higher.

In consequence of the difficulties and restrictions on immigration and unfavourable economic conditions in Europe, repatriation home of previous overseas emigrants has decreased greatly (according to Table II. with 31·96 %) and ever more rapidly. In the five years after the War repatriation to Great Britain was 18·3 % less than before the War; to Sweden 24·5 % less, to Italy actually 63·3 % less.

The loss of population through migration per 100,000 inhabitants, arrived at by calculating the difference between figures of immigrants and emigrants, gives the following table for European countries (1920–3): Portugal −1,936, Great Britain and North Ireland −1,429, Italy −1,135, followed at a distance by Spain, Sweden, Czechoslovakia, Poland and Rumania.

The figures for the five overseas countries which have recorded both emigration and immigration show that the gain in population through migration per 100,000 inhabitants is highest in New Zealand (3,906), followed by Argentina (1,826), the United States (758), South Africa (116).

III. RESTRICTION OF IMMIGRATION

The universal depression consequent on the World War could not of itself have brought about, except in a certain degree, the decrease of emigration and its change of direction. The history of migration movements, especially in the United States, shows that for a century past periods of economic depression have coincided with the lowest figures of migration. The supply of emigrants in the European countries remained greater than the overseas labour markets, especially those of the United States, could have absorbed.

United States.—The depression which set in after a brief post-War boom, in the United States as elsewhere, in 1920–1, and the great increase in immigration in 1919–20 increased the apprehension with which organised labour, in particular, had come to regard unregulated immigration even before the War. Moreover, during the War American objections on national grounds to immigrants from south and eastern Europe, who are only assimilated with difficulty, acquired decisive importance, and public opinion was converted by motives of patriotism to a policy of restriction. The clause in the consolidated Immigration Law of Feb. 9 1917 under which persons over 16 years of age who are unable to read are not admitted, proved ineffectual in reducing the undesired element and emergency legislation for the restriction of immigration combined with national discrimination was finally approved on May 19 1921, and came into force on June 2. The number of alien immigrants, in the case of each nationality, was limited to a maximum of 3 % of the number of foreign-born persons of that nationality who were resident in the United States at the time of the census of 1910. Certain categories of persons were, however, exempted from these quota.

This emergency law was to operate until June 30 1924 when the Immigration Act,[1] 1924, came into force. The earlier law had already reduced the proportion from southeastern Europe of the total immigrants by one-third. The effect of this reduction was, however, partially annulled because such persons were allowed to immigrate from the countries bordering on the United States and unaffected by this law (Mexico, Canada) even of alien origin, if they had been settled there for two years in the one case, five in the other. Thus the total immigration from Canada and Mexico rose from 66,361 for the financial year of 1922 to 290,026 for 1924. The total of immigrants had therefore not decreased. Economic depression also forced the countries of northwestern Europe to make full use of their high quotas. Clandestine immigration of southeastern Europeans by land and sea is estimated by the best authorities at 150,000 annually. Public opinion, at one with Albert Johnson, Chairman of the Committee on Immigration of the House of Representatives, in the opinion that "the melting pot was to have a rest," welcomed the new law.

---

[1] See Immigration Laws and Rules of Feb. 1 1924, issued by the U.S. Bureau of Immigration (Washington, 1924).

The law distinguishes three categories of persons:—

1. The old emigration is wound up under the first group; unmarried children under 16 and wives of previous emigrants, now naturalised, and certain other individual desirable types are allowed to immigrate *outside* the *quota*. Immigrants from the American continent do not come under the law at all. Persons who were not born there can no longer, under any circumstances, be accepted outside the quota of the country of origin.

2. As regards immigrants on the quota, the law adopts the following drastic principles for the first three years of its validity. The annual quota of any nationality shall be two per centum of the number of foreign-born individuals of such nationality resident in continental United States as determined by the United States census of 1890. After July 1 1927 the total number of immigrants is to be fixed at 150,000, the quota of each nationality being determined by the relationship between the number of inhabitants having that national origin to the total population of the United States in 1920.

On this basis the annual quotas from the principal countries are as follows:—

	1921–2	1924–5
North and West Europe		
Belgium	1,563	512
Denmark	5,694	2,789
France	5,729	3,954
Germany	68,059	51,227
Great Britain and North Ireland	77,342	34,007
Irish Free State	..	28,567
Netherlands	3,607	1,648
Norway	12,202	6,453
Sweden	20,042	9,561
Switzerland	3,752	2,081
South and East Europe		
Czechoslovakia	14,282	3,073
Italy	42,057	3,845
Poland	25,827	5,982
Rumania	7,419	603
Russia	34,275	2,248
Yugoslavia	6,426	671

3. Finally, persons ineligible as citizens of the United States fall into a separate group. This provision excludes the Japanese, the only Eastern Asiatics who had not already been excluded from the possibility of immigrating by the earlier special "Law of Exclusion" (China), or by the clause on the "barred zone" of Asia adopted into the law of 1917.

The most important result of the new immigration legislation, as compared with the period before the War, is that immigration from the most important European countries of emigration (Italy, the territories of the previous Austro-Hungarian Monarchy and Russian Empire) had been reduced by nine-tenths. The quotas from Sweden, Norway, Denmark and Switzerland have also been reduced by half; those for Germany and the Irish Free State remain practically unaltered. All other countries of emigration, including Great Britain, whose annual quota is now only 34,007, must now in increasing measure seek their outlet in other overseas countries.

Other Countries.—But South American and other countries have adopted similar restrictions on immigration for similar reasons. Before the War these countries—Brazil, Uruguay, Argentina—and others still encouraged white immigration, but they can no longer afford to do so. Not only have they paid more attention to selecting the right class of immigrant, but at times immigration has been suspended altogether. The bad conditions have led to some outbreaks of the proletariat in several ports, these being aggravated by the failures who drifted back from up-country. So in South America too only settlers with capital and able-bodied country labourers are welcomed. No state still grants free land. The minimum capital required, even by Brazil and Argentina, is too high for the unemployed of Europe, and they cannot make their way as unskilled labour in hot countries against the competition of the native coloured population (the North of South America, North and Central Africa, Asia Minor, etc.). Especially intellectuals who have tried their luck in these districts have very often come to grief.

IV. MOVEMENTS OF POPULATION IN THE BRITISH EMPIRE

Great Britain has long endeavoured to divert her surplus population from the United States, and has tried where possible to find it an outlet in her own Empire. The motives and results of these efforts, prosecuted with increased zeal since the War may be regarded as typical of the migration crisis, since the Empire contains countries of emigration and immigration which are naturally complementary, and the official interpretation of the term "migration" denotes internal movements from one of these territories to another.

Empire Settlement Act.—The importance of the settlement question for the maintenance and consolidation of the British Empire was strongly emphasised by the Dominions Royal Commission, 1911–7, but although since 1890 the theory of state subvention has often been mooted, it was not until 1921 that a scheme for state-aided imperial settlement was adopted by the Imperial Conference of that year. The Empire Settlement Act passed by the British Parliament in 1922, implemented the scheme. An Overseas Settlement Office was set up under the supervision of a Colonial Office Committee, and in 1925 a new Under-Secretaryship of Dominion Affairs was constituted, with complete charge of migration and settlement policies. Emigration departments were opened by the Dominion Governments in London. England's share of the cost of carrying through any one measure was not to exceed 50%, and the obligation to grant subsidies was not to extend beyond 15 years. The total which might be expended in one year under this was £3,000,000, exclusive of receipts from interest or repayments in later years. The scope of the law could be extended to other parts of the Empire, but in 1926 this had not yet been done. As shown by Table II., emigration to the Dominions was still less than before the War, when the broad, thinly-populated expanses of the overseas portions of the Empire had already begun increasingly to attract the stream of emigration from Great Britain in default of other labour markets. Between 1891–1900 only 28% of English emigrants went to the Colonies, the majority to the United States; between 1901–12 63% went to the Colonies, 1919–23 64%. When the American quota was reduced in 1921 84,261 out of a total of 91,262 overseas emigrants from Great Britain and Northern Ireland went to parts of the Empire.

The comparatively small financial part taken by certain Dominions in carrying through this scheme is due to economic and social difficulties. These districts need mostly agricultural settlers and labourers and female domestic servants willing to live in the country. Great Britain is, however, rather short of these classes, while the Dominions object to the immigration of the superfluous skilled industrial labourers, in view of the unemployment in their own industries and the necessity of protecting the standard of living of their own population. Objections are also raised to agricultural settlement, on the ground that this increases the agrarian losses provoked by the considerable fall of prices of agricultural produce. Then it is feared that most of the former urban elements will soon leave the land again and increase the over-preponderance of the towns which is already very great. The first step should be to settle the urban unemployed of the overseas districts on the land, since they are already used to local conditions. And so all these states, although some have had satisfactory experience with immigration, have imposed strict conditions of selection of human material from the mother-country, or insist on suitable preliminary training for settlers. Families and juvenile emigrants are much preferred. New Zealand and Canada have been comparatively accommodating. Canada, however, has not an exclusively Anglo-Saxon population to increase and makes efforts to attract agricultural labour from other European states as well. South Africa is in general opposed to all European immigration, as she is suffering particularly from unemployment and has native labour to spare.

The British Problem.—The school of Mr. J. M. Keynes holds that the present unemployment in Great Britain is intensified by the fact that 1,000,000 persons remained in Great Britain during the War who would otherwise have emigrated, and considers that the maintenance of the standard of living in the mother-country could only be ensured—imperfectly—by increasing emigration, or more safely, by reducing the birth-rate; but other experts (Sir William Beveridge and Professor A. L. Bowley) are more optimistic—they calculate that after 1931 the decline in births during the War will result in a shortage of productive labour in England, on the assumption that emigration again reaches its pre-War dimensions, the death-rate remains unaltered and the participation of women in the work of the community remains constant. The Overseas Settlement Committee think that it will be possible to secure an adequate outlet by emigration within the Empire for the surplus industrial workmen of the mother-country, although used to a high standard of living and the state unemployment allowance, as soon as world conditions have got back to normal and the agrarian crisis has been surmounted. The financial assistance of emigration by the mother-country should, in any case, further the industrial development of the Dominions and help the overseas portions of the Empire to become self-supporting.

V. LEGISLATION ABOUT EMIGRATION

Before the War freedom of emigration was almost general. Judging by the legislation of the most important countries of emigration, such as Italy, the general character of emigration policy was as follows: emigration was only restricted in the case of persons who had to be kept in the country on account of military service, criminal records or immaturity. Further, persons were prevented in their own interests from emigrating if they did not fulfil the conditions of the countries of immigration, if they possessed insufficient means or ran the risk of getting into an unfavourable position by paid passages or other concessions. In order to protect the emigrants only such shipping companies were allowed to carry them as were under supervision, so as to avoid the activities of secret agents. A special emigration fund was maintained out of various sources which created an emigration authority with local and foreign branches and established or supported special welfare institutions in the ports and elsewhere (emigrants' homes, labour registries). But according as the character and social spirit of the government was more or less democratic, so, in practice, there was more or ss hostility towards emigration. These principles of emigration olicy were upheld in post-War legislation, and supplemented by fiscal measures and by various restrictions in the recruiting emigrants.

The impoverished countries of the continent of Europe encountered even greater difficulties than did the British Empire om the attitude of the countries of immigration. In spite of the eat and constantly recurring unemployment, it was impossible let millions emigrate, as had been generally expected after the War. The governments of the emigration states were themlves at first swayed by contradictory motives. Where the military motive no longer weighed in the balance, they were xious not to increase the price of labour through emigration, as not to hamper their export trade, or they wished to settle eir surplus population at home by agrarian reform. People were mistrustful, and expected, too, a great economic wave of osperity. Soon, however, certain countries were forced by eir great surplus of population to give direct state encouragement and assistance to emigration, but everywhere they found ors shut against them. The example of conscious national igration policy is Italy. So long as she is forced to place her our at the service of foreign economic systems, she tries nerally to get a suitable return for it (policy of valorisation), increase the value of her labour by suitable training, in rticular not to permit collective recruiting of emigrants except der conditions dictated by the state, to protect the interests of emigrants against the transport companies and other agents ring and after emigration, to preserve the sense of nationality by suitable organisations in the country of immigration (policy of schools, clubs and voting) and finally to place the whole organisation of emigration under a state general commissariat for emigration and its organs.

A whole series of countries of emigration have copied Italian legislation more or less closely since the War in their new emigration legislation. As passports and visas are still compulsory, it is possible to regulate emigration policy towards the different states. All European countries are endeavouring more or less to get their own unemployed industrial labour out of the country where possible, and to shut themselves off from foreign labour at the same time.

Statistics show that countries of emigration have been able to divert their surplus population overseas most easily where the movement is favoured by racial kinship and political interests. Most of the Germanic and Nordic states of Europe were still able to turn to the United States up to 1924 even in greater measure than before the War. The Latin and Slav countries, being almost excluded from North America, compensated themselves mostly in the South American states. So, to take 1924 as an example, 52·5% of the Italian, 44·7% of the Spanish, 37·4% of the Czech emigrants went to the Argentine. The attempts of the Italians and Greeks to get a footing in the British Dominions and South Africa had, however, very little success.

VI. MIGRATION OVER LAND FRONTIERS

Overseas emigration would never have succeeded in satisfying the urgent demand for emigration. Fortunately the European states were able to find an outlet in a few European countries, especially France, Belgium and Luxembourg.

Immigration into France.—France was impoverished in man power, and her labour market, in consequence of the work of reconstruction and the increase in her export industry resulting from the fall of the franc, was able to absorb foreign labour to an extent which varied, but on the whole increased. Statistics of continental migration are still very imperfect, but show great changes since the War. Before the War Germany received about a million continental immigrants, France comparatively very few. This immigration to Germany was almost entirely agricultural and mostly seasonal and non-permanent. In 1924, however, Germany admitted no foreign industrial labourers and only 29,196 agricultural workers, while French national statistics, taken on the frontiers and certainly some 50% too low, show the figure of continental immigrants at 262,877 in 1923 and at 223,495 in 1924. The great majority came from Italy, which now sends two-thirds of its emigrants to France; but there is hardly a country in Europe which has not sent labourers, mostly industrial, in large numbers to France in recent years. Continental migration has the advantage for the countries of emigration that it easily alters its character and often helps to increase technical knowledge.

Regulation.—But the countries of immigration are confronted not only with difficult economic and social problems, but also with problems of national health and security arising out of these mass immigrations. It has proved especially necessary to regulate the national labour market as elastically as possible, so that at any given moment only so much foreign labour as is barely necessary remains in the country. It has proved possible to adapt *collective* migration to the needs of the present labour markets by means of state treaties, and to regulate the legal and social position of those concerned in a proper way. But the good results thus attained have been largely nullified by the insufficient regulation and supervision of individual migrants. The pressure of unemployment has also caused the Central European countries to put severe limitations on the entry and settlement of foreign labour. Certain countries even expel labourers who have long been resident in the country. The resultant insecurity and the rise of prices increases the difficulties of reconstruction caused by tariff policy, etc.

Continental emigration, for example, into undeveloped Russia, is only permitted to agricultural settlers with capital ready to form model settlements in the north. On the other hand, emigration out of European Russia into Siberia has assumed extraordinary dimensions since the War. The chances of normal continental exchange of labour would have been much greater but for the emigration to Western Europe of Russian refugees. Japan and China are now themselves largely reduced to continental migration within Asia, since their only overseas outlet is now South America. Continental migration in the interior of Africa has also assumed very great importance, and in South Africa especially, the various states have regulated it from a one-sided point of view.

There must be general state regulation for crossing of frontiers and settlement of foreigners. Great Britain, thanks to her insular position has been most successful in this since the introduction of compulsory passports. The German "Labour Centre," which works by compelling foreign hired labour to obtain permission and register, has been much less successful. France is only now beginning to attack the problem by a more exact control of identification cards, unification of the administration (Commission de la main et l'oeuvre étrangère 1924) and a long-promised legal regulation of conditions of immigration.

VII. GENERAL INTERNATIONAL REGULATIONS

The recognition of the necessity of reconciling conflicting interests in migration has led those European states which are subject to continental exchange of labour to make a beginning and conclude comprehensive migration treaties (France with Czechoslovakia, Poland and Italy). But the experience so gained is not enough to allow one simply to apply these methods of regulation internationally to world migration. The development appears here to overlook the regulation of social-political questions of detail. The International Labour Office, which has been entrusted with this task, has declared in principle for equal treatment for foreign labourers in all respects, and in detail has begun by regulating for equal treatment of foreign workers as regards workmen's compensation for accidents during work (1924). The social-political regulation touches on many other questions, notably protection of migrants (especially women and juveniles) and the regulation of the labour market. The programme worked out by the International Emigration Commission 1921 was widened and revised in many respects by the technical Interstate Conference summoned in 1924 by the Italian Govt. and attended by delegates from 57 governments. The Protocol of this conference shows the great number and variety of these problems. The agenda dealt mainly with technical matters; the transport of emigrants, hygiene and sanitary services, assistance at the ports of embarkation and disembarkation, assistance for women and children, information on employment in the countries of emigration, and the principles to which migration treaties should conform, etc.

The actual conditions of emigration and immigration in the different states touch the sovereignty of the states so nearly that most governments at present refuse to admit international regulation. This was shown very clearly by the United States House of Representatives when passing the Immigration Law of 1924. Even the different international federations of Trades Unions have not succeeded in arranging mutual co-operation. It may, however, yet prove possible to secure the collaboration of the states whose interests conflict, and thus eliminate dangers to the peace of the world. Private leagues for the protection of the emigrants are already doing good work towards bringing about a rapprochement of public opinion in different countries on questions of migration. These leagues joined in a common international conference held at Rome in May 1924.

The increase of open and secret emigration from Canada and Mexico into the United States shows that unless continental migration be regulated, the intentions of legislation regarding overseas migrants will merely be paper regulations. Either America must make up her mind to establish an effective frontier police, to register and keep continual track of foreigners, or she will not be able to stop the impulse of the peoples to immigration. In the former case her attraction for the already assimilated elements of Canada and Mexico will grow and the number of territorial disputes over this question will increase; in the latter there will be an intensification of the shortage of labour and high wages.

The Oriental Question.—The problem of Oriental immigration into the United States is of special urgency. Under the "Gentleman's Agreement" of 1907 freedom was given to the Japanese Govt. to issue passports to Japanese labourers who had been resident in the United States before the conclusion of the agreement and were seeking re-entry, and also to parents, wives and minor children of Japanese already resident in the country but the Japanese Govt. pledged itself not to issue passport to all other Japanese nationals seeking entry into the Unite States as labourers. This pledge appears on the whole t have been loyally observed by the Japanese Govt., but i practice it afforded certain loopholes for evasion; the numbe of Japanese residents continued to rise steadily and the agitatio in California against their entry increased.

The Gentleman's Agreement was superseded by the Immigration Act of 1924, which declared that no "alien ineligibl to citizenship" should be admitted to permanent residence i the United States with the exception of certain specified categories, comprising approximately the classes contemplated unde the Gentleman's Agreement. It was decided by the Suprem Court that all aliens who are not white and of European origi or black and of African origin—*i.e.*, essentially all Asiatics—ar ineligible to citizenship, excepting those specifically exempted b the Act itself. The political effect of this measure was profound It substituted a unilateral action based on domestic legislation fo an international agreement, and Japanese national honour wa wounded by an action which directly discriminated agains the Oriental races. The Japanese Govt. protested strongl and proposed that Japanese immigration should be regulate like that of other foreign countries by the quota system. Thi proposal was rejected by the United States Senate, and th discrimination was upheld. After a brief period of acute agitatio in Japan excitement subsided, but the problem remains.

In British Columbia, Japanese immigration is still regulate by a Gentleman's Agreement, but there has grown up an agitatio in favour of legislation on the model of that passed in th United States. The British Empire is thus acutely concerned i this question. The British Empire had its own very delicat inter-Imperial problem arising out of the attitude of the popula tions of certain Dominions towards Indian immigration Australia views any settlement of Asiatic peoples with dis favour, while in South and East Africa the discrimination in th treatment of Indian nationals under domestic legislation ha seriously prejudiced political relations between these countrie and India.

MIHALACHE, ION (1882–), Rumanian politician, wa born March 3 1882, of a poor peasant family. He became village school teacher and distinguished himself as an organise of the Village School Teachers' Federation, of which he wa eventually appointed president. In 1914 he entered politics, and after the World War founded the Peasant (Tsaranist) party first in Bessarabia, and then extended its organisation to the rest of the country. In the first elections held after the War in 1919, the Peasant party won 70 seats in the Chamber of Deputies and Mihalache was appointed Minister of Agriculture in the Vaida-Voevod Cabinet, which office he held until March 1920, when Vaida-Voevod resigned with the entire Cabinet. Mihalache distinguished himself during the World War in which he served with the rank of captain. In addition to the highest Rumanian military decoration (Michael-the-Brave) he was awarded the Legion of Honour, the Order of St. Stanislas and other foreign decorations.

MILAN (*see* 18.437), the second largest town in Italy and the most progressive commercially and industrially, had a population of 712,844 in 1921. The old quarters are giving way to blocks of new buildings, and the circumference of the city in 1926 was about eight miles. Barracks have been erected and exercise grounds made outside. The manufacture of motor-cars and artificial silk are growing industries. A free university was opened in 1924. In 1918 the royal palace to the south of the cathedral was presented to the municipality by the Crown. The Home of Rest for musicians, established by Verdi, has been transformed into a Verdi Museum, and a statue of the composer was unveiled in front of it in 1913. The Museo del Teatro, opened in the building of the famous Della Scala theatre in 1913, contains a collection relating to its history. A larger station, fronting the Piazza Doria, to replace the central railway station, was under construction in 1926.

MILES, NELSON APPLETON (1839–1925), American soldier (*see* 18.442), died at Washington, D.C., May 15 1925.

MILFORD HAVEN, LOUIS ALEXANDER, 1ST MARQUESS OF (1854–1921), British sailor, was born at Gratz May 24 1854, the eldest son of Prince Alexander of Hesse, by his morganatic marriage with the Russian Countess, Julie Thérèse von Haucke. As Prince Louis of Battenberg he was naturalised as a British subject in 1868 and entered the royal navy in the same year. In 1884 he married Princess Victoria, daughter of the Grand Duke Louis IV. of Hesse. From 1891 to 1894 he was naval adviser to the inspector-general of fortifications and in 1900 was appointed assistant director of naval intelligence at the Admiralty, being made director in 1902. In 1904 he was promoted rear-admiral and after serving as second in command in the Mediterranean was made vice-admiral in 1908. After commanding the Atlantic and Home Fleets, he was in 1912 appointed First Sea Lord of the Admiralty, but in Oct. 1914 he was compelled to resign from this position owing to public resentment at his German origin, which persisted in spite of his fine record of service. In 1917 he relinquished his German title, assumed the surname of Mountbatten and was elevated to the peerage as marquess of Milford Haven. In the following year he retired from the active list of the navy. He became an admiral of the fleet in 1921 and died on Sept. 11 of the same year.

MILITARY RAILWAYS: *see* LIGHT RAILWAYS, MILITARY.

MILK AND DAIRY PRODUCTS.—The dairy industry is in many countries the chief agricultural industry and in all countries s of the utmost importance to agriculturists. The fact that this s recognised by agriculturists themselves is evident from the rapid expansion in some countries of the dairy herds. The following statistics give some indication of such expansion and of the state of the industry in various countries:—

The Production of Milk

Great Britain.—In 1924 the total milk production was approximately 1,300 million gal. (less milk used for calf rearing). Of this, 500 million gal. were consumed as liquid milk; 500 million gal. were consumed in the manufacture of butter and cheese; 35 million as condensed milk and 61 million as cream, etc. The dairy herd numbered 3,111,000.

Australia.—In 1921, 267 million lb. of butter and 32½ million lb. of cheese were produced. The dairy herd numbered 2,343,221, with an average production per cow of 343 gallons.

Canada.—In 1921, 236½ million lb. of butter and 149¼ million lb. of cheese were produced. The dairy herd numbered 3,736,832.

New Zealand.—In 1924, 71½ million lb. of butter and 161 million lb. of cheese were exported. The dairy herd numbered 1,291,000.

United States.—In 1923 the total milk production was 109,736 million lb., of which 54,614 million lb. were consumed as liquid milk. 39,106 million lb. were consumed in the manufacture of butter, and 12,714 million lb. in the manufacture of cheese, condensed milk, ice cream, etc. The dairy herd on Jan. 1 1924 numbered 24,675,000, but this number had decreased in 1925 to 20,965,423.

Argentine.—In 1918, 41,863,000 lb. of butter and 14,177,000 lb. of cheese were exported. The dairy herd numbered 2,378,000.

Denmark.—Denmark is the main European exporting country of dairy products. In 1921, 199,500,000 lb. of butter were exported; the dairy herd numbered 1,184,268.

The Consumption of Milk

The consumption of milk and dairy products varies as much as production. In a survey of 68 American cities which have populations of over 100,000, the consumption of fluid milk was found to be ·66 pt. per head daily. In 1924, in the New York Metropolitan district, where there is a population of about 8·7 million the consumption per head was ·75 pt. daily, an increase of 85% during the preceding 30 years, due largely to improved quality. The following statistics collected by the United States Department of Agriculture give the annual average consumption per head of liquid milk, butter and cheese in various countries:—

Annual Consumption per head of liquid milk (In American Gallons).

Denmark in 1914	68·5 gal.
America in 1925	53 gal.
Canada in 1916	26 gal.
United Kingdom in 1918	22 gal.

Annual Consumption per head of butter.

Canada in 1911	27·7 lb.
Australia in 1913	25·6 lb.
New Zealand in 1914	21·7 lb.
Denmark in 1914	19 lb.
United Kingdom in 1914	17 lb.
United States in 1919	16 lb.
Argentine[1] in 1915	1·8 lb.

Annual Consumption per head of cheese.

Denmark	12·3 lb.
United Kingdom	11·2 lb.
United States	4·2 lb.
Australia	3·63 lb.
Canada	3 lb.
New Zealand	3 lb.
Argentine	2·9 lb.

[1] Factory butter only.

Production and Consumption in Great Britain.—It will be seen from the figures given above of the consumption of milk in the various countries that Great Britain's consumption is low compared with that of other nations. In 1918 the returns of the consumption of liquid milk were obtained through the local food control committees and it was found that these varied from as low as 0·10 pt. in Inverness to 0·31 pt. in London, an average for the whole area being 0·25 pint per head per day. Actual consumption would be above these figures as milk produced and consumed on farms does not appear, whereas the figures include the total population. The London figures would be approximately correct but the production of milk in Great Britain in recent years has not kept pace with the increase in the human population nor with the demand by the latter for milk products. This is shown by the following table extracted from the report of the Astor committee:—

	1871	1914	Increased Percentage
Population	26,100,000	41,700,000	60
Numbers of cows and heifers	2,091,000	2,937,000	40
Weight of cheese imported; cwt.	1,216,400	2,373,091	95
Butter imported; cwt.	1,334,783[1]	3,882,116	304
Margarine imported; cwt.	. .	1,501,520	. .
Condensed milk imports; cwt.	352,332[2]	771,239	128
Dried milk imports; cwt.	. .	30,601	. .
Total weight of Dairy produce Imported—cwt	2,903,515	8,558,567	235

[1] No separate statistics for butter and margarine before 1888.

[2] No separate statistics for condensed or dried milk before 1888.

The relative consumption of milk in Great Britain is much lower than is desirable in the national interest. This is probably due to the fact that it is known that the quality, as regards cleanliness, has been gravely defective and there is no doubt that the larger consumption in other countries is primarily due to a cleaner supply. During the past few years, however, there has been a distinct improvement in the methods both of production and distribution in Great Britain, and as a result it is safe to say that the consumption of milk is gradually increasing and there can be little doubt but that the educational work which has been carried on since 1915 is beginning to have its desired effect.

Imports of Dairy Produce Into Great Britain.—The value of dairy produce imported into the United Kingdom has also steadily risen for the last 50 years until in 1914 it reached a total of £38,000,000. Of this over £27,000,000 was paid to Denmark and Russia for butter and Holland for cream, cheese and condensed milk, whilst the balance, amounting to over £10,000,000, was paid to Australia and New Zealand for butter and to Canada and New Zealand for cheese. It will therefore be seen that Great Britain is anything but self-supporting in its dairy industry whilst many other countries have an exportable surplus. The reasons for the relative importance of dairying probably differ from country to country but in addition to any particular reasons which any country may have there has undoubtedly been a widespread recognition in most lands of the great value of the dairy cow as a producer of human food. As land, labour and feeding stuffs have increased in price, the dairy cow has more and more displaced the strictly meat-producing farm animals as an economical agent for the conversion into human food of those field crops which are not suitable for direct human consumption.

PURITY OF SUPPLIES

Importance of Milk as a Food.—Most dietetic authorities are satisfied that milk is the most important individual foodstuff and that an abundant supply of milk of good quality is an important factor in the health of a nation, and especially of city dwellers. Milk contains all the nutritive constitutents required by the body—proteins, fats and carbohydrates—in a readily assimilable form, and possesses special properties which promote growth and maintain the body in a healthy condition. It is therefore a valuable food for all classes of the community and especially for children. These special qualities in milk were first made known by Prof. F. G. Hopkins of Cambridge and have since been the subject of research by numerous investigators, notably Professors T. B. Osborne and L. B. Mendell of Yale University and Prof. E. V. McCollum of Johns Hopkins University. The exact nature and composition of these growth-promoting substances or vitamins is at present unknown, but their existence is inferred from the effects produced in respect of growth and health by feeding animals on special and carefully controlled diets.

Investigations into this subject indicate the existence of at least three vitamins, all of which are present in milk. These have been termed: (1) The ricket-preventing vitamin (or fat soluble A) which is necessary to promote growth and to prevent rickets in young animals.[1] The fat of cream and butter are amongst the richest known sources of this vitamin. (2) The anti-neuritic vitamin (or water soluble B) which is also necessary to promote growth, and in addition is essential to prevent the occurrence of the disease known as beri-beri. This vitamin is found in the germ and in the bran or outer layers of certain grains and in milk. (3) The scurvy-preventing vitamin. This vitamin is found in fresh, untreated cow's milk and in fresh fruits and vegetables.

There is no evidence that heating of milk destroys the vitamins described in (1) and (2), above. The scurvy-preventing vitamin (3), above, is however sensitive to exposure to heat, and therefore dried, pasteurised, boiled or condensed milk may be regarded as inferior in varying degrees to raw milk in scurvy-preventing properties. Skimmed or separated milk is deficient in the ricket-preventing vitamin referred to in (1), above, and the development of rickets may follow from its extended use in the feeding of young children unless the deficiency be made good. Attention may here be called to the inferiority in this respect of margarine to butter as a source of fat in the diet of growing children. Margarine is, as a rule, manufactured largely from vegetable oils. These are deficient in the ricket-preventing vitamin and the nutritive value of margarine made from such oil is therefore inferior to the nutritive value of butter. Although vegetable fats and oils are deficient in this vitamin which is also essential to growth, yet the green parts of plants are the chief ultimate source of this vitamin. For this reason the diet of cows, especially of those whose milk is to be used for infant feeding, should contain an abundance of the green parts of plants and there is evidence[2] showing that the milk given by cows in the summer, when the diet consists of fresh, green pasture, is richer in vitamins than in winter when the chief foods are hay, straw, roots and concentrates.

Need for Healthy Cattle.—Healthy cattle are the first requisite for a safe milk supply. Physical inspection by a competent veterinary surgeon will go far towards the elimination of those cows suffering from obvious disease but cannot be relied upon for anything like complete protection. The tuberculin test is more searching with reference to this particular disease. There are only two practical ways in which tuberculosis may be eradicated from a herd, namely, (1) the slaughter of all reactors; (2) the isolation of reactors and the separation after birth of calves born of reacting cows. Both methods raise many practical difficulties and it is therefore worth noting that the English Ministry of Agriculture has reintroduced the tuberculosis order giving compensation for cows slaughtered when suffering from this disease. Although it is admitted that a "considerable amount of tuberculosis of childhood is to be ascribed to infection with bacilli of the bovine type transmitted to children in meals consisting largely of the milk of the cow,"[3] at the same time it is not desirable to create unnecessary alarm by exaggerating the extent of human tuberculosis due to bovine infection. There can be little doubt that much infantile debility, leading to susceptibility to many diseases, including tuberculosis, is due to inadequate milk consumption. All reacting cows do not necessarily give tuberculous milk, and risk from tuberculous milk may be negatived by efficient pasteurisation (see *Lancet*, Jan. 30 1926).

Milk Grading Rules.—There is no question that the adoption in America of the principle of grading milk has resulted in a great improvement in the general supply. As supplied under the regulations of New York City four grades of milk are permitted. Grade A Raw includes the so-called certified milk which is produced under permit and certification by the county medical association. It also includes any other milk meeting the requirements, the principal requirement being the tuberculin test. The other grades do not require tuberculin tests and have progressively less stringent requirements as to bacterial content (taken as a measure of general cleanliness), cooling and age. Grade B is not recommended for children but is considered safe for adults. Grade C is sold to bakers and others for use in cooking. The effect of the grading rules, under which the producer receives more money for the higher grades, has been to raise the general standard of the city supply without arbitrarily cutting off the lower grades from their proper market.

In England the grading of milk has also been adopted, and table on p. 915 gives the standards required under the terms of the Milk Special Designations Order, 1923, for the various designations which it is illegal to use in connection with the sale of milk except under licence granted by or under the authority of the Minister of Health.

The clean milk competitions which have taken place in Great Britain have had a very great influence in improving the production of milk and the standard of production is probably as high in Great Britain as elsewhere. The first clean milk competition was held in Essex in 1920, and in 1925 no fewer than 33 counties

British Definitions of Grades of Milk

Designation	Herds	Bacterial content		Other conditions
		Maximum number of bacilli per cubic centimeter	Coliform bacillus	
Certified	Tuberculin tested and physically examined at regular intervals	30,000	Absent in 1/10 cubic centimeter	Bottled on the farm, name of farm, day of production and word "Certified" on each bottle cap
Grade A Tuberculin Tested	Tuberculin tested and physically examined at regular intervals	200,000	Absent in 1/100 cubic centimeter	Delivered to consumers in (a) the bottles or the sealed containers as received from the farm; (b) suitable containers of not less than two gallons capacity; (c) bottles with the name of the dealer by whom the milk was bottled, the address of the licensed bottling establishment, the day of production and the words "Grade A Tuberculin Tested" or "Grade A" on each bottle cap
Grade A	Physically examined at regular intervals			
Pasteurised Milk				
Grade A Pasteurised	Grade A milk that after pasteurisation, as required by the Minister of Health, contains not more than 30,000 bacilli per cubic centimeter and no coliform bacillus in 1/10 cubic centimeter. All other conditions as required for Grade A milk			
Pasteurised	Any milk that after pasteurisation, as required by the Minister of Health, contains not more than 100,000 bacilli per cubic centimeter. No requirement for bottling			

ndertook such competitions. More would have done so had not been for the outbreak of foot-and-mouth disease.

THE DISTRIBUTION OF MILK

While improvements in production have taken place during ne last few years methods of distribution have also shown proression, and this has been due mainly to two factors—pasteuriation and bottling.

Pasteurisation.—No reasonable amount of inspection or boratory control over a raw milk supply can provide a sufficient afeguard against the transmission of disease through milk. his fact is emphasised by milk-borne epidemics which have neir sources in carriers or unrecognised cases of disease—hence ne use of pasteurisation. Pasteurised milk has now been defined y the Ministry of Health as milk which has been heated to a mperature of not less than 145°F and held at that temperature r at least 30 min. and afterwards immediately cooled. The merican cities, however, have adopted a minimum temperature 142° F for 30 minutes. If milk be overheated the line of dearcation between the cream and the milk becomes indefinite nd the milk is then less attractive to the consumer. Pasteurisaon must never be regarded as a substitute for clean milk roduction and cleanliness in handling milk, which are the most nportant of all conditions affecting the milk supply, yet it does ve an added safeguard to the consumer in protecting him from ose diseases which may be milk-borne from human sources.

Bottling.—The second most important advance made in disibution is the delivery of milk in sealed bottles. The improveent in delivery resulting from this method will be still more arked when the present draft order, made by the Minister of ealth under the powers of the 1925 Milk and Dairies Act, rbidding the bottling of milk elsewhere than in a properly uipped dairy, becomes law. There is still room for the educaon of milk producers, milk distributors and consumers, and the ntinuance of clean milk competitions is of the greatest imrtance as a means of educating the farmer to the necessity of) healthy and clean cows, (b) healthy and clean milkers, (c) operly sterilised equipment and (d) covered milking pails. ne need for the provision of free instruction to the general blic of the value of milk as a food, the influence of a good or d supply of milk on the life and health of children and the mmunity as a whole, and the best methods of handling and oring milk in a consumer's home, is still urgent. Had the neral public been educated in the past in this respect there ould now probably be a greater demand for milk, produced d handled under better conditions, and, with the demand, a llingness to pay for milk of guaranteed cleanliness. Such ucational work should be on the principle of enlightening, and t frightening the general public.

Condensed and Evaporated Milk.—Sweetened condensed milk, the condensed milk of commerce, is officially defined in the United States as the production resulting from the evaporation of a part of the water from whole milk. It must not contain less than 28% of milk solids, including not less than 8% of milk fat. It usually contains about 40% of added cane sugar. Evaporated milk or unsweetened condensed milk must contain not less than 25·5% of total solids including 7·8% of fat and no added sugar. In Great Britain, under statutory rules and orders made by the Minister of Health, full-cream unsweetened condensed milk must contain 31% of milk solids including not less than 9% of milk fat. Full-cream sweetened condensed milk must contain the same percentage of milk solids and of milk fat. Skimmed unsweetened must contain 20% of milk solids and skimmed sweetened 26%, while all skimmed milk must be labelled "unfit for babies." The amount of imports of condensed and evaporated milk into Great Britain has increased from 26¾ million pounds in 1888 to 251 million pounds in 1925 and, unfortunately, a very large proportion of this increase is due to the importation of condensed skimmed milk.

Dried Milk or Milk Powder.—Dried milk or milk powder is a dehydrated product of milk containing about 5% of moisture. It is used as a substitute for milk in the kitchen and extensively by bakers and confectioners. Either whole milk or skimmed may be desiccated, but the skimmed milk powder will keep almost indefinitely, whereas the whole milk powder has a tendency to become rancid. It is reported that in most processes of manufacture this difficulty has been overcome. The milk is evaporated upon revolving metal drums, internally heated, or by being sprayed into a chamber through which hot air is blown. The drum processes are carried out however at normal atmospheric pressure or in partial vacuum. In Great Britain dried milk is subject to the following requirements: milk described as dried full-cream milk must contain not less than 26% of milk fat. Milk described as dried ¾-cream milk must contain not less than 20%, milk described as dried ½-cream milk must contain not less than 14% and milk described as dried ¼-cream milk must contain not less than 8%.

(E. B, PH.; A. D. A.)

MILLAY, EDNA ST. VINCENT (1892–), American author, was born at Rockland, Me., Feb. 22 1892, and was educated at Vassar, graduating in 1917. Her work, distinguished by delicacy of sentiment, placed her in the front rank of American contemporary poets. She was awarded the Pulitzer Prize in 1923 for her poem *The Harpweaver*.

She published *Renascence and Other Poems* (1917); *Figs from Thistles* (1920); *Second April* (1921); *Aria da Capo* (1921); *Two Slatterns and a King* (1921); *The Harp-Weaver and Other Poems* (1923); *Lamp and the Bell* (1923); and *Distressing Dialogues* (1924).

MILLER, JOAQUIN (1841–1913), American poet (*see* 18.464), died at Oakland, Cal., Feb. 17 1913. In compliance with his last wishes his body was cremated and the ashes taken up into the Sierras and cast to the winds.

MILLER, OSKAR VON (1855–), German engineer, was born in Munich May 7 1855. After studying electrical technology he became director of the Deutsche Edison Gesellschaft (German Edison Company) from which developed the Allgemeine Elektrizitäts Gesellschaft (the A.E.G., or General Electric Co.). He advocated the full utilisation of electricity by means of propaganda in connection with long distance cables, and wrote articles on the supplying of towns with electricity (1896–1903). He was director of the electrical exhibition, Frankfort-on-the-Main, held in 1891 when the first high tension alternating current power-transmission apparatus was installed. The transmission was accomplished over a distance of 180 km. (from Lauffen on the Neckar to Frankfort) and with only 25% loss. These experiments were of the highest importance in the development of modern electric-technology. He promoted the development of Bavarian water power as well as a systematic electric supply for that country, and was the founder and organiser of the German museum for natural and technical science in Munich.

MILLERAND, ALEXANDRE (1859–), French politician (*see* 18.465). M. Millerand, now only a private member, threw himself into his work as a barrister, and appeared in many important civil cases. In the Chamber he was a fierce opponent of the Combes ministry, which succeeded that of Waldeck-Rousseau; for he objected to its narrow and fanatical anticlericalism. In July 1909 he became Minister of Public Works in M. Briand's first Cabinet, his principal achievement at this time being the re-organisation of the state railways. Together with M. Briand he took strong measures to suppress the railway strike of Oct. 1910. In Jan. 1912 he was appointed Minister of War under M. Poincaré. His promotion surprised no one, for he had always taken a keen interest in questions of military organisation; and when the menace of Germany increased, he devoted himself to strengthening the national defences. He re-organised the higher command, and by the Act of May 29 1912 he gave a definite status to military aeronautics for the first time. In Jan. 1913 a personal incident brought about his retirement. On Aug. 25 1914 he was invited by M. Viviani to take the place of M. Messimy as Minister of War; and during the terrible situation which then prevailed he had constantly to take the initiative, for example, in attempting to remedy as far as possible the shortage of munitions. He was accused, however, of being too slow in providing the necessary heavy artillery, and he resigned with the other members of the Viviani cabinet at the end of Oct. 1915. In 1918 he was elected a member of the Académie des sciences, morales et politiques.

A few months after the conclusion of hostilities, on March 21 1919, M. Millerand was appointed commissioner general for Alsace-Lorraine. The problem of reuniting with the mother-country two provinces which had been torn from her in 1871 was a most serious one. For 50 years they had been under an administration widely different from that of France. A period of transition, therefore, was essential, alike from the point of view of political expediency, administration, economics and finance. The first French officials sent to Strasbourg had not been equal to their task; and for this reason it was essential to appoint a statesman of eminent authority with power to act, who would keep in constant touch with the Government. This post was filled by M. Millerand with complete success. In an important speech delivered in Paris on Nov. 15 1919, on the eve of the elections, he outlined the policy of the coalition which, under the name of the *bloc national*, was returned to power. On the resignation of M. Clemenceau, Jan. 18 1920, M. Millerand was chosen to form a Cabinet, and became both Prime Minister and Minister for Foreign Affairs. His main activities were in regard to the application of the Treaty of Versailles; and in orde to force Germany to fulfil her obligations, he ordered the provisional occupation of Frankfort. He was present at the inter-allied conferences at San Remo and Spa, in April and July 192 and in Aug. of the same year he met Mr. Lloyd George a Hythe. The situation in regard to Poland, who had been attacked by the Bolsheviks, now became grave, and M. Milleran therefore sent to Warsaw a contingent of French officers unde General Weygand. With this assistance the Poles gained a complete victory over the Bolsheviks. M. Millerand about this tim officially recognised the anti-Bolshevik government of Gen Wrangel, who was soon after completely defeated. In Franc itself, in May 1920, he frustrated various attempts, especiall by the railwaymen, to organise revolutionary strikes.

In Sept. 1920 M. Deschanel, President of the Republic, wa forced by ill-health to resign. M. Millerand was elected as hi successor, and out of 892 votes cast, no fewer than 695 wer given in his favour. During his candidature, he made it know that if he were elected, he intended to exert a more powerful influence on the policy of the Government than his predecessor had done. He refused to admit that his office of President force him to comply with a tradition of which he disapproved, by remaining absolutely neutral in politics. He made it clear that h intended to watch closely the foreign policy of the Government and made no secret of his wish to strengthen the power of th President by a revision of the constitution which would modif the conditions of his election; and he put his ideas into practice by frequently intervening in diplomatic negotiations. Durin the inter-allied conference at Cannes in Jan. 1922 he despatche a telegram expressing dissatisfaction at the conduct of affairs which caused M. Briand to return to Paris, and, in fact, brough about his resignation. Working on the same lines, he summone to the *Elysée* the prefects, or chief administrative officers of eac department from all over France. In a powerful speech at Evreu in the Spring of 1923 he declared that he would not agree t the re-introduction of the *scrutin d'arrondissement*, and showe marked favour to the adherents of the *bloc national*, who ha been in the majority in the Chamber since the elections of Nov 1919, and against whom the radicals and socialists were the carrying on a campaign of public meetings.

M. Millerand's conception of the rôle of President of the Republic brought him into collision with the radical and socialis majority, which, under the name of the *cartel des gauches*, wa successful in the elections of May 11 1924. He was violentl attacked by the radical socialist press, which accused him o having exceeded his powers by intervening in the party struggle and called for his resignation. M. Herriot, the leader of th *cartel des gauches*, when asked by M. Millerand to succeed M Poincaré as Premier, announced that he would do so only o M. Millerand's resignation. The latter replied that he had bee elected for seven years, and that the alteration of the party i power could in no way affect his constitutional position no abrogate his rights. But he made it clear that he had not th slightest intention of obstructing the new Government, an that its leader could count on his impartiality. M. Herriot, however, remained immovable; and M. Millerand therefore invite the Senator M. François-Marsal, who had been his Ministe of Finance in 1920, to form a Cabinet. M. François-Marsal declared in the Chamber that the attacks on M. Millerand wer contrary to the constitution, and that it was in order to uphol the latter that he had agreed to take office. His Government however, was immediately defeated; and M. Millerand tendere his resignation, protesting meanwhile against the illegality of th action taken against him. The attitude of the party in powe dissatisfied the Senate, which, as a result, voted with the opposition and elected M. Doumergue as M. Millerand's successor instead of M. Painlevé, the candidate of the *cartel des gauches.*

Some months later through a by-election, M. Millerand was elected Senator for the department of the Seine. He then became president of a group formed to denounce the policy of the *cartel des gauches* throughout the country. His success as an orator was apparent both in the courts and in Parliament. (P. B.)

MILLET, FRANCIS DAVIS (1846–1912), American painter *see* 18.466), was drowned in the "Titanic" disaster April 15 912.

MILLIKAN, ROBERT ANDREWS (1868–), American hysicist, was born at Morrison, Ill., March 22 1868, and re- eived his education at Oberlin College (A.B., 1891; A.M., 1893) vhere he was instructor in physics 1891–3. He then proceeded o Columbia University (Ph.D., 1895), and the universities of 3erlin and Göttingen (1895–6). In 1896 he was appointed assist- nt in physics at the University of Chicago, with which institu- ion he continued to be associated for the next 25 years in the lepartment of physics, being professor from 1910 to 1921. In 921 he became director of the Norman Bridge laboratory of hysics and chairman of the executive council of the California nstitute of Technology at Pasadena, California. He was vice- hairman of the National Research Council, Washington, D.C., 1 1917, and chief of the science and research division of the ignal Corps, U.S.A., with the rank of lieutenant-colonel. In 922 he was the first exchange lecturer to Belgium on the .R.B. Foundation.

The best known of his researches were the "oil drop" experi- nents, undertaken with the view of making measurements of ndamental electrical quantity. They proved conclusively at all electrons are alike. He also undertook researches into hotoelectric effect. Later research of his has tended definitely to ridge the gap between light and X-ray phenomena. He was warded the Nobel Prize in physics in 1923 for his work in olating and measuring the electron, and in making the first xact photoelectric determination of the light-quant. In the me year he received the Edison Medal for especially meritorious ork in the field of electricity, and the Hughes Medal of the oyal Society in recognition of his determination of the elec- onic charge and other physical constants. (*See* PHYSICS.)

Millikan was the author of the following, among other works:— *echanics, Molecular Physics and Heat* (1901); *Electricity, Sound d Light* (1908); *The Electron* (1917); *Practical Physics* (1920); *cience and Life* (1923); in addition to numerous contributions to chnical periodicals.

MILLS, ROGER QUARLES (1832–1911), American legislator *ee* 18.475), died at Corsicana, Tex., Sept. 2 1911.

MILNE, SIR GEORGE FREDERICK (1866–), British gen- al, was born Nov. 5 1866 and joined the Royal Artillery in 85. He served in the Nile Expedition of 1898, and the South frican War (1899–1902). In 1913 he became commander of e artillery of the 4th Div., with which he went out to France 1914. He was given, in July 1915, command of the 27th Div., hich, three months later, he took out to the Salonika theatre. t the end of the year he was placed in charge of an army corps ere. In May 1916 Milne was advanced to the command of e British forces in Macedonia, and he occupied this responsible sition under the orders of three successive French commanders- -chief until the end of the struggle. During the ensuing two ears, the situation scarcely lent itself to effectual offensive opera- ons, and the British military authorities at home were opposed the using-up of resources in this theatre. Milne, however, led a difficult position with unfailing tact and sound judgment, d, when a general advance at last took place in the autumn 1918, after Bulgarian powers of resistance had waned, the rces under his personal command contributed appreciably to e bringing about of the final victory. He remained in charge the British forces in the Near East and about the Black Sea til 1920, and on return to England was appointed to the East- n command. In Feb. 1926 he succeeded Lord Cavan as Chief the Imperial General Staff. Possessed of exceptional strength character and decision, an eye so keen in its perception of eaknesses as to be proverbial in the army, these qualities were ended with a sympathetic understanding of men and a marked nse of humour. Even more significant, for an era of military ansition, was his known receptiveness to new ideas.

MILNER, ALFRED MILNER, VISCOUNT (1854–1925), British atesman (*see* 18.476), occupied himself mainly, after his return om South Africa, with business interests in the City of London. But, though he took up a somewhat detached attitude with regard to ordinary domestic politics, he was active on behalf of causes which appealed to him from the imperial side; and he made several speeches in different parts of the country in the next few years on behalf of Tariff Reform and Colonial Preference. He paid a visit to Canada, where he himself and his gospel of imperialism were well received. He was roused, however, by Mr. Lloyd George's budget of 1909, and he advised the House of Lords to reject the Finance Bill, and, as he said at Glasgow, to "damn the consequences." He made several speeches in the next 12 months in defence of the Lords' position; and when the Parliament Bill came up to the House of Lords in 1911, he was a leading spirit among the "Diehards" who advised resistance to the end. He did not take a very prominent part in the opposition to the Irish Home Rule Bill; but he aptly described the state of affairs in Ireland in the early summer of 1914 as "smouldering war," and he urged the remodelling of the Amending Bill so as to reassure the Ulstermen.

The World War confirmed all his fears as to the disadvantages under which Great Britain and the Empire would labour during hostilities through the practice of unlimited Free Trade by the mother-country for over half a century. He gladly accepted in the summer of 1915 the chairmanship of a committee of technical experts and practical agriculturists, appointed by Lord Selborne as President of the Board of Agriculture, to consider the means of maintaining and increasing food production in England and Wales. The committee reported that farmers should be encouraged to grow more wheat by a guaranteed minimum of 45 s. a quarter for the four years following the harvest of 1916. Mr. Asquith's Coalition Govt. did not think the situation serious enough for this drastic remedy. Lord Milner became critical of this "wait and see" attitude; and especially reprobated on several occasions the policy of concealing disagreeable facts. "Truth all round," he said at Canterbury on Oct. 30 1915, "is the most fortifying thing in the world;" Englishmen could not brace their nerves and steel their hearts to win through by emulating the ostrich. Similarly he did his utmost, in April 1916, to induce doubting ministers to accept the policy, which the country demanded, of universal compulsory service, as absolutely necessary under the circumstances.

Mr. Lloyd George, when he formed his ministry in the following Dec., at once turned to this resolute statesman, the only British administrator who before 1914 had directed a war from the civil side, and constituted him one of his principal colleagues in his War Cabinet of four (or five including Mr. Bonar Law). Considering the attitude of the two men at the time of the South African war, the offer and acceptance argued magnanimity on both sides. From this time to the cessation of hostilities their relations were close, and, after Mr. Lloyd George, Lord Milner took the largest share in the civilian conduct of the War. In vigour, resolution and readiness to take responsibility they resembled each other; but Lord Milner's experience, scholarship, steadiness and somewhat bureaucratic habit of mind supplied an invaluable complement to his chief's daring, impatience of precedent, quickness of apprehension and intellectual agility. In Feb. 1917 he attended, on behalf of the British Govt., a conference of the Allies in St. Petersburg (Leningrad), the object of which was to improve the co-ordination in the prosecution of the War between the Government of the Tsar (then in its last weeks of existence) and the Western Powers.

He devoted himself to his duties in the War Cabinet, never making speeches in the country, and seldom in the House of Lords, where his appearances were mostly in explanation of the policy of the Government in regard to food production and control. In June 1917 he announced that ministers had added between 70,000 and 80,000 men to the people available for agricultural work. In Feb. 1918 he vigorously defended Lord Rhondda's administration at the Food Ministry against ignorant criticism, and said that in regard to food Britain was in a better position than any other country except the United States. Except for what was necessary for the conduct of the War, everything must give way to food supply. The corn production bill of 1917, and the acceptance by the Government of the principle of Imperial Preference, and of the conservation of the raw materials of the Empire, owed much to his influence and support. He worked heartily for inter-Allied co-operation in the conduct of the War, and with Mr. Lloyd George attended meetings of the Supreme War Council at Versailles. He was in France as the representative of the British Cabinet at the time of the victorious German advance in the last 10 days of March 1918; and it was largely owing to his influence that Gen. Foch was appointed at Doullens on March 26 Generalissimo of the Allied forces in France. It being vital to have a man of unusual capacity and vigour at the War Office in this critical spring of 1918, Lord Milner was given the seals of Secretary of State for War on April 19; and it was he who presided over the Army Council during the succeeding months of the year which ended with victory.

In the reconstruction of the Ministry after the general election, Lord Milner left the War Office and became Colonial Secretary, a position for which his lifelong interest in the Empire peculiarly qualified him. In that capacity he attended the Paris Peace Conference as one of the British plenipotentiaries, and was a signatory to the Treaty of Versailles; and he subsequently helped to deal with a number of difficult questions arising under the treaty out of the disposal of the German colonies conquered in war. But his colleagues utilised his services also in other directions. His financial authority was invoked to defend ministerial finance in the House of Lords; and when a serious revolutionary outbreak took place in Egypt in 1919, he was sent there, as the author of *England in Egypt* (1892), at the head of a special mission to inquire into the causes, and to report on the form of constitution best calculated to promote Egyptian peace and prosperity. The mission arrived at Cairo in Dec. and remained till March; then in the summer of 1920 Lord Milner and his colleagues had long conferences with Zaghlul Pasha, the leader of the Nationalists, in London; and ultimately in Nov. they issued a memorandum recommending the recognition of Egyptian independence. Great Britain was to guarantee the integrity of Egypt against aggression; she would have a privileged position in Egypt and would maintain a garrison in the canal zone. The capitulations were to be abolished, and the veto on legislation affecting foreigners would be vested in the High Commissioner. The new constitution, of which these were to be the principal features, had not yet been adopted when Lord Milner, who had only accepted office because of the national need, resigned in Feb. 1921, and his great services were fittingly recognised by the Order of the Garter. Before the end of the month he married Lady Edward Cecil, the widow of Lord Edward Cecil, formerly Miss Violet Maxse.

Lord Milner returned to his business interests in the city, and during the remaining four years of his life, though he took an active part in the work of the Rhodes Trust, and also published his views (*Questions of the Hour*, 1923), he only once showed any disposition to resume public work. When Mr. Baldwin, in the autumn of 1923, boldly appealed to the country for a mandate to introduce Protection, Lord Milner accepted the chairmanship of a committee to advise the Government as to the proposed tariff. As the electorate rejected Protection, the committee proved abortive. In the winter of 1924–5 Lord and Lady Milner paid a private visit to South Africa, where he renewed old friendships and received a warm welcome from those who appreciated the great services which he had rendered to that country. Shortly after his return he was attacked by sleeping sickness and died on May 13 1925 at his residence Sturry Court, near Canterbury. His death coincided with his unopposed election to the chancellorship of his old university, Oxford; and funeral services in Canterbury Cathedral and Westminster Abbey gave expression to the public sorrow and respect. There was found among his papers, and published shortly after his death, an impressive document containing his *Credo* (1925). (G. E. B.)

MILOVANOVIĆ, MILOVAN (1863–1912), Serbian statesman and diplomatist, was born at Belgrade on March 2 1863, and was educated there and in Paris, where he was the first Serb to take his degree as doctor of law and was awarded a gold medal for his
thesis. On returning home he was appointed professor of inte
national law at Belgrade University and soon acquired the po
tion of one of Serbia's leading jurists. He was mainly responsib
for drafting the new Serbian constitution of 1888; and, becomin
secretary of the central committee of the Radical party, he e
tered politics and held successively the portfolios of Justic
Commerce and Finance during the closing decade of last centur
In 1901 he went to Rome as minister, and retained his post aft
the revolution of 1903. In 1907 he represented Serbia at t
Second Hague Conference, and was appointed a member of t
international court of arbitration. In July 1908 he was ma
Foreign Minister in the Vetimirović Cabinet, and thus had
guide Serbian policy through the difficult period of the Bosni
annexation crisis.

In 1911 he succeeded Păsić as Premier, and, being less of a pa
ty man than his old Radical colleagues, was able to bridge man
gaps, and to acquire within a short space of time a unique pos
tion among the politicians of Serbia. Even in foreign politics
showed signal moderation, and though a confirmed Russophi
initiated negotiations for a commercial treaty with Austria-Hu
gary and actively favoured good relations with Turkey. He w
one of the chief founders of the Balkan League, the decisive st
towards the creation of which was taken at a meeting betwee
Milovanović and the Bulgarian Premier, Gueschov, on Oct.
1911. Secret negotiations continued throughout the winter an
led to the conclusion of the Serbo-Bulgarian Treaty of March
1912 (*see* SERBIA). Discussions were still pending between th
various Balkan capitals for a more precise and comprehensiv
project of alliance when, on July 1 1912 at Belgrade, Dr. Mil
vanović died suddenly of heart failure. His removal at so critic
a juncture was a grave blow to the cause of peace and moderatio
and also deprived Serbia of her ablest statesman since the deat
of Prince Michael.

MILWAUKEE, Wis., U.S.A. (*see* 18.492), had a population i
1920 of 457,147 (100 males to 100 females); in 1925 the censu
bureau estimate was 509,192. If suburbs within 10 m. are in
cluded the total for the metropolitan district is over 600,00
Between 1910 and 1920 the number of negroes, though sti
comparatively small (2,229), increased 127%; the number o
foreign-born decreased slightly, to 110,068, of whom 39,771 wer
born in Germany and 23,060 in Poland. Natives of German
constituted only 8·7% of the total population in 1920, as com
pared with 18·9% in 1900.

The assessed valuation of all taxable property in the city ha
risen to $810,509,504 in 1925, more than four times the figure
years earlier. Adding to this the value of property exempt fro
taxation (about $144,000,000) and of public utilities assessed b
the Wisconsin Tax Commission (about $102,000,000), a tota
value for all real estate and assessable personal property of ove
1,000 million dollars was indicated. Ranking 13th in populatio
among the cities of the United States in 1920, Milwaukee ranke
12th in the value of its manufactured products in 1919 and 11t
in 1923 ($576,161,000 and $514,591,065 respectively, compare
with $208,324,000 in 1909), leading all others in the productio
of cranes and hoists, large shovels, excavators and dredges
steam and water turbines, large hydraulic electric units, roc
and ore crushers and many other kinds of machinery, sil
stockings, wheelbarrows and work-shoes. Progress in cit
planning included the preparation of a comprehensive pla
(1917), the enactment of zoning ordinances (1920 and 1924), and
the acquisition by the city of the greater part of the lake front
and of land for a civic centre.

Effect of Prohibition.—The large brewing industry was dissipated by national prohibitory legislation. Some of the companies used part of their plant for manufacturing "near beer," ginger ale and other "soft" drinks, or leased part of it for other industrial purposes, but a large part of the investment in the breweries was still lying idle in 1926.

MILYUKOV, PAUL NIKOLAYEVICH (1859–), Russian politician and historian, was born near St. Petersburg (Leningrad) Jan. 27 1859. He studied history and humanities at the University of Moscow, and received the degree of master in story for a learned work on the *State Economics of Russia in e First Quarter of the 18th Century.* His liberal opinions brought m into conflict with the educational authorities, and he was smissed in 1895 after one of the ever-recurrent university riots." After the meetings of the Zemstvos in 1905 he became e political editor of an important liberal paper, the *Retch*, d took an active part in the formation of the Constitutional emocratic party (Cadets). Milyukov became the leader of at party, although he was not elected a member of the first the second Duma. When the Tsar dissolved the first Duma was one of the principal prompters of the "Viborg mani- to," in which the members of the assembly declared them- ves ready to follow the people in resisting arbitrary rule. ilyukov did not sign, however, as he was not a member of the ıma, and escaped the persecution which accompanied the olypin reaction. He was elected to the third and the fourth ıma, and played the part of a leader of the opposition, system- cally criticising the policy of the Government.

When the World War broke out he stood for a policy of tional union and active co-operation with the Entente, but e corruption of the War Office drove him into an attitude of reasing hostility. Milyukov took office in Prince Lvov's ovisional government as minister of foreign affairs. Later he ongly disapproved of Kerensky's policy, and when the lsheviks seized power he escaped to Kiev then occupied by the rmans and gave up the cause of the Allies as lost. After Armistice Milyukov went to London and subsequently to ris, where in 1921 he directed a journal (*Last News*) in which advocated an alliance with patriotic Socialists.

MIMICRY: *see* COLOURS OF ANIMALS.

MINELAYING AND MINESWEEPING.—Explosive contrivan- were moored and used against ships, as early as 1800. It was , however, until the American Civil War that the sea mine ame an accepted weapon of naval warfare; nor did it prove a ent danger to the capital ship until it played an all-important t in the siege of Port Arthur some 40 years later.

I. MINELAYING

mongst the decisions of international conferences at The gue it was agreed, and ratified by the Great Powers (other n Russia), that mining in war should be limited to operations hin territorial waters. The unfortunate result of this was to the British Admiralty into a false sense of security, and the ing service thus became a side issue. The German Carbonit e, used by the Germans throughout the World War had n originally offered to the British Admiralty. It was refused the plea of expense; and, in its place a mine of about one- rter the cost was manufactured and supplied to the naval ice. The Hague agreement was torn to pieces within a few rs of the outbreak of the World War, and as the War pro- sed the necessity for constant minelaying became evident.

lements of Mining Warfare.—Three factors are necessary successful mining warfare—the strategic function, the opera- of laying the mines and the technical efficiency of the mine f. The first of these factors is woven into the main strategy naval war. The stronger fleet, in its anxiety to seek out and roy its enemy, desires a clear sea; and, to obtain this, must re that such a means of attrition as the mine is reduced to utmost. On the other hand, the weaker fleet will use the mine usely in an endeavour, by attrition, to reach an equality of e: and it will also use this weapon against merchant ships, icularly when they belong to a belligerent dependent on its iage of foodstuff from overseas. This was the initial stage of l strategy in the World War; and to some extent it explains pre-War application of the Germans to mining. The second or is the operation of laying the mines. To be successful, this t be governed by the element of surprise, and be expeditiously ormed; it requires for its purpose a ship of exceptional speed, ne which, by disguise or subterfuge, can carry out the work olested. The value of merchant ships for minelaying was gnised, and the Germans had such ships ready at the reak of war and speedily augmented the number of them.

The third factor is purely one of technique. No type of mine that does not meet the following requirements is efficient. It must be safe until it is laid. When laid, it must take up and maintain its required depth, throughout all kinds of weather, for an appreciable length of time. It must be immune from mechanical failure when required to function. In the interest of all belligerents, it must automatically render itself safe should it break from its moorings. Mines that fail in any of these respects may become a greater danger to friend than to foe. The German Carbonit mine answered these tests except in the last requirement. The early British mine was unfortunately only fully efficient in the last requirement. Considerable importance attaches to the design of a minefield. A simple straight line of mines is easily and quickly laid, but presents little difficulty to the minesweepers once it is located. Lines of mines laid in zigzags, particularly when spaces of water are left clear, present the greatest difficulty to removal. On the other hand, such patterns will necessarily cover a larger sheet of water, and will require very accurate plotting, if subsequently the vicinity of the mined area is to be approached by the sea forces of the minelayer. An existing apparatus termed "taut wire gear" proved a great aid to accuracy in positioning a minefield.

German Practice.—German submarine minelayers usually confined their mines within an area of two or three sq. miles, laying them in groups of four, or even less. The position chosen was most frequently near some focal point, buoy or lightship, or at the entrance to a naval base or commercial port. For instance, during the War, over 450 mines were laid by German submarines within a mile of the Shipwash Light vessel, a position necessarily passed by all traffic up and down the east coast war channel, by the convoys to and from Holland and by Com. Tyrwhitt's destroyer flotillas whenever they left or returned to their base at Harwich. The Germans also allotted to each of these submarines a particular stretch of the British coast. The flotillas working from Flanders covered the coast from Flamborough Head south about to the Clyde, also the northern French coast; the high sea, or large boats, working from the Elbe, were responsible for the rest of the English and Scotch coasts, and the whole of Ireland. Each commander being restricted to work in his individual area, the danger of striking previously laid mines was minimised. The commanders, moreover, by this arrangement, got quickly into touch with the local movements of the traffic, the method and capacity of their opposing minesweepers and the coastal navigation within their beats. In most cases after some 10 to 14 days a commander would not hesitate to pass over a position where he had previously laid mines. He would be confident that his mines had been discovered and cleared if shipping had been seen in the area.

Moored mines could be laid in any depth up to 100 fathoms, or even more in tideless waters, and they could be regulated to lie at any depth below the surface. Deep mines were used against submerged submarines, and shallow ones against surface shipping. In a strong tide, with a long mooring-rope, the mine will bend over to the tide; so that the mines, under strong tidal conditions, always lay too deep to be harmful to surface ships. In a position such as the Pentland Firth, mines were in fact only a danger at slack water, a period of minutes only. Again, the difference in height between high and low water was an important matter. If, for instance, the tidal range was exceptionally large, as in the Bristol Channel or Bay of Fundy, all types of ships could pass over a minefield at high water in perfect safety, provided no mines had been seen at low water on the surface.

British Minelaying Resources.—At the outbreak of hostilities in 1914 the British Navy possessed seven old cruisers (Latona class) fitted as minelayers. These had a speed of only 14 knots. Shortly afterwards four merchant ships were added; and in the second part of the War a considerable number of submarine minelayers and fast destroyers were used. On Oct. 2 1914 the first line of 1,264 mines was laid by the old cruisers in an area 10 m. north of Ostend. This had the effect of forcing neutral shipping to pass through the Downs. Unfortunately, the British mines then in use proved so defective that for a time minelaying had to cease; and although in 1915, after some technical improvement, some 15 more minefields were laid, it was not until 1916 that attention was concentrated on providing a mine of the calibre of that used by the Germans.

British Activities from 1916 Onwards.—One of the principal British minelaying operations of 1916 was a coast barrage, consisting of a double line of deep mines, running for 40 m. from the Belgian coast, at a distance of 12 m. from the shore. It was supplemented by mine nets laid by the Dover drifters. The work took five weeks to complete; but only one submarine seems to have been accounted for by it. The end of the year saw the institution of a mining school at Portsmouth for research and development.

On the assumption that the Belgian coast barrage had been effective, a similar barrage was completed in Feb. 1917 across the Straits of Dover; but the mines dragged and had to be swept up. It was, however, relaid by the end of July 1917. In Jan. 1917 it became essential to encircle the Heligoland Bight and thus to surround all exits from German ports; but the shortage of mines at the time caused the operation to be postponed, nor was the British mine considered suitable for it. However, towards the end of 1917 the "Abdiel" and five minelaying submarines had laid nearly 16,000 mines in the German Bight; and these accounted for a certain number of German destroyers and minesweepers. The mine used in the later stages of this operation was the new British H2, which, except for its method of taking depth, was similar in principle to the German Carbonit mine.

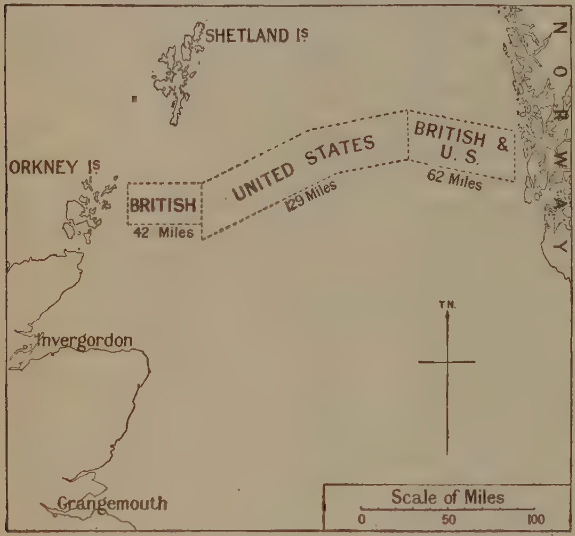

Fig. 1.—Plan of the great northern mine barrage, consisting of 63,117 mines. Laid in 1918 by British and U.S. submarines.

The German method of depth-taking was for the mine, attached to the sinker, to drop to the bottom, where, after a short interval for the purpose of safety, the mine released itself from the sinker and rose to the depth for which it was set. In the British method the mine did not go to the bottom; it did not, in fact, go below the depth for which it was set. The sinker regulated the depth while the mine was still on the surface; then, in sinking, pulled the mine down to its required position. An advantage of the British system was that heavy water pressure on the mine-case was obviated; but, on the other hand, it did not obtain the exceptional accuracy in depth-taking which was noticeable in the German method. In due course the new H2 mine was delivered in sufficient quantity for the long-delayed defensive minefields to be begun by the British, and an extensive new barrage in the English Channel was then completed. Between Folkestone and Cape Gris Nez 9,500 mines were laid in 20 parallel lines, the shoals of the Varne and the Ridge dividing the area into three sections. This barrage effectively closed the Channel exit to the German submarines, nine of which were l in attempts to pass it.

Minelaying by the United States.—The entry of the Uni States into the War admitted of a large augmentation in mi and in minelayers; and an attempt was made to close the nor ern exit from the North Sea by a mine barrage between the O neys and the Norwegian coast (see fig. 1). This operation undertaken by both British and U.S. minelayers. The lat formed a base at Inverness, and supplied ten large minelay with a total carrying capacity of over 5,500 mines. The Uni States used a mine of a novel type. It carried the usual cha of 300 lb. of tri-nitro-toluene, but from each mine there exten antennae for a distance of 35 ft. which, if touched by a me ship, exploded the mine. The result was that the danger z was largely increased.

The vast area covered by mines can best be appreciated b reference to the plan, which gives an idea of the work carr out by the U.S. minelayers. Difficulties were encountered the operation proceeded. A proportion of the American mi exploded prematurely; while a number of British mines took a shallower depth than intended, and had to be swept up a relaid. The complete operation, however, was finished by Ju 1918. It must not be supposed that the whole water availa for a submarine was effectively covered by this minefield; the dangerous area was greatly increased and an effect on morale of the Germans quickly produced. In July German s marines began to creep past in Norwegian waters; but the N wegians closed this coastal lane to both belligerents by mi fields of their own. Of the mines laid in the Northern Barr 56,571 were American and 13,546 British. All this time encircling of the Bight had been going steadily on, and some 000 mines were in place by the date of the Armistice. During period of the War, approximately 160,000 mines were dropp in the North Sea and Channel by the British and Ameri minelayers, the very great majority of which were laid dur the last 18 months of the War.

II. MINESWEEPING

Before the outbreak of War in 1914 the British Navy had, some extent, realised the possibility of a mining offensive on part of their enemies; and, largely due to the foresight of late Admiral Lord Charles Beresford, trawlers had been tes and had proved efficient minesweepers as early as 1907. A traw reserve purely for minesweeping was instituted shortly aft wards. Thus, by Aug. 8 1914, 96 hired trawlers had put to sea sweep up enemy mines, and within a fortnight another 100 tra ers had been requisitioned and were fitting out. The traw minesweeper, however, did not entirely cover the requiremen as it was too slow to sweep the water ahead of a moving fle and this had been realised, and to some slight extent, cate for, by training a flotilla of eight old torpedo-gunboats. Th ships were capable of towing the sweep at 12 knots, which double the speed at which the majority of the trawlers co operate. This gunboat flotilla moved north from Dover on J 31 1914, and, with sweeps out, actually covered the track o which the Grand Fleet passed. They were necessarily mu overworked in the first six months of the War, as, whene practicable, they swept the waters through which the fl moved, and were also constantly required to search areas wh mines were expected to be laid. Fortunately no mines were l near the bases of the fleet until much later, when this sm flotilla had been considerably augmented.

Methods of Sweeping.—At the outbreak of War, the Brit system of minesweeping was for two vessels to tow a stout w between them, the wire being kept at the required depth means of water-kites. The towed wire, termed the sweep, th came into violent contact with the mooring-rope of a mi which it generally broke, causing the mine to come to the su face, when it could be sunk by rifle-fire. In some cases, howe the sweep would strike a horn of the mine, and explode it. Th occasionally led to the parting of the sweep and consequent del while a new wire was passed. The most serious drawback w if the sweep failed to break the mine wire, when the mine would be towed along, more often than not unknown to the sweepers. This latter trouble caused many of the early minefields to be scattered far beyond the limits in which they were laid, and constituted a serious danger. The eventual safeguard was to heave the sweep slowly in, and to sight the whole wire and water-kites on the surface before slipping it, when a mine holding to the wire would be seen and reswept afterwards. The innovation of a serrated form of sweep wire eventually reduced the difficulty to a considerable extent. This simple method of minesweeping stood the test of the whole War, and its simplicity had the great advantage of reducing the training period which would have been necessary had a more complicated apparatus been used.

The French towed from a single vessel two sweeps, one on either side, each kept out by an otter similar to the usual otter used in trawling, but regulated for depth by attachment to a large torpedo-shaped float, the depth at the other end being regulated by a water-kite. Along each wire was distributed a series of small mechanical and explosive wire-cutters. The "shooting" of these sweeps caused trouble unless the crews were adept, and the speed at which the apparatus could be towed was limited to six to seven knots. The spread of the British system was 400 to 500 yd. per pair according to the type of minesweeper, that of the French system not more than 200 yards. In the latter part of the War the Americans adopted the French method, which had by then been somewhat simplified.

The German system was akin to the British, excepting that, in order to cover the route of their fleet more quickly, they instituted a very light form of sweep which could be towed at 20 knots. Directly this apparatus met with an obstacle it was automatically slipped, thus giving notice of the obstruction, whereupon the slower type of sweepers were hastened to the spot to clear it. In practice this system constantly led the fast sweepers to report mines when they had only encountered wrecks or some other harmless obstruction, and little confidence was therefore placed in the reports of mines by this fast flotilla.

Under ordinary cruising conditions, searches by sweepers were made whereby only a small percentage of the water was covered—sufficient, however, to allow a strong probability of the presence of mines being discovered in good time. The introduction of the "paravane," which protected the ship herself, very much reduced the mine danger; but men-of-war were not fitted with this device until 1917, nor by the end of the War was it general in merchant ships. The paravane is an apparatus which, for assured efficiency, requires skilled handling. There are situations where its use is impracticable, and it has not replaced the necessity for the minesweeper.

Early Difficulties.—The War was only a day old when the first mining operation was undertaken by the Germans. An armed merchant ship, the "Königin Louise," laid a large minefield off Southwold, at a distance well outside British territorial waters. The "Königin Louise" was sunk, but H.M.S. "Amphion" struck a mine after the action. This minefield caused considerable loss to merchant ships, many of which were neutrals. It also led to early losses of minesweeping trawlers, in which the mortality was heavy. Throughout the War, an average of half of the crew of a trawler was lost when one was mined. For the first two months of the War, for every two mines swept one trawler was lost. Improved method and greater experience later minimised the losses, until an average of one loss for every 80 mines was achieved in 1918; but the effect on shipping in the early days was such that any form of flotsam was reported as a mine.

The outcry for minesweepers became universal, and more trawlers were requisitioned. In Great Britain there was no lack of volunteers from the fishermen, nor of officers from the Naval and Naval Volunteer Reserves; but all of these were untrained in minesweeping, efficiency in which was proving so essential. By Sept. 1 1914 little had been done with the Southwold-Aldeburgh minefield, other minefields were suspected, insurance rates were rising, and the situation had become grave. A rear-admiral was appointed as Admiral of Minesweeping on the East Coast. The immediate situation was dealt with by the institution of a channel close to the coast, buoyed adequately and swept continuously. Merchant shipping was instructed to pass close to the line of buoys; but the organisation requisite to insure this information reaching all the ships, and the difficulties of enforcing obedience, were not overcome for a considerable time. The losses were reduced to a slight extent, however; and when this channel was extended from Dover to the Firth of Forth, and the organisation was perfected, losses by mine were the exception. Against the British Fleet no mines were laid during the first year of War; but the situation in mined localities had emphasised the necessity for a larger Fleet Sweeping Flotilla, and a number of special vessels, termed sloops, were laid down.

Details of Minefields.—The actual minefields laid by the Germans between Aug. 5 1914 and Aug. 5 1915 were as follows:—

1914	Aug. 5	Aldeburgh-Southwold	180 mines
1914	Aug. 26	off Humber	200 mines
		Tyne	194 mines
1914	Oct. 26	Tory I. (Ireland)	200 mines
1914	Nov. 3	Smith's Knoll	130 mines
1914	Dec. 16	Scarborough	100 mines
1915	April 4	Swarte and Indefatigable Banks	360 mines
1915	May 16	E. Dogger Banks	480 mines

These mines were all laid by surface vessels, and accounted for a heavy toll in merchant vessels and minesweepers.

At the entrance to the Dardanelles minesweeping had to be carried out under heavy shellfire. At first only slow trawlers were available, and night clearing was never a practicable operation.

Growth of the British Minesweeping Force.—In British home waters the augmentation of the minesweeping force was less difficult than abroad. Light-draft excursion (paddlers) were requisitioned in addition to the newly built craft already mentioned, and by April 1915, over 150 vessels purely for minesweeping were distributed as follows: Grand Fleet—6 gunboats, one new sloop and 10 trawlers. Scotland—47 trawlers. Humber—6 paddlers, 30 trawlers. Lowestoft—47 trawlers. Harwich—33 trawlers. Dover—12 trawlers. South Coast—24 trawlers. West Coast—4 trawlers. Clyde—6 paddlers. In the Dardanelles 8 cross-channel steamers had augmented the trawler force, and destroyers had been fitted for minesweeping.

The Submarine Minelayer.—Up to June 1915 all minefields had been laid by surface vessels; but in this month came the first effort of the submarine. A small type, termed U.C. boats, working from Zeebrugge, with Bruges as a mine-depôt, commenced laying batches of 12 mines held in vertical shoots, at first between Dover and Harwich, and later over a wider area. During 1915 54 cargoes (648 mines) were laid in this manner. The effect was a serious increase in British losses by mine, which comprised 5 supply ships, one hospital ship, 2 Trinity House vessels, 34 British steamers, 24 neutrals, 19 fishing boats, and 15 minesweepers, a total of 100 vessels. A useful form of night-sweep came into use against this menace, consisting of a light wire, a depth float kite and explosive grapnel. It was to some extent similar to the German high-speed sweep, and prone to the errors of the latter. No fully efficient minesweep for use in the dark hours was evolved in the War, although this light wire served for searching purposes on several occasions when shipping was forced to arrive at a port at daybreak. In June 1915 the Germans had also extended their minelaying to Archangel, where a unit of six British trawlers was dispatched to assist the Russians. They destroyed 150 mines in this locality under severe conditions of service.

Mining Against the Grand Fleet.—The first mining offensive against the Grand Fleet occurred in Aug. 1915, when 380 mines were laid in the entrance to the Moray Firth, distributed over lines which totalled nearly 70 miles. A large portion of the fleet was at Invergordon at the time. The results were negligible, the losses being confined to minesweepers and one destroyer. A channel was found to be clear on the northern side of the Firth, which was at once used as an exit for the fleet. On the southern side, however, a channel was cleared, but an area of mines was purposely left to form a defensive barrier and so limit the water necessary for patrol and minesweeping. On Jan. 1 1916 the area west of Scapa Flow was mined by the "Moewe" on her passage into the Atlantic. In this field 252 mines were laid, endangering an area of 40 sq. m., which resulted in the loss of H.M.S. "King Edward VII." before the presence of mines was realised. Once located, this area was treated in the same way as the Moray Firth.

Progress in 1916.—By the beginning of 1916, 14 sloops had joined the Grand Fleet, and 35 hired paddlers were in action. The success of this latter type led to 24 being laid down by the Admiralty, and also a new type of twin-screw sweeper, known as the "Hunt" class. The value of these ships lay in their seakeeping qualities and shallow draught. The paravane also passed its test in 1916, and by the end of the year had been supplied to 180 of H.M. ships. Shaped like a torpedo, it contained mechanism for accurate depth keeping at any appreciable speed, and was capable of carrying a heavy wire cutter on the nose, or, when used against a submarine, an explosive charge. As a mine-protection it was towed from a sliding "shoe" which worked up and down the stem of the vessel. The paravane automatically ran out from a ship under way, stretching the wire rigidly at an angle of about 50 degrees to the fore and aft line of the ship. Towed from the point of greatest draught, the wire protected the whole of the ship from a mine; for, on coming in contact with a mine mooring, this wire deflected the mooring until it entered the cutter on the paravane, which instantly functioned. The mine then came to the surface clear of the ship. A modified form of this apparatus was fitted in merchant vessels; and, by the end of the War, 2,740 merchant ships had been fitted. Paravanes in H.M. ships cut 55 mine moorings, but the number cut by merchant ships was less.

The number of German submarine minelayers increased in 1916, and there were larger boats operating over a still wider area. These carried 18 mines. As further construction improved, the number of mines carried rose to 24, and in 1917, to 36. The larger boats worked from the Elbe, and the smaller from Flanders. On May 29 1916, U75 laid her 18 mines close to Marwick Head, off the northwest coast of Orkney. The operation was part of the pre-Jutland submarine actions of the enemy. It is understood that a mining operation on the western exit from Scapa was intended, with a view to crippling the Fleet should it use that exit. The contour of the coast near Marwick and that off the western entrance to Scapa, a few miles to the southward, are very similar, and a mistake in the landmarks was possibly made by the submarine commander. In view of the time elapsing between the laying of the mines and the sailing of H.M.S. "Hampshire" from Scapa Flow for Russia, it would seem obvious that the position chosen is not susceptible of a tactical explanation. Sixteen mines from this batch were swept up directly afterwards in this position, and one was recovered set for a depth of seven metres. (It transpired, after the War, that all these mines were set for this depth.) The tide was appreciable, causing sufficient "mine dip" to insure the mines at this depth being innocuous even to a heavy-draught ship, except at low slack water, and with considerable motion on that ship. The period of slack water was extremely limited. The "Hampshire," proceeding in a sudden gale, and hugging the shore to obtain less sea, struck one of the mines at low-slack water. By this curious conjunction of all these factors, the career of Lord Kitchener was brought to a tragic close. Except for a determined offensive by the Flanders submarines against the Channel Ports, the mine was not extensively used in the latter part of 1916. It would appear that the Germans were then husbanding their resources for unrestricted submarine and mine warfare.

Changes in the British Service.—The reorganisation of the British naval staff in May and June 1917 led to considerable changes in the minesweeping service. The rear-admiral, who had throughout 1916 been very fully employed in concentrating on the paravane and other improvements of minesweeping material, now took over the Dept. of Torpedoes and Mines, which included the technique of minesweeping devices. The control of operations was therefore entirely separated and delegated to a captain on the naval staff, who, in Oct. 1917, became Director of the Minesweeping Div. under the assistant chief of the naval staff. The whole of the minesweeping, then so greatly extending in area, was thus co-ordinated under a central control at the Admiralty.

The intensity of minelaying and expansion of areas in the first half of 1917 was difficult to meet with the minesweepers available; and the climax was reached in April, with a loss of one minesweeper per diem for the greater part of that month. Probably no other service had a more severe strain placed on its personnel during this month and those immediately following. Every available and suitable paddle steamer and motor fishing boat had to be requisitioned; and those incapable of towing a heavy sweep were fitted with a light one, and used for search. Aircraft and motor launches were also used for low-water searches for mines, in order to reduce losses of sweepers; and improvements in traffic organisation and still closer co-operation between adjacent areas were gradually effected. Further protective minefields were laid in certain suitable positions, but the opening of new areas was constantly necessary; and, by the end of 1917, the coastal waters of Great Britain and Ireland, over 1,000 m. in extent, were being swept every day for mines. The war channel was also extended to the Firth of Forth, and merchant ships only released from a night shelter when they could proceed in freshly swept water. One hundred new vessels of the "Hunt" class were laid down, and 300 new drifters put out to contract, so as gradually to replace and release trawlers for patrol and anti-submarine work.

Synchronous mining of adjacent British ports was resorted to by the Germans, which raised many sudden problems in traffic control. The convoy system had now been introduced, and the sweeping of convoys into certain ports often became essential. Particular difficulties arose in regard to Liverpool owing to the shallowness of the channel and narrow entrance; mines swept up, and sunk without exploding, causing serious danger to heavy draught ships by their proximity to the ship when resting on the bottom.

The south coast of Ireland was seriously and continuously mined, and even the bays on the west coast of Ireland did not escape. The year closed with a total of 3,989 German moored mines swept up in home waters, at a cost of 170 Allied and neutral merchant ships sunk and 28 damaged. This total of mines for the year exceeded the combined totals for the previous years of the War. Nevertheless, the outlook was more hopeful. Although the intensity of minelaying had become so much greater, the losses had only been increased by nine ships over those of the previous year: and progressive success in the destruction of submarines and their personnel made it evident that the same intensity and efficiency of the minelayers could not be continued much longer. New construction and greatly improved material for minesweeping had already made their mark. The only fear was that the minesweep would be defeated by some innovation of the enemy. This fear, however, never materialised; although a delayed action (intentional or otherwise) for releasing the mine from its sinker some hours after it was laid was observed on several occasions.

While minelaying had, in home and Mediterranean waters, now been confined to submarines, the "Wolf," a surface raider with 458 mines, succeeded in breaking through the patrols into the Atlantic. Her voyage lasted 15 months. Rounding the Cape of Good Hope, she cruised in the Indian Ocean, then proceeded south of Australia to New Zealand and Fiji; and returning by New Guinea, the Dutch East Indies and the Cape, she reached the Cattegat again in safety. Her mines were distributed all over the globe; and, although the losses caused by them were comparatively light, it was very difficult to obtain suitable sweepers in the various areas to locate and destroy them. It was, in fact, not until the Armistice that all the localities were defined.

End of the Mining Offensive.—The beginning of 1918 saw the defeat of the great mining offensive completed; and by the end of hostilities no more than a dozen efficient German minelaying submarines existed. Their losses had by then completely outstripped new construction, and a well-trained or experienced personnel was entirely lacking. Of the many factors which, taken together, finally killed the minelayer, the most important were: (1) the great efficiency of relaid Dover barrage; (2) the deep minefields in localities regularly used by minelayers; (3) improvements in anti-submarine methods of hunting; (4) co-operation between the Intelligence and Minesweeping divisions; and (5) the distribution of information. In 1918 the average time elapsing from the receipt of the news of a new minefield to its distribution to every base, and to all vessels within the area of wireless communication, was 75 minutes. As a result of these improvements, the total losses by mine during 1918 in home waters were reduced to an average of just two over Allied or neutral merchant ships per month.

Early in 1918, an appreciation of failure led the Germans to concentrate their efforts in minelaying in two directions only. The first was a grandiose scheme, which, commencing in January, was only concluded in late September. It consisted of batches of 36 mines, laid at regular intervals of 10 m, apart on a semicircle 45 from. m the Bell Rock, the result being a complete ring round the entrance to the Firth of Forth. This operation fulfilled a two-fold purpose. It menaced the exit and entry of Norwegian convoys, which were then working from Methil in the Firth of Forth; it also menaced every possible course taken by the Grand Fleet when leaving or entering its base at Rosyth. The scheme, however, was barren of results to the Germans, although methodically carried out in every detail. It was appreciated and countered after the third batch of these mines was discovered, the result being that each of the successive groups of mines was located and cleared immediately; and this was done without the Germans realising that any of these groups had been removed. The other concentration took the form of a field of 400 mines, also laid gradually by submarines. It was directed against the Dutch convoys, and was laid close to the Dutch coast to cover the approaches to the Maas and Ijmuiden. This position was such that any attempts at clearance exposed the minesweepers to a flank attack from enemy vessels. There were some losses by mine, particularly to destroyers escorting the convoys; but the convoys sailed as before, and the losses, on the whole, were very trivial.

Minesweeping after the Armistice.—When the hour of the Armistice struck, a minesweeping force was waiting at the gate of the Dardanelles; and, within 24 hours, 600 British and enemy mines had been removed to clear the way for the fleet to Con-tantinople. For one year after the War, mineclearing was ontinuous in every area where British or German mines had been laid. Under the difficult conditions which immediately ollowed the War, a special minesweeping force had to be en-olled. It consisted of some 600 officers and 15,000 men. Over 13,000 Allied mines and some 70 German mines were cleared rom the sea by British minesweepers. No loss of a merchant hip by mine occurred during that period; and exactly one year o the day from the institution of this force the seas round Britain, her colonies and in the Mediterranean were reported clear. A fine performance in this respect was the clearing by the Ameri-ans of the mines laid between Orkney and the Norwegian coast. The Germans also commenced to clear the heavily mined areas in he Heligoland Bight, and later in the Baltic; but this work of learance was not completed until 1923. Other nations concerned leared their own coastal waters.

MINERALOGY (*see* 18.509).—During the war period of 1914–8 nuch attention was given in all countries to the development f home resources of various minerals of economic value, and to neet new circumstances new sources of supply were developed. urther, there was an increased demand for certain kinds of ninerals, for example those which yield the rarer metals used n the hardening of steel. Much of the mineralogical literature f the period was therefore of an economic character, and many ecent text-books gave prominence to the practical uses of minerals. Fortunately, however, pure science was not altogether neglected. Many new facts have been recorded, and new methods of investigation have been devised.

X-Ray Examination of Minerals.—The X-ray method of investigating the internal structure of crystals has been applied with much success to the study of minerals (*see* CRYSTALLOGRAPHY). The material for examination has usually been prepared as definitely orientated crystal plates, but it is found that the results can be obtained with a fine powder; *i.e.*, an aggregate of minute crystals or fragments of crystals with all possible orientations. The method can therefore be used for the purpose of distinguishing between the crystalline and the amorphous or colloidal states. Since each crystallised mineral gives a more or less characteristic series of bands on the photographic film, the powder method may also be used for the recognition of the minerals present in intimate mixtures, such as fine-grained rocks, ores, clays and soils.

X-rays have also been employed in a method of spectrum-analysis for detecting the presence of the various chemical elements present in minerals. For example, hafnium has been detected, and the amount approximately estimated, in many zirconium minerals.

Microscopical Examination of Opaque Minerals.—A method for the investigation of opaque minerals borrowed from metallography (*q.v.*), in which polished sections are examined under the microscope in reflected light, has proved to be especially useful for the study of metallic ores. It consequently finds an economic application in the valuation of ore deposits. The several mineral species of which the ore is composed can be distinguished, and their relations to one another determined; *e.g.*, the order of their deposition, and whether they are of primary or secondary origin.[1]

The process of grinding and polishing the sections presents certain difficulties owing to the extreme differences of hardness of the several minerals that may be present. The prepared section is illuminated vertically by means of a right-angle prism placed in the tube of the microscope above the objective. Details of structure can be brought out by etching the section with various chemical reagents. The several characters (colour, hardness, relief) of the minerals, together with their behaviour towards reagents, help in their determination. But in many cases ordinary simple tests made on fragments detached from the polished surface are more reliable. Electrical tests can be made with quite simple apparatus: for example, the electrical conductivity can be determined with a dry cell and voltmeter using needles as terminals on the polished surface. Certain optical determinations can also be made in reflected polarized light.

One result of this study of opaque minerals is to draw attention to the extremely intimate association and intergrowth of many of the ore-minerals; this is well shown in the numerous photo-micrographs published by American workers in economic geology. What to all appearances by ordinary methods is a homogeneous mineral may be found by the new method to be really heterogeneous; and, in fact, several supposed mineral species have been proved to be mixtures, and well-developed crystals have in certain cases been found to contain enclosures of other minerals. The method is thus of use for ascertaining the degree of purity of material collected for exact chemical analysis when the formula of a species is to be established. The long-debated question as to how silver exists in argentiferous galena (lead-ore) has been studied by this method. Galena containing 0·10 to 0·35% of silver shows definite spots of tetrahedrite and argentite, whilst specimens containing more silver show evidence of later addition of proustite or pyrargyrite in the form of veinlets.

Mineral Transformations.—In synthetical mineralogy a large amount of experimental work has been done, especially in the Geophysical Laboratory of the Carnegie Institution at Washington. Many minerals and allied compounds have been prepared artificially in silicate and salt fusions. The conditions necessary for their formation and their ranges of stability—either when alone or when in the presence of other compounds—have been studied in detail. One important result obtained by experimenting over wide ranges of temperature has been to show that practically all compounds known as minerals exist in several polymorphous forms.

---

[1] The technique of the subject (called mineralography or mineragraphy) is dealt with in the text-books: J. Murdoch, *Microscopical Determination of Opaque Minerals* (New York, 1916) and W. M. Davy and C. M. Farnham, *Microscopic Examination of the Ore Minerals* (New York, 1920.)

The work has shown that silica (SiO_2) undergoes a remarkable series of changes in its crystalline structure and physical characters when it is submitted to different degrees of temperature. The changes with increasing temperature are:—

α-quartz (rhombohedral trapezohedral), passing at 575° C. into
β-quartz (hexagonal trapezohedral), passing at 870° C. into
β-tridymite (hexagonal holohedral), passing at 1,470° C. into
β-cristobalite (cubic) melting at 1,625° C.

These transformations are reversible, but with falling temperature they take place very slowly. Molten silica unless cooled very slowly solidifies as a glass. β-tridymite when quickly cooled undergoes a change at 163° C. (β_2-tridymite to β_1-tridymite), and at 117° C. passes over into α-tridymite, which is optically biaxial and probably orthorhombic in crystallisation, being identical with the naturally occurring tridymite. Similarly, β-cristobalite when quickly cooled changes at about 180°–270° C. into α-cristobalite, which is optically biaxial (pseudo-cubic) and identical with the cristobalite occasionally found in volcanic rocks.

Now these and many other similar changes give information as to the conditions of temperature under which various minerals were formed in nature, thus providing a "geological thermometer." For example, the presence of tridymite, or of pseudomorphs of the more stable quartz after tridymite, establishes that the rock in which they occur must have been formed at a temperature between 870° and 1,470° C. The quartz of certain veins and that of granite present differences in structure which indicate that the former was formed below 575° C. and the latter above this temperature. Or again, the presence of orthorhombic copper-glance (β-Cu_2S) as a pseudomorph after cubic α-Cu_2S proves that the ore-deposit in which it occurs was formed at a temperature higher than 91° C.

Chemical Composition.—The chemical composition of many minerals is still imperfectly understood, and even for some quite common species there are doubts as to the correct empirical formulae, especially as to the silicates, a satisfactory classification of which is still wanting. Many attempts have within recent years been made to gain some idea as to the constitution of the silicates; there has been much experimental work and plenty of speculation, but with no very definite results. In certain groups, *e.g.*, the feldspars and the garnets, the composition can be satisfactorily expressed on the assumption of the isomorphous mixing of different chemical molecules. But attempts to extend this principle to all silicates often lead to highly complex hypothetical molecules, the existence of which can only be regarded as doubtful. Alternative suggestions have been put forward, such as the "mass effect" of large molecules and the "solid solution" of certain other substances in the main mass of the crystal. Experiments with silicate fusions show that various substances can be taken up, or dissolved, in certain amounts, giving on solidification apparently homogeneous crystals.

Radioactivity.—The strong radioactivity (*q.v.*) of uranium minerals affords a ready means of recognising these valuable ores in the search for them by prospectors. The mineral may be wrapped up with a photographic plate, which is afterwards developed; but a simpler and quicker test is that with a quite simple (home-made) gold-leaf electroscope. A piece of the mineral to be tested is placed on the cap of the electroscope, which is then charged with electricity, readily developed by rubbing with glass or vulcanite (say the mouthpiece of a tobacco-pipe): if the mineral contains uranium (and consequently radium), the gold leaves will soon come together. It is always well to make a comparative test, timing the rate of collapse, with a piece of ordinary stone.

Determinations of the ratio of the amount of uranium to the amounts of the various products of its decay (radium, helium, lead, etc.) present in various radioactive minerals give (knowing the rate of the decay) some idea of the period of time during which these products have been accumulating. In this way estimates have been made of the age in years of these minerals and even of the age of the earth; but, of course, many unknown factors must have been omitted from such calculations. Lead of radioactive origin, or isotropic lead—the final product of uranium decay—is found to vary slightly in its atomic weight (*q.v.*) according to the uranium mineral from which it is extracted.

To radioactivity is ascribed the well-known "pleochroic haloes"—tiny spots or borders of deeper colour surrounding microscopic inclusions—long ago observed in certain rock-forming minerals (cordierite, andalusite, mica, etc.) when microsections of rock are examined in polarised light. The long and continued emission of X-rays from zircon or other mineral grains has caused a change in colour of the surrounding mineral for distances varying from 0·002 to 0·4 millimetre. A study of these has again given some information as to the age of the minerals In this connection it may be mentioned that much experimental work on the coloration of minerals has been done within recent years by exposing the minerals to the action of radiations of various kinds, including ultra-violet rays, cathode rays, X-rays and the rays emitted by radium salts. For example, some diamonds acquire a green colour and fluorspar becomes blue when placed in contact with radium bromide.

Some New Minerals.—In descriptive mineralogy a considerable number of new minerals have been named, but unfortunately in many cases not completely determined and described A few of the more prominent and well-established of these are:—

Carnotite.—Hydrated vanadate of uranium and potassium $K_2O{\cdot}2UO_3{\cdot}V_2O_5{\cdot}nH_2O$, occurring as a canary-yellow crystalline powder impregnating sandstones over a wide area in western Colorado and the adjoining portions of Utah and New Mexico. In Colorado it has been collected on a large scale for the extraction of vanadium uranium and radium. It has also been found in South Australia and in Pennsylvania; and an allied mineral (tyuyamunite, containing calcium in place of potassium) is known from Tyuya-Muyun in Russian Turkestan.

Germanite.—A sulphide ore mineral containing copper, iron and the rare elements germanium (5–8 %) and gallium ($\frac{1}{2}$–$\frac{3}{4}$ %). As a massive, reddish-grey mineral intermixed with tennantite it is found in some quantity at Tsumeb in South West Africa.

Kasolite.—A hydrated silicate of uranium and lead, $PbO{\cdot}UO_3{\cdot}SiO_2$ H_2O, forming radiating groups of small, ochre-yellow, monoclinic crystals. Together with several other new but imperfectly defined minerals, it occurs as an alteration product of pitchblend at Kasol in Katanga, Belgian Congo.

Lorandite.—Sulpharsenite of thallium, $TlAsS_2$, forming transparent, monoclinic crystals with a carmine-red colour and adamantine lustre. It is found with realgar at Allchar in Macedonia, and is one of the few minerals that contain the rare element thallium as an essential constituent (Tl 59·5 %).

Mullite.—Recent experiments have shown that the only aluminium silicate that can be prepared artificially is the compound $3Al_2O_3{\cdot}2SiO_2$, and not $Al_2O_3{\cdot}SiO_2 = Al_2SiO_5$ (fibrolite) as formerly supposed. The same compound, as minute orthorhombic crystals has been found in slates fused by igneous rocks in the Island of Mull Scotland, and has been named mullite.

Patronite.—Vanadium sulphide, VS_4, forming dark greenish-black compact masses. It occurs abundantly at Minasragra, Cerro de Pasco, Peru, where it is a valuable ore of vanadium. It weather very readily with the production of various highly coloured vanadium compounds; even on material kept in collections there is a slow growth of blue and green efflorescences.

Spencerite.—Hydrated basic zinc phosphate, $Zn_3(PO_4)_2{\cdot}Zn(OH)_2$ $3H_2O$, forming pearly white, scaly cleavage masses and small monoclinic crystals. It has been found in some abundance forming large stalactites in a cavern near Salmo, British Columbia.

Tarbuttite.—Basic zinc phosphate, $Zn_3(PO_4)_2{\cdot}Zn(OH)_2$, forming colourless, or faintly coloured green or red, anorthic crystals, with a perfect cleavage in one direction. It has been found in considerable quantity at the Rhodesia Broken Hill Mine in Northern Rhodesia.

Thortveitite.—Silicate of scandium, yttrium, etc., $(Sc, Y)_2O_3{\cdot}2SiO_2$ occurring as large orthorhombic crystals of prismatic habit in pegmatite in southern Norway and Madagascar. This is the only mineral known to contain the rare element scandium in large amount.

BIBLIOGRAPHY.—Details of descriptive mineralogy are collected in Appendices 1–3 of Dana's *System of Mineralogy* (New York, 1899–1915); and numerical data respecting the constants of minerals are tabulated in the international *Tables annuelles de constantes et données numériques*, 6 vol. (Paris, 1912 etc.). A work of comprehensive character is C. Doelter, *Handbuch der Mineralchemie*, 4 vol (Dresden and Leipzig, 1912 etc.). An advanced textbook on new lines is P. Niggli, *Lehrbuch der Mineralogie* (Berlin, 1924, with two more volumes to follow). A number of elementary textbooks have been published, *e.g.*, G. A. J. Cole, *Outlines of Mineralogy for Geological Students* (London, 1912); A. F. Rogers, *Introduction to the Study of Minerals* (New York, 1912); E. H. Kraus and W. F. Hunt *Mineralogy, an Introduction to the Study of Minerals and Crystals* (New York, 1920); H. Buttgenbach, *Les minéraux et les roches* (Paris and Liége, 1924). A popular book with coloured plates is L. J. Spencer, *The World's Minerals* (London, 1911, 2nd ed., New York 1916). Books of an economic character are H. Ries, *Economic Geology* (5th ed., New York, 1925); T. Crook, *Economic Mineralogy a Practical Guide to the Study of Useful Minerals* (London, 1921) B. Dammer and O. Tietze, *Die nutzbaren Mineralien* (2 vol., Stuttgart, 1913–4). *Special Reports on the Mineral Resources of Great Britain* have been issued by the Geological Survey, London, since

1915; and a long series of pamphlets, *The Mineral Industry of the British Empire and Foreign Countries* by the Imperial Mineral Resources Bureau, London, since 1920. New journals are *Fortschritte der Mineralogie, Kristallographie und Petrographie*, issued by the German Mineralogical Society, Jena, since 1911; *Beiträge zur Kristallographie und Mineralogie*, ed. by V. Goldschmidt (Heidelberg, since 1914); *Schweizerische Mineralogische und Petrographische Mitteilungen*, Zürich, since 1921. A review of the recent scientific literature is given in the Mineralogical Society's series of *Mineralogical Abstracts*.

(L. J. S.)

MINERS' PHTHISIS (*see* 18.541b).—Almost any dust inhaled in sufficient quantity may cause chest trouble of some kind or another, but certain dusts are related to the occupational disease variously known as miners' phthisis, pneumonokoniosis, grinders' rot, potters' rot, stonecutters' rot, etc.

Phthisis-producing Dusts.—Dusts with this association are often referred to as phthisis-producing dusts because pulmonary tuberculosis plays a more or less important part in this disease and is always associated with a fatal termination and usually with disablement. Prof. E. L. Collis has shown that the phthisis-producing dust of far the greatest importance in industry is dust of free silica (SiO_2) and the disease is often known as "Silicosis." For a dust to be phthisis-producing it must be comparatively nsoluble and inert and the particles must be minute, say from ive microns downwards, or about the size of the common pathogenic micro-organisms. Owing to their minute size these particles may be present in air in dangerous concentration without being visible to the eye or in any other way noticeable to the senses, so in a phthisis-producing industry it is expedient to sample the air for dust as one samples for gas in a "gassy" mine.

The Lungs and Dust.—The lungs have a very considerable power of ridding themselves of inhaled particles, and some dusts, ike coal-dust, are much more readily got rid of than others while, n the case of a phthisis-producing dust, accumulation readily gets ahead of elimination, so quite small quantities of air-borne dust may be dangerous. It is owing to this cumulative factor hat duration and continuity of exposure are of importance as well as concentration in the air. While the average incidence f miners' phthisis on the gold-mines of the Witwatersrand is nder 3% per annum of the underground population the incience rises as high as 10% per annum in the case of miners of 13 ears' service and over.

Dust Cells.—A certain proportion of the fine dust inhaled runs he gauntlet of the upper respiratory passages and gets right own into their minute blind extremities, the alveoli. In silicosis s in pulmonary tuberculosis "lesion means arrest" and the ust particles are arrested by being taken up by certain cells nown as dust cells. The dust cells are a variety of the phagoytes of Metchnikoff and, when dust-laden, they aggregate toether forming small masses or pseudo-tubercles. These pseudoubercles may be found on the alveolar walls, under the pleura nd in the lymphatic channels which they obstruct. The dustontaining cells forming the pseudo-tubercles tend to degenerate nd become fibrous tissue thus forming the fibroid nodules charcteristic of the early stage of silicosis.

Prevention.—It is the fine dust that matters and, in mines here a phthisis-producing rock is dealt with, the chief sources f fine dust are blasting and rock-cutting with machines. From e point of view of prevention, in industries where blasting is ractised, the workers should not return to the working-place ntil after all dust and fume have been blown away. Ventilation ith good currents of dust-free air is the great safeguard because, y treating the air-borne dust as a gas, it can be diluted down wards a safe level. What is a safe level? When one has to deal ith daily exposure over many years, perhaps about one milliamme of dust per cu. metre of air. The fine dust is only a small oportion by weight of the total air-borne particles, but inudes the majority of particles by enumeration. A sample of r-borne dust of 2 milligrammes per cu. metre as determined by e method in use on the Witwatersrand corresponds to about o particles of fine dust per cu. cm. of air (counted by Kitze niometer). The other great safeguard is "working wet" and e chief source of the dust associated with machine drilling is "sludging" with air. When it is practicable to sludge with water only, machines raise much less dust. Water-sprays should be in continuous use and the roof, walls and floor of the working-place kept wet. All broken rock should be thoroughly wetted before moving (*see* MINING).

A machine may be in good order for rock-cutting and in bad order for dust-control and should be inspected from the latter point of view as well as the former. A hand-drill is more difficult to keep in order for dust-control than is the larger machine and it is doubtful if it is possible to secure safe conditions if hand-drills are used dry when cutting phthisis-producing rock. In all phthisis-producing industries, apart from working wet, it is wise to think of the fine air-borne dust as a gas and make every possible use of exhaust-hoods and abstractors; while sources of dust escaping to the air should, as far as possible, be located and enclosed.

There are two important factors in the severe forms of miners' phthisis:—

(1) The phthisis-producing dust.

(2) The tubercle bacillus.

Carriers.—The modern view of pulmonary tuberculosis as met with in the adult population of civilised countries is that it is related to re-infection by the obvious route of inhalation. Under experimental conditions the presence of dust in the air, together with the tubercle bacillus, renders the susceptible animal much more liable to infection by inhalation. It is on account of this association that, in a phthisis-producing industry, one must strive not only to eliminate dust but also to eliminate the tubercle bacillus. The only practicable step towards the latter ideal is to detect and remove the "carrier," *i.e.*, the sufferer from open tuberculosis. For the sake of others as well as for their own, sufferers from tuberculosis should not be allowed to work at a phthisis-producing industry. Tuberculosis, of course, is not a compensatible occupational disease, but it might well be so regarded in a phthisis-producing industry for, although pulmonary tuberculosis is not miners' phthisis, practically all grave miners' phthisis is associated with pulmonary tuberculosis.

(A. MAV.)

MINING (*see* 18.528).—Since 1910 there has not been much change or development in the methods of working as applied to the extraction of mineral ores and other substances from veins and stratified deposits. This is, perhaps, more particularly the case in regard to coal and stratified deposits than of metalliferous ores occurring in veins. The development in respect of the former lies chiefly in the direction of the machinery used in the mines and its application, more particularly at the working face, and especially that used in the getting and transporting the coal at the faces.

In the working of metalliferous veins, while the standard methods of extracting the ore by overhand or underhand stoping have changed little, a more definite classification than existed formerly has grown up respecting the application of these methods to given local conditions. Comparatively thin veins, with a steep pitch (dip), are developed by a series of drifts (levels), and above each of these overhand stopes are opened for extracting the ore, the working being advanced upward. The broken ore is run through chutes (mills or passes) to the level below, in which it is conveyed in trams by hand or mechanical power to the shaft or through an adit (tunnel) to the surface. For thicker veins, especially those with a steep dip, underhand stoping is occasionally employed, the advance being forward and downward toward the haulage level. In the case of flat veins or of bedded deposits breast-stoping is used, the details of which much resemble those of underhand stoping. In all of these methods, the roof of the deposit (hanging wall) is supported by pillars of ore, by props, balks of timber (stulls), by "square-set" timbering or by masses of waste ore and rock (filling) carried by stulls. Sometimes stopes are completely filled with waste.

Shrinkage Stopes.—There are a variety of overhand stopes which have been more widely employed than formerly for both narrow and wide steeply dipping veins. In these stopes the broken ore accumulates until the stope is complete, thus making artificial support for the walls of the stope unnecessary. Since rock when broken increases in bulk, from 25 to 40% of the ore is drawn from the stope as it advances to leave room at the top for the miners, who stand on the broken ore while drilling. This method is applicable only to those cases where the inclination and width of the vein are great enough to allow of the broken ore sliding down freely to the stope floor (footwall). Finally, after all the ore has been drawn off, the stope is allowed to cave in or is filled with waste. In principle, the shrinkage stope is identical with the "battery-breast," commonly used in fairly thick coal seams, when the pitch exceeds about 35° to the horizontal.

Caving Systems.—The prototype of these, long employed in certain British iron mines, is known in the haematite iron ore mines of Lancashire and Cumberland as the caving system. In the United States caving was first used for the soft iron ores of northern Michigan. More recently, it has been extensively applied to the iron deposits of the Mesabi district, Minnesota, and to some large copper deposits in the south-west of the United States. The chief requisites for the successful application of caving methods are: (1) massive deposits of relatively cheap minerals; (2) ore-bodies of large horizontal dimensions, overlaid by a capping varying in character from earthy soil or glacial drift to firm rock; (3) large-scale work. There are three distinct methods: top-slicing, block-caving and sub-level caving. The salient features of all are: (*a*) horizontal subdivision of the ore-body into floors; (*b*) subdivision of each floor into small slices or blocks which are mined separately; (*c*) delivery of the broken ore through chutes to the haulage-ways below and thence to the shafts; (*d*) as the ore is removed, the overlying capping must gradually cave in and settle.

The period 1910–25 was marked by a wider application of the slicing and caving methods, especially for large low-grade deposits of disseminated copper ore. More deposits of this type have been developed and worked in recent years than ever before, many variations in details being introduced to suit the dimensions of the ore-body, its depth below the surface and the character of ore and of the super-incumbent strata or capping. All this has brought a more definite understanding of the applicability and limitations of the caving systems, as determined by existing local conditions.

Some prominent examples of the newer mines, in which different forms of slicing and caving have been adopted, follow.

Inspiration Mine, Arizona.—The ore-body is a massive deposit of disseminated sulphide of copper (calcopyrite), containing about 100,000,000 tons of low-grade ore, and overlaid by a valueless capping, 30 to 350 ft. thick. A variation of the caving system is used, known as "block-caving." The ore-body is intersected at vertical intervals of 150 ft. by main haulage levels, connecting with the winding shafts (fig. 1). Above the haulage levels are long chute-raises, inclined at 50° to the horizontal, from which numerous short secondary raises ("finger-raises") are driven to a system of sub-level drifts, 35 ft. apart vertically and 50 ft. horizontally. The ore developed by the sub-level drifts is thus divided into small "blocks," which are undercut and broken up by blasting out the supporti pillars between the drifts. The broken ore is drawn down throug the branching finger-raises underneath, into the main raises a thence to the haulage levels, the flow being controlled by gates. the upper part of the ore-body is thus removed, the capping cav in on top of the solid unmined ore below. (For full details, see *Tran Amer. Inst. Mining Eng.*, vol. 55, p. 218; vol. 59, pp. 299, 305; v 66, p. 127.) Block-caving, similar to that of the Inspiration mine, also used by the Ohio Copper Co., Bingham, Utah, and the Neva Consolidated Copper Co., Ely, Nev.

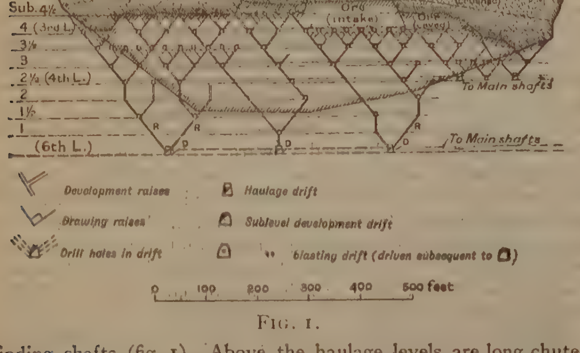

FIG. 1.

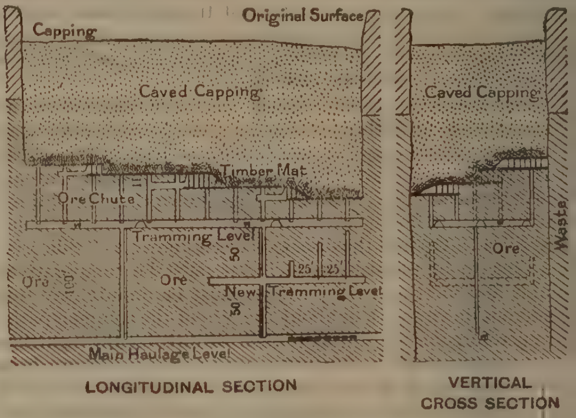
Arizona Copper Co.—A top-slicing method (fig. 2) is applied large bodies of soft ore, carrying 2 to 4% copper. A main haula road is driven near the bottom of the ore-body, and above it a intermediate working levels, 50 to 60 ft. apart vertically. The comprise a rectangular system of tramming drifts and cross-cu from which chute-raises are made into the ore above at 25 to 30 intervals. Starting from the tops of these raises, horizontal slices ore, 7 to 15 ft. thick, are blasted out and the broken ore is run do through the raises to the tramming level. Thence it is conveyed the nearest main raise, connecting with the haulage road belo (For details of the slicing operations and the manner in which t overlying capping caves in as the successive slices are removed, 18.532.)



LONGITUDINAL SECTION

VERTICAL CROSS SECTION

FIG. 2.

These modifications of top-slicing consist chiefly in making rais from the intermediate tramming levels at short intervals, to minim the labour cost of handling the ore mined in the slices. In one of t Arizona Copper Co.'s mines a further saving has been effected omitting the tramming levels and the small raises from them. main drift is driven longitudinally through the axis of the ore-bod just below the roof or capping, and from it, at right angles, cro cuts, 40 ft. apart, to the walls. The panels or blocks of ore betwe the cross-cuts are sliced back from the walls of the ore-body towar the main drift. On each side of the latter a pillar is left, which finally sliced back from its end, in completing a floor. While o floor is being mined, the next, 11 ft. below, is in preparation. Th method of panel slicing has recently been adopted successfully in t Herman gold mine, California. The vein dips 45° to 60°, and t panels are laid out at an inclination of 52°, across the ore-body. To slicing is also used in many massive deposits of low-grade copper o for example: Cumberland-Ely, Nev.; Cananea, Mexico; Mia Ariz.; Bingham, Utah; and mines of the Calumet & Arizona Mini Co., Arizona. At the last-named property, the older caving meth has been replaced by a modification called the Mitchell top-slici system, found economical in reducing the shovelling required.

Other Variations.—In a number of important mines working la ore-bodies, special conditions have been dealt with by combining t or more of the methods referred to above. Examples are to be fou in the mines of the Braden Copper Co., Chile; New Jersey Zinc C Franklin, N. J.; Utah Copper Co. (Boston mine); Ray Consol. Co per Co., Ariz.; Homestake Gold-Mining Co., S.D., and the De Bee Mining Co., South Africa. In most cases, operations begin by shri age stoping, after which the intervening pillars are mined by to slicing, block-caving or sub-level caving, the object aimed at bei the getting of as high a total tonnage extraction as possible, that obviating loss occasioned by leaving ore in permanent pillars through mixture with waste material.

Stripping Superficial Ore Deposits.—This old mode of attac ing shallow deposits of large horizontal area was oftener resort to in the period 1910–25 than previously, and was applied deeper ore-bodies than formerly were considered capable being mined by stripping.

Standard Methods.—Standardisation of methods of worki when practicable probably promotes efficiency and economy

peration. Seams of coal and some regular bedded deposits
f the base metals, owing to their comparative uniformity of
eological occurrence, can be worked to a greater degree by
tandardised methods than most metalliferous deposits, which
ary greatly in their physical characteristics. A notable instance
o the contrary is perhaps that of the Banket deposits of the
Rand, Transvaal, which are in the nature of highly inclined beds
f conglomerate. (See the useful discussion by C. A. Mitke,
Mining Methods of the United Verde Extension Mining Com-
any, Arizona," *Trans. Amer. Inst. Mining Engs.*, vol. 61, p. 188.)
n the three years 1922–5 a "Committee of One Hundred"
f the Amer. Inst. Mining Engs. (comprising 13 sub-committees)
ollected and published descriptions of the mining methods in
he principal districts of the United States. It was planned to
assify these data, with a view still further to standardise mining
ractice for the different kinds and shapes of ore deposit.

In many mining operations there is a stronger tendency
oward standardisation of details. Thus, some mining companies
ave adopted standard "rounds" of holes for shaft-sinking,
rifting, cross-cutting, raising and stoping. The foremen are
rnished with instruction sheets which specify the position,
epth and charge of explosive for each hole. The miners are
equired to follow these instructions instead of doing their work
accordance with their own individual ideas. The adoption of
ch methods has been assisted by the greater attention now
ven to what may be termed efficiency engineering. Many
rge mines have "efficiency engineers," who study in detail the
erformance of both men and machinery, thus improving the
uality and amount of work done. In Great Britain too, quite
tely, attention is being directed in some enlightened quarters
the psychological side of mining with a view to ensuring
eater efficiency.

Directed toward this end also are the movements inaugurated by
veral mining companies to instruct their employees in the best
ethods of doing their work. Thus, an education department is
aintained by the Phelps-Dodge Corp., of New York, which oper-
es a number of mines in the southwest of the United States. Lec-
res are delivered to the miners on practical mining topics, followed
examinations. The North Butte Mining Co., of Montana, has
so standardised the details of many underground operations. The
st of these education departments is considerable, but is amply
stified by the results. A wholesome spirit of rivalry is encouraged
nongst the miners and their ambition is aroused; hence, better
rk is done, the *morale* of the whole force is raised, and better rela-
ns are established between the employees and the mine manage-
ent. The principles of standardisation have also been increasingly
plied to the design of mining appliances and machines.

Blasting.—Explosives for blasting rock and ores underwent
nsiderable change in composition during 1915–25, and tests
ve supplied valuable data respecting the disruptive and
opulsive forces and the sensitiveness of the types and grades of
namite, leading to a better understanding of their suitability
different kinds of service. Explosives for coal-mines, especially
ose in which dangerous gases occur or which are dry and
sty, must be so constituted that ordinary charges will not
oduce a flame of sufficient intensity and duration to ignite
plosive mixtures of gas and air. These comprise the tested
ermitted explosives," lists of which are published in coal-
ning countries and revised from time to time, to keep them up
date. In Europe their use under certain conditions—condi-
ns which exist in the majority of the coal mines—is required
law. In the United States the lists appear in publications of
Bureau of Mines. The bureau can only recommend them,
ugh legal requirements exist in some of the states.

" Permitted explosives" have certain characteristic ingredi-
s: (*a*) ammonium nitrate; (*b*) salts containing water of crys-
isation, which, being liberated and vaporised by the heat of
losion, reduces the flame temperature; (*c*) organic nitrates
er than nitro-glycerine, *e.g.*, nitro-starch; (*d*) nitro-glycerine,
ed with free water or an excess of carbon. It was formerly
umed that nitro-glycerine compounds and other detonating
losives were not suitable for collieries, because, due to market
uirements, excessive shattering of coal is undesirable (except
coke-making); but low-strength, "short-flame" dynamites are now being satisfactorily used. While no explosive can be absolutely safe in gassy mines, those in the "permitted" lists are relatively safe. The standard tests vary as between countries; that of the United States, which is now given, is less drastic than that operative in Great Britain. In the U.S.A. an explosive is accepted for the list when a charge of 680 gm. (1½ lb.) does not ignite gas or coal-dust; it is not accepted if a charge of 250 gm. does cause ignition. In 1912 the permitted list of the U.S. Bureau of Mines comprised 96 kinds and grades of safety explosive; in Jan. 1924 the number had increased to 158, many being almost identical in composition. The United States is the largest user of "permitted explosives" in the world, the quantity consumed having more than doubled in 1912–25.

Blasting methods in the United States have been improved by the introduction of "delay action" electrical fuses. In work like tunnelling (cross measure or stone drifting) and shaft-sinking, where rounds of charged holes are best fired in volleys, these special fuses save time, as the miners need not return to the working place after each volley to prepare for the next. The entire round is wired, as if all the holes were to be fired simultaneously, and there is but one application of the current. The groups of holes explode successively, in the desired order and at intervals of about one second, by using "no-delay" fuses for the first group and "first-delay" and "second-delay" fuses for the following groups. In British coal-mining, volley firing of charges is not permitted by the laws regulating the industry.

Construction of Delay Fuses.—The platinum bridge in the cap shell, between the terminals of fuse wires, is not embedded in the fulminating charge itself, so as to explode it directly, but ignites a short piece of slow-burning ordinary fuse, which in turn explodes the fulminate. The delay interval depends on the length of ordinary fuse used. Another new device for the same purpose is the electric fuse-igniter. A special electric cap contains a small charge of fine-grain black powder, beyond which is a piece of ordinary fuse, with a cap on the end to be placed in the dynamite cartridge. For blasting with black powder, no cap is put on the ordinary fuse.

Mine Hygiene.—Improvements made in the years 1910–25 were chiefly in five directions: (1) better ventilation of mine workings; (2) enforcement of dust-prevention regulations and of regulations requiring the adulteration of coal-dust in the mine by the admixture therewith of inert dust; (3) introduction of new types of blasting explosives, so constituted as to minimise the quantity of deleterious gases evolved; (4) adoption of precautions with the object of producing more perfect combustion of explosives, and the consequent reduction or prevention of the formation of the poisonous carbon monoxide; (5) study and better understanding of special miners' diseases and their treatment. (*See* INDUSTRIAL WELFARE.)

Ventilation.—Formerly, artificial ventilation by fans or blowers was provided only for collieries, to dilute and sweep out gases emanating from the coal and surrounding strata. In recent years, mechanical ventilators have been increasingly applied in the ventilation of metalliferous mines also.

About the year 1902 the high mortality amongst the miners of some districts, especially on the Rand, South Africa, began to attract attention. Investigation showed that acute lung trouble ("miner's phthisis" or silicosis) is caused by inhaling dust from drilling in dry silicious rock or ore. In 1903 a Government Commission was appointed to study the conditions in the Transvaal gold-mines. Their report led to a demand for better ventilation of the mine workings, and the adoption of water-spraying devices to allay the dust arising from the operation of drilling. Revised and more stringent regulations were enacted in 1913. Other governmental investigations were made in Cornwall and the ganister mines of the Midlands, England, Australia and New Zealand, and in the United States by the Bureau of Mines. In 1911 one of the large gold-mining companies in the Transvaal, the Rand Mines (Ltd.), established a department of sanitation, to deal in general with miners' living and working conditions and diseases. The department's activities now cover a large number of the mines of the district, employing between 55,000 and 65,000 men, and marked benefits have resulted from this important movement, which is gaining in strength.

Tests of the gases from blasting explosives have revealed the extent to which they may vitiate mine air. One pound of standard dynamite produces about 10 cu. ft. of gas, which, due to incomplete detonation, often contains 25 to 30% of carbon monoxide. Since, for safety, this actively poisonous gas should be diluted to about 0·01 of 1%, it is evident that natural ventilation cannot always be relied upon, and mechanical ventilators have been installed for many metalliferous mines. Several new types of high explosives have recently been introduced, so compounded that they produce much less carbon monoxide (CO) and methane (CH_4) than the standard ("straight") dynamites. They are therefore particularly useful in poorly ventilated mine workings, as headings where, in order to secure ventilation (in coal mines), bratticing or air pipes are necessary. Furthermore, there has been increased insistence on the use of high-strength caps or detonators, since imperfectly detonated explosives of all kinds produce an excessive amount of carbon monoxide.

Explosions in Coal Mines.—Advances have taken place in the appliances for fighting mine fires, in the modes of preventing and dealing with gas and dust explosions in collieries and in the design of safety lamps. Coal dust explosions are generally much more serious in bituminous than in anthracite mines. Most explosions in anthracite mines are of gas, sometimes aided by presence of dust. Many investigations of coal-dust explosions have been made in Europe since 1880, but some of the phenomena attending their initiation and propagation have long been imperfectly understood.

Since Professor Galloway (afterwards Sir William Galloway) first drew attention, about 1880, to the dangers arising from coal dust and the brothers Atkinson (Inspectors of Mines) wrote their book on colliery explosives, Sir William Garforth, after the Altofts explosion in Yorkshire, described the arresting effects of stone-dust on the explosive blast, and thereafter the Mining Association of Great Britain established a plant near Altofts for carrying out large scale experiments and did excellent work. Eventually the Home Office took over the plant and, transporting it to Eskmeals in Cumberland, added to it and extended the scale of the experiments.

The results of the elaborate work of the Home Office committees, extending over the period 1910–4, was published before the World War, and after the War a comprehensive set of regulations was established by the British Govt. for the purpose of reducing the accumulations of coal-dust in the mine and rendering such dust as remains uninflammable by reason of the admixture of inert and innocuous dust in stated proportions and of a specified fineness. Experiments were also carried out at the Liévin testing station in France, commencing in 1907, and later in Belgium and in Germany, and by the U.S.A. Bureau of Mines at their testing plant and Brunton experimental mine, near Pittsburgh (since 1909). Amongst the facts demonstrated are:—

(*a*) The blasting of a single hole, charged with long-flame explosive (gunpowder or high explosive), may cause the ignition of coal-dust; (*b*) respecting the initiation of an explosion, if enough dry coal-dust is present, it is immaterial whether the air at the point of origin is quiescent or moving in either direction; (*c*) quantities of dust as small as ⅕ oz. per cu. ft. of space (or 1 lb. per linear ft. of an ordinary roadway in the mine) will propagate an explosion; (*d*) in presence of sufficient dust, an explosion may be produced at will in a roadway, even when the roof, sides and floor are wet to the touch owing to the presence of dry dust on the timbers, etc.; (*e*) the force of a coal-dust explosion usually increases in violence as it is propagated through a mine working and may reach its maximum after travelling 500 to 800 ft. from the place of origin; (*f*) pressures as high as 120 lb. per sq. in. have been measured at right angles to the direction of movement of an explosion, the pressure in the line of advance being doubtless much greater.

Stone-dust Barriers.—Stone-dust barriers, for checking or preventing the propagation of coal-dust explosions, were devised by J. Taffanel and modified by G. S. Rice, of the U.S. Bureau of Mines, but constitute a doubtful safeguard. They consist of series of wide shelves, set across the mine gangway near the roof, each loaded with rock-dust. The shelves are tripped mechanically by the advance force waves of an explosion, being set to operate at certain air velocities produced by the explosion. From two to three tons of rock-dust are thus discharged in a dense cloud, in front of the advancing explosion wave, and, mixing with the coal-dust-laden atmosphere of the gangway, prevent propagation of the explosion.

It would appear that the only really safe precaution to take the thorough admixture with the coal-dust of the fine stone-dus It was until quite recently considered that the presence of 30 of inert dust secured safety, but the most recent experiments Professor Wheeler, of the British Mines Department of Safety the Mines' Research Board, shows that this may prove insufficie with coal-dust of high volatile content, and that as much as 50 or more may be necessary in some cases. Great interest "stone dusting" is now being manifested in mining circle See the publications issued by the British Mines Departme and the U.S. Bureau of Mines, *Bull.* No. 225 (1924).

Gas Helmets, etc.—Gas helmets and oxygen breathing-appar tus, long used in mine rescue work, have undergone conside able improvement in point of construction, though no ne principle can be said to have been evolved.

Winding Engines.—Power plants (frequently hydroelectr except in the case of Great Britain) have been established many mining districts, and supply electric current at cheap rates than are possible for equivalent steam power. Electri driven winding engines are consequently used in much great numbers than formerly and in Great Britain, though electrici is seldom obtainable from water power, electric hoists ha increased in use at collieries which have in some instanc established large power plants, *e.g.*, at Powell Duffryn Collie in South Wales. The control mechanism of electric winders is perfected that these engines are as manageable as the best stea winding engines. The large variations in load, unavoidable winding operations, and very disadvantageous for electric tran mission of power, are successfully dealt with by the "equalisi systems" of winding or hoisting, the first of which, the Siemen Ilgner, was introduced just previous to 1906. Modificatio of it, based chiefly on the mode of control, are the Westinghou and the Ward-Leonard. The design and operation of all of the devices are based on the principle that, when a motor receiv electric current, it will deliver mechanical power; conversel when driven by mechanical power, the motor becomes in effe a generator and furnishes electric current. The alternating cu rent usually supplied to a mine is first reduced to about 500 vol and then goes to a motor-generator set, comprising a shunt induction motor, which drives a direct-current generator a a heavy fly-wheel, all on a common shaft. This set is in consta motion, though not at constant speed. From the generator t current goes to a winding engine motor, which drives a pair drums on the drum shaft.

At the beginning of a winding cycle, the winding engi motor receives current from the motor-generator set; but, aft the descending cage has reached a point where the trip can completed by the weight of the rope, the winding engine motor driven by the drum, and therefore supplies current to the gener tor of the motor-generator set. Thus, part of the recovered pow is stored in the fly-wheel, while the remainder is expended driving the induction motor as a generator, thereby causing to deliver current to the external circuit or power service. T fly-wheel cuts down the peaks of the load curve. Since 1915, number of these plants have been erected; they are costly a suitable only where the hoisting is nearly continuous and hig peak loads are heavily penalised in the power service.

Underground Haulage.—For locomotive haulage, the electr trolley system was in 1925 still first in importance, though t use of this system is not permitted in gassy and dusty coa mines in Great Britain; next to this were the compressed-a locomotives, very rarely used in Great Britain, if at all. Storag battery locomotives, though invented many years ago, we rarely used until about 1911 and in 1925 were employed to a li ited extent only in the mines of the United States and the co tinent of Europe; their use in British coal mines is at the prese time under consideration and a prize was recently offered for safe and practical locomotive.

Their construction is simple, and, as they carry their pow with them, they have the advantage of being able to opera herever a rail track is laid, without the necessity of erecting a rolley wire. They are best suited to short distance haulage and ght service, as for gathering individual tubs or cars from the orking places and making them up into trains or sets on the ain haulage roads, or what is termed "secondary haulage." he maximum speed is about five miles per hour and easy track radients are necessary. Their chief disadvantage is high first ost. A few combined trolley and storage-battery mine locomoves have been built, but they are unlikely to have a wide pplication. Gasoline locomotives were introduced in the U.S.A. ines before 1905, but were not much used until about 1912. ike storage-battery and compressed-air locomotives, they have he advantage of carrying their own power. Ordinary speeds ange from four to ten m. per hour. Although reasonable in first ost and running expenses, gasoline locomotives can be employed underground only where there is freedom from inflamable gas and dust and where there is abundant and active entilation, because their exhaust usually contains enough arbon monoxide gas to require a large amount of dilution. Their onsumption of gasoline at full load is, say, 0·7 to 1·2 lb. per .P.; considerably more at half speed and load. (U.S. Bureau of Iines, *Bull. No. 74.*)

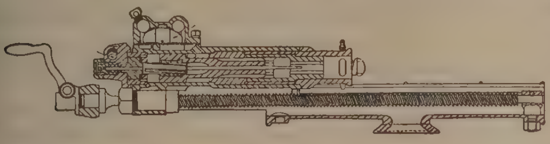


FIG. 3.

Shovelling Machines.—These were introduced in the U.S.A. bout 1907 for loading broken coal or ore underground. The onditions obtaining in British coal-mines do not permit of the echanical shovelling of coal at the face. The first was the hew machine, a dipper shovel of small size, operated by elecicity or compressed air and suitable for use in stopes in a flating deposit or in a tunnel. A later design, the Myers-Whaley, onsists of a large scoop, which is thrust into the pile of broken e or rock, then lifted and dumped backward on to a short avelling belt conveyer, for loading into a mine car in the rear. his machine occupies but little space. In 1915 two of them were stalled in a long haulage drift, 14 ft. wide by 10 ft. high, in the rown mines, Transvaal. Interest in the subject has been stimated by the high wages now prevailing in most mining regions. here wages are low, however, they cannot compete with hand ading. The use of mechanical loaders has increased enormously the United States since 1915 and new designs frequently apear. A monograph of 638 pp. on *Mechanical Underground oading in Metal Mines*, by C. E. Van Barneveld, of the Bureau Mines, was published in 1925.

Machine Drills.—Important changes were made during 1910–25, pecially in the further development of the "hammer" drills hich for many kinds of service have largely replaced standard pes of piston machines. In the hammer drill, the bit is held ationary in the front end of the machine, and is struck a rapid ccession of blows by the reciprocating piston-like hammer. s the bit does not reciprocate, its cutting edge being always contact with the rock, except during the slight rebound caused each blow of the hammer, automatic means must be provided r removing the sludge and thus keeping the hole clean while illing. Hammer drills therefore use hollow bits, through which a jet of compressed air or water is discharged at the bottom of the hole, thus driving out the cuttings. When compressed air is used, and the rock is dry, the dust discharged from the hole is annoying and hurtful to the drill-runner. Hence, a water jet is in common use. The water is delivered under pressure from a 15-gal. to 18-gal. tank, through a short length of hose. Pressure in the tank is produced by connecting it by another hose with the compressed-air pipe.

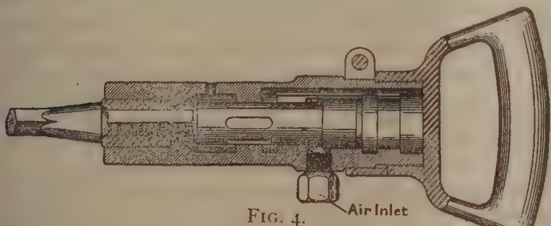

FIG. 4.

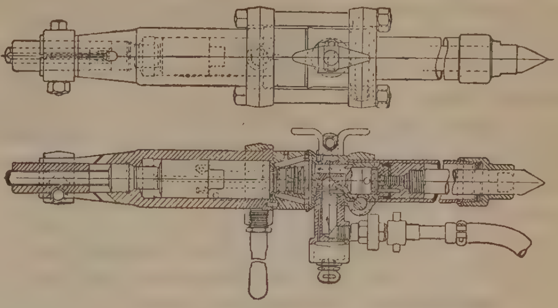

FIG. 5.

Hammer drills are of three types: (*a*) Large machines (fig. 3), corresponding in size and weight with ordinary piston drills, mounted on tripod or column and used for the same kinds of work; (*b*) the small D-handle and cross-handle drills for making holes pointing downward, as in shaft-sinking (fig. 4); (*c*) machines having an automatic air-feed standard, used chiefly for holes directed steeply upward, as in most stoping operations (fig. 5). Machines of classes (*b*) and (*c*) have the advantages of lower first cost, of being operated by one man instead of two, and of eliminating the time lost in cleaning out the hole and in "setting up," as for the standard piston drills and class (*a*) hammer drills. In most rocks and ores, these hammer drills, therefore, do faster work than piston drills. The hammer drill is also applied to the breaking down of coal, and is used with advantage at many European coal mines.

Deep Boring.—In recent years, for prospecting by boring, there has been a great increase in the use of the "churn drill"; that is, a drop drill, suspended by a rope from the operating machinery on the surface, and similar in many respects to the standard oil-well drilling plant. For deep boring, the oil-well "rig," the churn drill and the diamond drill divide the field among them. During the decade 1915–25, many oil and natural gas wells were bored to depths of 4,000 to 5,000 ft., and a few exploratory holes (in Pennsylvania and West Virginia) reached depths of 7,000 to 7,350 feet. For holes of a few hundred ft. in depth, and when cores are desired, the rotary "shot-boring" method, based upon the old Davis Calyx drill, has continued in use to some extent.

For rotary boring in the softer strata, the "fish-tail" bit, with two cutting edges somewhat resembling those of a large carpenter's auger, has come into much wider use for oil and gas wells. In 1908 the Sharp and Hughes cone-bit (fig. 6) was introduced for boring in hard rock, and has been widely used in some of the petroleum and natural gas-fields. It consists of a pair of hardened

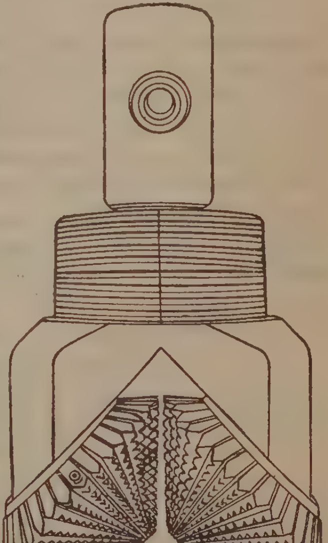

FIG. 6.

steel cones, with serrated or toothed surfaces, revolving on bronze bearings. As the drill rod rotates, the cones roll under pressure upon the rock, crushing and chipping it away. When dull, the cones are readily replaced. These bits in some cases bore as much as 100 ft. of hole in 24 hours. In boring oil wells through soft strata or shattered rock, the sides of the hole often cave before the lining or casing pipe is put in. To overcome this difficulty, "mud-laden" water has been used in the boring operations instead of the ordinary wash-water. Finely divided, clayey material that will remain in suspension for a considerable period of time is employed. The mixture of mud and water should have a specific gravity high enough to afford a counter-pressure that will aid in supporting the walls of the hole; a specific gravity of about 1·33 is usually sufficient. The pressure in the bore-hole is thus kept in approximate equilibrium until the hole can be lined with piping (casing) or screens are set in the oil-bearing strata and cemented in place. This method was introduced in Europe, about 1895, for sinking cylindrical mine shafts in unstable, water-bearing soil by boring. About 1901 it was adopted for boring oil wells in Texas and Louisiana, and since 1906 has been successfully used in a large number of cases. (*See* COAL; COPPER; EXPLOSIVES.)

MINNEAPOLIS, Minn., U.S.A. (*see* 18.546), increased in population from 301,408 in 1910 to 380,582 in 1920, and 425,435 (Census Bureau estimate) in 1925. Among the 88,248 of foreign birth (1920), Swedes (26,515) and Norwegians (16,389) predominated. The total value of manufactured products was $165,405,000 in 1909; $491,383,000 in 1919; $338,329,208 in 1923. Flour-mills (output, 1924, 11,679,130 bbl.) and grain elevators (capacity, 1925, over 56,000,000 bu. kept their dominating place in the city's industries, but the reduction of freight rates *via* the Great Lakes to approximately the pre-War basis, while all-rail rates to the East remained 65% higher, was resulting in the transfer of some of the milling business to Buffalo and other points in the East.

Ranking next to flour in 1923 were motor vehicles and bodies and parts; linseed oil, cake and meal; bread and other bakery products; and knit goods. The vast lumber industry dwindled, with the gradual exhaustion of the pine lands, from a maximum of 600,000,000 ft. sawed in 1899 until in 1920 the last mill went out of existence. Minneapolis is the seat of the ninth Federal Reserve Bank. Bank deposits on Jan. 1 1925, were $319,388,000. The combined manufacturing and wholesaling market in 1924 was estimated at $1,300,250,000.

Navigation of the Mississippi river up to the heart of the city was opened on July 3 1917, when the first steamer passed through the recently completed lock. In Nov. 1925, seven motor-bus companies, operating over 2,000 m. of state highways to the north and west, were merged in an auxiliary of the Great Northern Railway. The Great Northern passenger station, which is used by a majority of the railway lines, superseded, in 1914, the older union station.

Registration in the University of Minnesota reached 18,
in 1924–5; its Memorial Stadium, seating 50,200, was opened
1924. Enrolment in the public schools increased 70% betw
1910 and 1925, while the increase in population was 41%. T
park system by 1925 included 4,722 ac.; a playground for ea
sq. m. of residential area; five golf courses; and 56 m. of bou
vards encircling the city, the so-called "Grand Rounds,"
section of which is the Victory Memorial driveway (dedicat
1921). In the summer of 1925 the stream supplying Minneha
Falls, which had been failing for several years, gave out entire
To restore the supply deep wells were dug, from which wa
can be pumped into the creek when necessary.

Minneapolis has a low general death-rate, a low infant m
tality, a high percentage of home ownership and a low percen
age of illiterates and of children engaged in wage-earning occ
pations. Cost of living is below the average for American citi
The non-partisan system of nomination for city offices was p
into effect in 1912. A city-planning commission was establish
in 1919, and a zoning ordinance adopted in 1924. In 1925 a n
charter, providing for a city manager appointed by the legislati
body (the city council) and for a school and library board, w
prepared for submission to the voters.

MINNESOTA (*see* 18.548).—The population of the state in 19
was 2,387,125 as against 2,075,708 in 1910, an increase of 311,41
or 15% for the decade. The total white population was 2,368,93
of whom 1,882,772 were natives and 486,164 foreign bor
Negroes numbered 8,809 and Indians 8,761. The density w
29·5 per sq. m.; 25·7 in 1910. The estimated population in 19
was 2,651,306. The urban population (in places having ov
2,500 inhabitants) was 1,051,593, or 44·1% in 1920; 41·0%
1910. The rural population was 1,335,532, or 55·9% in 191
The following table gives the population and the percentage
increase of cities having more than 15,000 inhabitants in 1920:—

Cities	1920	1910	Increase %	Estimate 1925
Minneapolis . . .	380,582	301,408	26·3	425,435
St. Paul	234,698	214,744	9·3	246,001
Duluth	98,917	78,466	26·1	110,502
Winona	19,143	18,583	3·0	19,459
St. Cloud	15,873	10,600	49·7	18,860
Hibbing	15,089	8,832	70·8	17,955

Agriculture.—There were 188,215 farms in Minnesota in 192
These farms covered 30,040,933 ac., two-thirds of which was in
proved. The total value of farm land and buildings in 1925 wa
$2,396,005,328. The final stage in the state's progress fro
pioneer to diversified farming was marked by the decline
wheat from second to third crop. In the years following 192
the total corn and oat crop was consistently more than fou
times as great as the total wheat crop, both in quantity an
value. The northern part of the state showed a rapid develop
ment in stock-raising and dairying.

Minerals.—About 60% of the output of iron ore in the Unite
States is mined in the three great iron ranges of northern Mi
nesota. The Mesaba range, 110 m. in length, embraces 130 activ
mines. The Vermillion and Cuyana ranges combined form a
additional iron belt of about 50 miles. A total of 44,556,053 ton
of ore, valued at $158,402,788, was shipped from Minnesot
mines in 1923.

Manufactures.—In 1923 Minnesota ranked twelfth among th
states in the value of its manufactures. In the 3,902 establish
ments (not including hand industries) then existing, the averag
number of persons employed was 103,344 and products valued a
$968,476,565 were manufactured. There was a falling off i
manufacturing from 1919, the peak year. The state's five mos
important industries, in the order of the value of products i
1923, were the flour- and grist-mill, slaughtering and meat-pack
ing, dairy and creamery, the manufacture of cars and genera
shop construction and repairs by steam railways and lumber an
timber industries. In flour and butter Minnesota's product
exceed those of any other state. Following 1910 the slaughterin

and meat-packing industries, centred at South St. Paul, showed rapid growth. Because of the depletion of her forests Minnesota dropped from third place among the states in lumber manufac-ure in 1900 to sixteenth place in 1920; but, though lumbering declined, timber manufacturing increased. Iron ore is now worked in huge iron and steel plants on the St. Louis river near Duluth, and farm machinery is manufactured increasingly.

Transportation.—The railway mileage in Minnesota in 1924 was 9,096 an increase of 7·8% since 1908. In 1924 there were 80·2 m. of electric lines, exclusive of city street railways. With the growth of motor traffic, the demand for good roads greatly increased, and the state engaged in road building on an xtensive scale. An amendment to the constitution (1912) uthorised the levy of a one-mill tax, the proceeds to be distrib-ted among the counties and used for road building and main-enance; another amendment (1920) authorised the issue of onds and provided for the taxation of motor vehicles in order to nance a system of state trunk highways covering 7,000 m.; a hird amendment (1924) authorised a tax on gasolene used in motor vehicles and to add the proceeds of the tax to the highway und. There were in 1922 about 107,103 m. of public roads in the tate. The U.S. Govt. completed in 1920 the construction f a dam in the Mississippi between St. Paul and Minne-polis, which by means of locks makes the latter city the ead of navigation on the river. An attempt is being made to evive freighting on the river, between Minneapolis and St. ouis; and the Ford Motor Company's northwest plant, estab-shed in St. Paul and using hydroelectric power from the overnment dam, is both shipping and receiving goods by water.

Education.—In 1923–4, there were 431 high schools, 746 grade chools, 354 consolidated schools and 6,607 rural schools with ,900 teachers and 78,000 pupils, and these schools received, in ddition to local support, state aid. During 1923–4, $59,316,000 as expended on public education. There are six state teachers' olleges and 12 private institutions of collegiate grade. The niversity of Minnesota at Minneapolis comprises 13 colleges nd schools. A noteworthy development in the medical school as its affiliation with the Mayo Clinic at Rochester. In 1915 William J. and Charles H. Mayo, the famous surgeons, estab-shed the Mayo Foundation for Medical Education and Re-arch, endowed it to the amount of $1,500,000 and gave it to the niversity. The university was thus placed in control of prac-cally all medical instruction in Minnesota. In 1924–5 the niversity had 12,736 students, 673 faculty members and 253 uildings. An extensive building programme covering a period 10 years was initiated in 1919, when the Legislature ap-ropriated $5,600,000 for this purpose.

Government.—In 1925 the state government was reorganised combining the existing state boards and commissions into velve departments and creating two new departments, the ecutive council (consisting of the governor, attorney-general, uditor, treasurer and secretary of state), and the Department of dministration and Finance, under the control of a commission three appointed by the governor and removable at pleasure. he three commissioners—the comptroller, commissioner of the dget and commissioner of purchases—have general super-sion and control of the expenditures and personnel of state partments and agencies. The placing of the state's charitable d penal institutions under the Board of Control was com-eted in 1917, and the board in 1925 had charge of 18 in-tutions including the recently established asylum for the in-ne with a special ward for inebriates at Willmar, the state formatory for women at Shakopee and the colony for epileptics Cambridge. The new state prison buildings at Stillwater, mpleted in 1912, cover 22 ac. in a tract of 1,000 acres. Among e duties of the new Department of Conservation are forest nservation, reforestation, and the management of the 20 state rks, eleven of which have areas greater than 100 acres. In dition this department manages the Pillsbury state forest, ss county and the Burntside state forest, St. Louis County. vo Federal forest reserves are also located in the state: Su-rior National Forest in St. Louis, Lake and Cook counties; and Minnesota National Forest in Itasca, Cass and Belltrami counties.

Finance.—On June 30 1925 there were 1,375 banking institutions in Minnesota, of which 1,027 were state banks, 21 trust companies, 7 savings banks and 320 national banks. There are also in the state 85 building and loan associations and one credit union. The Federal Reserve Bank for the ninth district is located in Minneapolis. All banking institutions other than national banks are under the supervision of the commissioner of banks of the State Department of Commerce.

History.—The most important political movement of recent years was the growth of agrarian unrest manifesting itself first in the Non-Partisan League and later in the Farmer-Labour party. From 1919–23 this movement was particularly active and two members of this party were elected to the U.S. Senate—one to fill an unexpired term. In 1924, however, the tide was ebbing; at the presidential election the state was carried by the Republican party, and a Republican replaced one of the Farmer-Labour senators. The membership and power of organised labour fluctuated in a way roughly proportional to the fortunes of the Farmer-Labour party. Two important pieces of legislation in 1910–25 were the primary law (1912), which provides for nomination and election on a non-partisan ballot of all state and local officers except the state executive officers, the railway and warehouse commissioners and the clerk of the Supreme Court and the so-called tonnage tax (1921), a 6% tax on the net value of mined ore. Minnesota ratified the Eighteenth (Prohibition) Federal Amendment Jan. 20 1919. The following governors held office after 1909: Albert Olson Eberhart (Rep.), 1909–15; Winfield Scott Hammond (Dem.) (died in office), Jan.–Dec. 1915; Joseph A. A. Burnquist (Rep.), 1915–21; Jacob A. O. Preus (Rep.), 1921–5; Theodore Christianson (Rep.), 1925– (S. J. B.)

MINORITIES.—Groups of population differing by race or religion from the nation of which they form part. One of the most remarkable characteristics in the evolution of modern nations is their tendency to develop political communities increasingly extensive and increasingly homogeneous. In certain countries, such as France, this assimilation is practically accomplished and there is no longer any question of national minorities. But in some cases fusion does not proceed without resistance, and it may be said that the problem of national minorities arises at the moment of the emergence of important groups of persons differing from the majority by race, language or religion, who aspire to an independent life with regard to that majority. These aspirations may vary from the desire for a simple freedom to develop their own intellectual aims and their own traditions to a demand for administrative autonomy, or even a more highly developed political status, on the model of the Swiss cantons.

Historical Survey.—The modern problem of national minorities is identical with the idea of the " National State " which emerged after the break-up of feudalism. Indeed, from the moment when political unity arose on the basis of national unity, every nation which became conscious of a distinct nationality necessarily aspired to the advantages of a more or less complete political independence. Then at the same period, the exhaustion resulting from the religious wars of the 16th and 17th centuries and the advance of toleration were very favourable to the aspirations of homogeneous people for a certain measure of independence. These aspirations found expression from the 16th century onward in international law in the clauses of certain treaties in virtue of which the contracting parties obtained in favour of subjects whom they had been compelled to detach from their rule, or even for certain peoples of the same religion as their own, guarantees for the free exercise of their religion. (For examples see the Capitulations granted by the Sultan Solyman II. to Francis I. in favour of the Eastern Christians, 1535; the Peace of Augsburg, 1555; Treaty of Westphalia, 1648; Treaty of Oliva, 1660; Treaty of Paris, 1763, etc.). The liberation of the English colonies in America, the Declaration of Independence (1776) and the French Revolution with the Declaration of the Rights of Man (1789), crystallised, to some degree, the modern philosophy of nationality which is translated by the formula, " the right of peoples to self-determination."

In the 19th century this was strengthened by a series of brilliant successes: the achievement of independence successively by the Spanish and Portuguese Colonies in America; the liberation of Greece 1821–30; and of Belgium, 1831–2; the gradual elimination of the Turks from Europe in favour of the Christian peoples of the

Balkans; a series of conferences and of treaties (London, 1830; Paris, 1856; Berlin, 1878, etc.) which contained clauses in favour of certain religious minorities.

THE WORLD WAR AND ITS CONSEQUENCES

The War of 1914 caused a formidable awakening of national aspirations. Italy and Rumania entered the War against the Central Powers in order to realise their national demands; Irish agitation was intensified under war conditions. In 1916 an important congress of nationalities met at Lausanne. As early as Jan. 22 1917 President Wilson laid down as the principle of the future peace:—

> That no nation should seek to extend its polity over any other nation or people, but that every people should be left free to determine its own polity, its own way of development, unhindered, unthreatened, unafraid, the little along with the great and powerful.

Nevertheless, the distribution of the nationalities in Europe is so complex, notably in certain regions where the ethnical elements vary from village to village, that it was evidently impossible in the peace settlement to apply in its integrity the principle of self-determination; it was inevitable that some minorities should remain under the domination of majorities. On the other hand, some majority populations before the War became minorities.

A summary table of European minorities appears in next column.[1]

In Russia there are some 40 different nationalities the statistics of which are ill authenticated. The Union of Soviet Socialist Republics has granted to many nationalities a large measure of autonomy, and comprises at present a great number of republics and autonomous territories.

THE RIGHT OF MINORITIES

In Europe alone the multiplicity of minorities, aggravated by the triumph of certain minorities immediately after the World War, has created an extremely dangerous political situation which is a constant source of disturbance. The Peace Treaties of 1919 sought to alleviate this danger by creating wide and fundamental rights for minorities.

The documents sanctioning these rights are of four kinds:—

1. Special articles in the Peace Treaties concluded by the principal Allied and Associated Powers with Austria (St. Germain, Sept. 10 1919); Bulgaria (Neuilly-on-Seine, Nov. 27 1919); Hungary (Trianon, June 4 1920) and Turkey (Lausanne, July 24 1923).
2. Special Minorities treaties concluded by the principal Allied and Associated Powers with Poland (Feb. 13 1920); Czechoslovakia (Sept. 10 1919); The Serb-Croat-Slovene State (Sept. 10 1919); Rumania (Dec. 9 1919); Greece (Aug. 10 1920). All these treaties have been placed under the Guarantee of the League of Nations.
3. Engagements entered into by certain states with the League of Nations to observe toward their minorities, or certain of those minorities, obligations more or less identical with those laid down in the minority treaties: by Finland and Albania, 1921; Lithuania, 1922; Latvia and Estonia, 1923.
4. Bilateral conventions between certain states: Treaty of Brünn between Austria and Czechoslovakia (June 7 1920); convention between Poland and Danzig (Nov. 9 1920); convention between Germany and Poland (May 15 1922).

The great innovation common to these international engagements is the intervention, for the assurance of the protection of minorities, of a supernational power, hitherto unknown, the League of Nations. Obligations with regard to minorities are henceforth conceived no longer as simple assurances of goodwill of a state towards its subjects of another race, but as international obligations which should be recognised by the state concerned as "fundamental laws," which cannot be contradicted by any other laws, and which are placed under the guarantee of the League of Nations. The Council of the League of Nations has been invested with juridical powers to intervene with the Govt. in case of infringement, or menace of infringement of their obligations with regard to minorities; finally, disputes on questions of law or fact which may arise in the carrying out of the

Country	Majority	Minorities

Hungary . .	7,147,000	Germans, 551,200 Slovaks, 141,800 Rumanians, 23,700 Serbs-Croats-Slovenes, 53,900 Jews, 60,000
Italy . . .	41,000,000	Germans, 280,000 French Vaudois, 85,000 Slovenes, 250,000 Croats, 150,000 Albanians, 80,000 Greeks, 25,000
Yugoslavia . . (Serb-Croat-Slovene State)	9,971,600	Magyars, 472,400 Germans, 518,400 Albanians, 441,500 Rumanians, 229,000 Bulgars and other Slavs, 174,000 Italians, 12,800 Various, 212,000
Albania . . .	817,800	Some thousands of Greeks
Rumania. . .	11,576,000	Magyars, 1,650,500 Germans, 804,000 Ukrainians, 1,100,000 Ruthenes, 793,800 Jews, 770,000 Bulgars, 251,000 Serbs, 62,300 Turcs and Tartars, 230,000 Various, 579,000
Bulgaria . .	3,441,000	Greeks, 48,300 Gipsies, 115,700 Jews, 43,500 Rumanians, 78,000 Turcs and Tartars, 454,700 Various, 676,000
Greece . . .	5,157,000	Albanians, 162,000 Jews, 110,000 Rumanians, 486,700 Turcs and Tartars, 59,000 Various (Slavs, etc.), 500,000
Turkey . . .	8,518,000	Armenians, 40,000 Greeks, 220,000 Gipsies, 23,500 Jews, 68,600 Various, 2,413,000

---

[1] Figures furnished by a minority rarely agree with those given by the majority. The figures marked with an asterisk in this table are derived from the official statistics of the states concerned. Others are taken from recent authoritative works of reference.

said obligations may be referred to the Permanent Court of International Justice, whose decision is final.

Generally speaking, the treaties, conventions or declarations concerning minorities give these guarantees to the minority populations:—

1. Rights equal to those of any nationals of the country to protection of life and liberty and the free exercise of their religion;
2. A special right to the acquisition of the nationality of the country in question and to the exercise of civil and political rights;
3. Free use of their mother tongue in private life, in trade, in religion, in the Press, in publications, in public meetings and in the courts of law; and
4. The right of maintaining at their own expense charitable, religious or educational institutions.
5. In districts in which the minority constitutes a considerable proportion of the population, instruction in the primary schools of the state shall be given in the language of that minority and the minority shall be assured an equitable share in the sums provided by the state and municipal budgets for educational, religious or charitable purposes.

The conditions under which minorities may raise a complaint, and the procedure to be followed by the Secretariat and the Council of the League of Nations are laid down by precise regulations which have been several times revised (Tittoni Report: Resolutions of the Council of Oct. 25 1920; of June 27 1921; of Sept. 5 1923, and June 10 1925; resolutions of the 3rd and 4th Assemblies). An essential condition is that every application which is admitted as being in order is communicated in the first instance to the Govt. of the state against which the complaint is directed for its observations; the second is that every application definitely admitted as in order is examined by the President of the Council assisted by two members of the Council. But the Council is not assumed to be legally and officially informed until one of its members takes it upon himself to draw the attention of the Council to the case in question. When this takes place, the Council "may proceed in any manner and give any instruction that appears to it appropriate and effective in the circumstances."

As a result of this cautious procedure, many complaints transmitted to the Council have not been considered. This failure has caused serious disappointment and has given occasion for numerous grievances. But on the whole the essential rights of minorities are certainly respected, and even the possibility of the bringing of a complaint of the minorities before the Council or the Assembly of the League of Nations inevitably disposes governments to be prudent and moderate in their attitude towards their minorities. Moreover, certain minorities have obtained important advantages through the procedure adopted by the Council. In conclusion, the modern law of minorities as it emerges from the treaties, conventions and declarations enumerated above, has incontestably exercised on the fate of minorities a moderating influence, the great significance of which can hardly be exaggerated.

MINSKY (1856–), the pen name of Nicolas Maximovich Wilenkine, Russian man of letters, was born Jan. 21 1856 at Glubokoe, Vilno (Wilna) province, and was educated at Minsk. He graduated in law at St. Petersburg University, but soon devoted himself wholly to a literary career. His first volume of poems was published in 1877, but was confiscated by the Government and was not re-issued until 1887. It was during the 'eighties that he became well known as a poet of social revolt. In the 'nineties, however, he became one of the leaders of the Russian symbolists. In 1905 he edited with Gorky the socialist paper, *New Life*. Minsky's philosophic ideas are expressed in *In the Light of Inner Revelation* (1890) and *The Religion of the Future* (1905). He also wrote many sonnets, lyrics and a number of plays. His poetical works were published in four volumes in 1907 and appeared in German in 1923. A volume of his works entitled *Echoes* has been translated into English by D. MacAlister (1923).

MINTO, GILBERT JOHN ELLIOTT-MURRAY-KYNYNMOND, 4th Earl of (1845–1914), British politician (*see* 18.564), died at Minto House, Hawick, Scotland, March 1 1914.

MIRBEAU, OCTAVE HENRI MARIE (1850–1917), French dramatist and journalist (*see* 18.574), died in Paris Feb. 16 1917.

MIŠIĆ, ŽIVOJIN (1855–1921), Serbian statesman, was born July 7 1855 at Struganik near Valievo, the son of well-to-do peasant parents. He passed through the old Artillery school in Belgrade and served in the Serbo-Turkish War of 1877 and the Serbo-Bulgarian War of 1885. During the Bosnian annexation crisis he became assistant chief-of-staff to Gen. Putnik, and in this capacity made his name in the first Balkan War, being promoted general. He further distinguished himself in the Bregalnitsa operations during the second Balkan War of 1912–3. When the World War broke out and the Austrians invaded Serbia in Nov. 1914, Mišić was appointed to the command of the I. Army. Mišić's simple and unaffected heroism inspired his soldiers with confidence: his spirit spread to the whole Serbian Army and found expression in the decisive victory of Rudnik early in Dec. by which the Austrians were driven out of Serbia.

Mišić, who had been created voivode after Rudnik, again served with distinction during the retreat of the Serbian Army in the winter of 1915. After a long interval spent in recovering from the strain of the campaign, he resumed command of the I. Army on the Salonika front in Aug. 1917, and in June 1918 was made chief-of-staff. In this position he played a pre-eminent part in elaborating the plan to which the piercing of the Bulgarian front was due. As a convinced believer in the idea of Yugoslav unity, he did all in his power to promote the efforts of the exiled Yugoslav committee to organise Yugoslav legions on every front. He died on Jan. 20 1921.

MISSIONS (*see* 18.583).—The developments of outstanding interest in missionary work since 1910 have been the new spirit of independence in the churches in the mission field, the growth of the spirit of co-operation, and the new educational demands on missionary schools. The first of these tendencies led to considerable transfers of authority from the missions to the churches established by them. The indigenous church rather than the foreign organisation became increasingly responsible for the direction of Christian activities. In the face of the rising spirit of nationalism, evident in so many quarters, it became essential that Christianity should as little as possible bear the character of a foreign religion.

National Christian Councils.—The impulse of the World Missionary Conference held in 1910 quickly extended itself to the mission field. A visit to Asia by the chairman of its continuation committee, Dr. John R. Mott, in 1913–4 led to the formation in India, China and Japan of bodies representative (with one or two exceptions in the case of Japan and China) of all the Christian forces other than Roman Catholicism. These, by a process of evolution, became national Christian councils, and in China and India, in particular, became an active and influential force. While in their beginning missionary initiative played a considerable part, leadership passed increasingly into the hands of Chinese and Indians, who formed in 1925 half or more than half of the members of the councils in their respective countries. A national Christian convention held in Shanghai in 1922 and attended by Chinese Christians and missionaries of all denominations from every part of China, afforded striking evidence of the reality, strength and indigenous character of the Christian movement in China. It was presided over with remarkable ability by a Chinese Christian, Dr. Cheng Ching-yi, and other Chinese Christians took part in guiding the proceedings.

A corresponding growth of co-operation took place among the missionary societies within their own various political boundaries. The Conference of Missionary Societies in Great Britain and Ireland, meeting for the first time in 1911, united all the principal missionary societies in the United Kingdom and Ireland and led to a marked growth in mutual understanding and fellowship and in practical co-operation in many directions. The Foreign Missions Conference of North America (including the United States and Canada), while of older date, made notable progress on similar lines. National missionary organisations were also formed in the Scandinavian countries, in Holland and in Switzerland, the German Missions-Ausschuss being of older date. Internationally, the continuation committee appointed by the World Missionary Conference gave place to the International Missionary Council, the members of which are appointed by the different national missionary organisations.

Education.—Everywhere in the mission field the position of Christian schools was affected by the rapid extension of Government systems of education. The missionary societies recognised that they had to do with an entirely new situation, and endeavoured to meet it by a thorough examination of the new conditions and the demands made by them. In 1919–20 an education commission was sent to India to investigate the problems of rural education and issued a report entitled *Village Education in India*, which exercised a considerable influence on missionary opinion and policy. Two years later a strong commission under the chairmanship of the late Dr. E. D. Burton, president of Chicago University, visited China and produced a valuable Report entitled *Christian Education in China*. In 1921 and 1924 an Education Commission, under the joint auspices of the missionary societies and the Phelps-Stokes Fund, visited, first, West and South Africa and then East Africa, and its two reports, *Education in Africa* and *Education in East Africa*, were recognised not only in missionary but in Government circles as furnishing much needed guidance in regard to the kind of education best suited to Africa. Effective co-operation in education between missions and Government in the British colonies in Africa was furthered by the appointment by the British Secretary of State for the Colonies in 1923 of a permanent Advisory Committee on Native Education in Tropical Africa, and the setting up in most of the colonies of similar advisory bodies on which the missions are represented.

The World War led to the cessation of the work of German missions in most of the territories under the control of the Allied Powers, but in the British Empire in 1925 the restrictions were being relaxed and German missionaries had begun to return to their former fields. In the *World Missionary Atlas* published in March 1925, the numbers of missionaries were given as follows: ordained missionaries from the United States and Canada 3,713; from Great Britain 2,058; from other countries 1,515; laymen, United States and Canada, 1,963; Great Britain 947; other countries 407; unmarried women, United States and Canada, 4,793; Great Britain 2,503; other countries 1,116. It may be interesting to compare the 1925 figures with those for 1907, though these were from another source: the total number of communicant members was 3,614,154 in 1925 as contrasted with 1,817,450 in 1907, while the total Christian community was returned as 8,342,378 as compared with 4,361,138. The total number under instruction in all types of mission schools was 2,440,148 as compared with 1,302,965. The total income of the Protestant missionary societies was given as £14,958,102 (of which the United States contributed £9,736,084 and Great Britain £2,869,353) as compared with £4,473,933 in 1907. The foregoing figures reveal a remarkable increase in the proportionate share of North America in missionary effort.

Roman Catholic Missions.—The figures for Roman Catholic missions for the year 1908 may be compared with those for 1923 published at the Vatican Exhibition, Rome, the earlier ones being shown within parentheses: European priests 8,617 (7,033); native priests 4,095 (5,837); lay helpers 4,018 (5,270); sisters 24,102 (21,320); catechists and teachers 65,641 (catechists 24,524); number of Catholics 12,964,147 (native membership only, 7,441,215); catechumens 1,534,446 (1,517,909); students and children in schools 1,800,000 (906,000); schools 22,358 (24,000); churches and centres 110,932 (71,000). The World War was the cause of a considerable decrease in the number of missionaries, since the various services claimed many of them and a large proportion of these were killed. The possessions of the Allied Powers being closed to German missionaries in the years immediately following the War, the former fields of German societies thus affected were in nearly all cases transferred to other congregations while fresh fields were found for the expelled societies. A regrouping of Roman Catholic missions thus took place on a considerable scale.

An important encyclical (*Maximum illud*) dealing with missionary work was issued by Pope Benedict XV. in 1919, in which extended directions were given for the conduct of missionary work, exaggerated expressions of nationalism were severely condemned, and great emphasis was laid on the importance of developing a native clergy. The first native bishop was to be consecrated in Japan in 1925.

Considerable changes took place in organisation in Europe. The headquarters of the Society for the Propagation of the Faith, the great collecting society of the Roman Catholic Church, were transferred from Lyons to Rome and put expressly under Papal auspices, while its governing body was made fully international. Two other organisations which were established on an international basis under Papal direction are the Society of St. Peter for the training of a native clergy in mission lands and the Missionary Clergy Union, which in 1925 had a membership of 165,000 priests. A notable development after the War was a wider distribution of missionary support among different countries; the pre-eminence of France being no longer so marked as it was. Increased support for missions was forthcoming in Ireland, Holland, Belgium, Switzerland, Spain and Italy, and there was also a revival of missionary interest in Portugal, Bohemia, Hungary and Poland. The financial contributions of the United States grew remarkably and in 1925 exceeded those of any other country, though the number of American missionaries was considerably below that of a good many other countries. Advantage was taken of the presence of many pilgrims in Rome during the Holy Year of 1925 to organise a great missionary exhibition in the grounds of the Vatican. (J. H. O.)

MISSISSIPPI (*see* 18.599).—In 1920 the total population was 1,790,618, being a decrease of 6,496 from the figures for 1910. The negro population was 935,184, or 52% of the total, as compared with 1,009,487, or 56·2% of the total in 1910. The foreign born whites in 1920 numbered 8,019. The density was 38·6 per square mile. The urban population (in places of over 2,500) was 13·4%. The six cities having a population of over 12,000 in 1920, in comparison with the figures of 1910, and their estimated population as on July 1 1925 were:—

	1920	1910	Increase	July 1 1925
			%	Estimate
Meridian	23,399	23,285	0·5	24,312
Jackson	22,817	21,262	7·3	23,098
Vicksburg	18,072	20,814	−13·2	. .
Hattiesburg	13,270	11,733	13·1	14,034
Laurel	13,037	8,465	54·0	15,513
Natchez	12,608	11,791	6·9	13,070

Agriculture.—In 1925 the number of farms in the state was 257,228, of which 107,095 were operated by whites and 150,043 by negroes. There was a decrease both in the number of farms and the farm acreage as compared with 1920, when there were 272,101 farms embracing an acreage of 18,196,972. Farm values also declined during the same period, the total value of farm land and buildings being $459,936,535 in 1925 as compared with $780,896,778 in 1920, giving an average value per farm of $1,788 in 1925, and $2,003 in 1920. The average size of the farms also decreased from 66·9 in 1920 to 62·4 in 1925. Cotton continues the most important crop but the acreage of cotton decreased from 2,948,387 in 1919 to 2,036,766 in 1924. The livestock on the farms on Jan. 1 1925 comprised 141,952 horses, 330,080 mules, 938,024 cattle and 729,165 swine, having a total value of $62,858,000.

Manufactures.—The value of the output from factories increased from $79,550,095 in 1914 and $114,083,861 in 1921 to $178,581,729 in 1923, Mississippi then ranking 34th among the states in the value of manufactured products and 32nd in number of wage earners, the latter numbering 64,452. The capital invested in manufactures increased from $81,005,484 in 1914 to $154,117,337 in 1920, and $197,746,087 in 1923. The chief manufactured articles are lumber and timber products, cottonseed oil and cake, cotton goods, turpentine and rosin and fertilisers. The chief manufacturing centres are Meridian, Jackson, Greenville, Columbus, Laurel, Hattiesburg, Natchez and Vicksburg. The mineral production of the state is small, its total value in 1922 being $1,600,393, composed chiefly of clay products, sand and gravel.

Education and Charities.—Higher education is taken care of by the University of Mississippi at Oxford, the Mississippi State College for Women at Columbus and two Agricultural and Mechanical Colleges. State normal schools are situated at Hattiesburg and Cleveland, in addition to which there are 175 public high schools and 6,800 elementary schools. Separate schools are maintained for the white and coloured children. Education is state supported, being free to all and compulsory between the ages of 7 and 16. The most important development in education was the establishment in 1908 of county agricultural high schools. Every county may establish one for white children and one for negroes, or two counties may combine and create one set of schools for the two counties. These schools receive state aid on the basis of the number of boarding pupils. The total amount expended for education during the year 1923–4 was estimated at $17,837,000, including a state appropriation of $8,837,404. An industrial training school for delinquent and abandoned children was established at Columbus in 1916, and there are also schools for the deaf and dumb and for the blind at Jackson.

Administration and Legislation.—The constitution of 1890, enacted to ensure white supremacy, has been amended with the object of putting the government more within the direct control of the people. In 1916 the initiative and referendum were adopted by an amendment under which an initiative petition must be supported by 7,500 qualified electors, and a referendum petition by 6,000. Any law bill resolution, constitutional amendment or any other legislative measure is a proper subject for such petition. The judiciary consists of the Supreme Court of six judges elected for eight years and circuit and chancery judges elected for four years. A majority of nine jurors may return a verdict in all civil cases in the circuit and chancery courts. The Legislature is elected for four years and meets in regular session biennially. All financial appropriations are made for two years.

The Torrens System of registration of land titles has been in force since 1915. In 1914 a state department of banking was created with a board of bank examiners consisting of three members elected for four years. Bank deposits are guaranteed by the state. A very comprehensive child labour law was passed in 1912. Under its provisions no child under 12 may be employed in any mill or factory and no child under 16 may be employed for more than eight hours per day. No employee is permitted to work in any mill or factory more than 10 hours per day. The enforcement of this law is placed in the hands of the county health officer. In 1916 a pardon board of five members appointed by the governor was created for the purpose of advising on all petitions for pardons. All such petitions must be published for 30 days in the county where the crime was committed. The board can act only in an advisory capacity, the governor being free to follow their advice or not as he may deem best. A state highway commission was also appointed in 1916.

Mississippi was the first state to ratify the Eighteenth (prohibition) Amendment, doing so Jan. 8 1918. The Legislature, however, refused to ratify the Nineteenth (woman suffrage) Amendment in 1919, and it took no action on the proposed Twentieth Amendment regarding child labour.

In 1926 the state was represented in the U.S. Senate by Hubert D. Stephens and Pat Harrison. The following have been governors since 1910: Edmund F. Noel (Dem.), 1908–12; Earl Leroy Brewer (Dem.), 1912–6; Theodore G. Bilbo (Dem.), 1916–20; Lee M. Russell (Dem.), 1920–4; Harry L. Whitfield (Dem.), 1924–

MISSISSIPPI RIVER (*see* 18:604).—The U.S. Govt. continued work on the various engineering projects connected with the Mississippi and its tributaries, the Missouri and Ohio, during the years 1910–26. On the upper Mississippi the reservoirs at the headwaters numbered six, namely Winnibigoshish, Leech, Pokegama, Sandy and Gull lakes and Pine river, which have a combined storage capacity of nearly 95,000,000,000 cubic feet. Between St. Paul and Minneapolis the original plan for two low dams has been changed to one high dam (36 ft.) with provision for water-power development. The project was in 1925 practically completed, and the power development was leased to Henry Ford for a large assembling plant now in operation.

On the main upper Mississippi river the plan is to obtain a six-foot depth by contracting the width by brush and stone wing dams, by closing chutes and by revetting banks where necessary, supplemented by dredging. Special treatment by locks and dams is given to two localities—Rock Island Rapids and Des Moines Rapids. At the former point a lock and lateral canal at Leclaire, Ia., overcomes the fall of the Upper Rapids, and a lock and lateral canal at Moline, Ill., overcomes the fall of the Lower Rapids. The project at this point is practically completed. The open channel through both rapids is still maintained. At Des Moines Rapids (Keokuk) private interests have built a water-power dam, concentrating the entire fall of the former canal and locks into a single lock. The project is completed. There is little navigation on the upper Mississippi, but prospects for revival appear encouraging. On the middle Mississippi between the Missouri and the Ohio, the plan is for six-ft. depth above St. Louis and eight ft. below, obtained by contraction and by closing chutes with permeable pile dikes, and by revetting banks where necessary, supplemented by dredging. In that part of the river below St. Louis there is considerable revival of navigation. On the lower Mississippi river, from the Ohio river to the Passes, the plan is for nine-ft. depth, to be obtained by revetting banks, supplemented by dredging.

In 1917 Congress passed the Flood Control Act providing a certain amount of money to be expended by the Mississippi River Commission for improving the river between Cairo and Head of the Passes, and for flood control between Rock Island and the Passes. In 1923 a second Flood Control Act extended the commission's jurisdiction to all tributaries between Rock Island and the Passes, in so far as they are affected by floods in the Mississippi river. As regards the Passes, or mouths of the river, the plans adopted in 1902 having proved inadequate, additional works were authorised in 1916, which have secured a channel through southwest Pass with a controlling depth of not less than 35 feet. The controlling depth in South Pass is approximately 34 feet.

The Missouri.—On the part of the river above Kansas City there is no definite depth to be attained, the project being simply to remove snags and boulders, leaving the natural depth and width of channel, and to revet the banks at certain localities where encroachment threatens great damage. On this part of the river there was in 1926 little commerce. On the section of the river below Kansas City, there is a definite six-ft. project, adopted by Congress in 1910 and being regularly carried out. Here too there was little navigation, but prospects for revival were encouraging.

The Ohio.—A comprehensive project for canalising the Ohio so as to provide a channel nine ft. deep was adopted by Congress in 1910. Slight modifications have since been authorised. As it stood in 1926, the project provides for 50 locks and dams, all of the movable type, except the one immediately below Pittsburg, Pa., which is a fixed dam, completed in 1921, for the purpose of improving conditions in Pittsburg harbour. Of these dams 42 were completed and in operation, and the other eight were under construction, with the probability that the project will be entirely completed by 1929. The type of dam, together with the relatively low head, does not lend itself to the development of power on a commercial scale. There is one exception to this general statement, at Louisville where the existing navigation dam is being replaced by a power navigation dam eight ft. higher, thereby creating a head of 37 feet.

The total tonnage shipped *via* the Ohio river in 1924 was 10,867,000 tons of which 54% was coal. Commerce on the river has been increasing steadily, particularly on the completed part and many terminals for handling coal have been constructed. A destructive flood occurred in March 1913, and, on that part of the river between Wheeling and Cincinnati and on the tributaries entering from the north in this reach of the river, higher flood stages were reached than had been recorded prior to that date. The flood was particularly destructive in the Miami valley, and, to guard against a recurrence, extensive flood-control works have since been constructed. (H. T.*)

MISSOURI (*see* 18.607).—Since 1910 Missouri continued her transition from the period of frontier influences, of rapid growth of population and development of natural resources, to the stage of industrial development and growth of urban population. In 1925, however, the interests of the state were still primarily agricultural. The total population in 1920 was 3,404,055 as compared with 3,293,335 in 1910, an increase of 110,720, or 3·4%. The percentage of urban population (in centres of 2,500 or more) increased from 42·5% in 1910 to 46·6% in 1920. The total population in 1926 was estimated by the U.S. Bureau of the Census at 3,498,143. Of the total urban population 79·7% in 1920 was in the three cities of St. Louis, Kansas City and St. Joseph. The rural population showed an absolute decrease in both 1910 and 1920. The population of the six chief cities was as follows:—

Cities	1920	1910	Increase %	Estimate 1925
St. Louis	772,897	687,029	12·5	821,548
Kansas City	324,410	248,381	30·6	367,481
St. Joseph	77,939	77,403	0·7	78,342
Springfield	39,631	35,201	12·6	42,140
Joplin	29,902	32,073	−6·8	
Sedalia	21,144	17,822	18·6	22,745

Agriculture.—In 1924, 32,637,043 ac., or 79·1% of the total area of the state, was in farm lands. The average size of a farm was 125·3 acres. The number of farms operated by owners decreased during 1920–5, from 185,030 to 174,390. In 1919 cereal and hay and forage crops continued to lead. Cotton gained from 96,527 ac. in 1909 to 110,027 ac. in 1919 and 475,729 in 1925. Fruit, primarily apples, continued an important crop. After 1909 the acreage in Indian corn decreased to 5,567,079 ac. in 1919, and 5,479,379 in 1924, while the acreage in wheat decreased from 4,564,990 ac. in 1919 to 1,441,071 ac. in 1924. The total value of all farm crops in 1924 was $351,017,000. Indian corn was valued at $163,768,000, wheat at $32,756,000 and oats at $21,290,000. Increasing progress is ensured by the extensive drainage operation in the southeast, and by the increased interests in improved farming methods and in co-operative organisations. The Agricultural College of the state university in co-operation with the Federal Govt. has been very active in agricultural extension work; on Jan. 1 1926 farm-agent work was established in 64 counties. On Jan 1 1925 there were on the farms 714,154 horses, 390,046 mules, 1,657,682 beef cattle, 788,311 dairy cattle, 1,181,000 sheep and 3,584,399 swine.

Mines and Quarries.—The slight increase from 1909 to 1919 in the value of these products of only 5·4% to a total of $33,365,694 was due largely to the post-War depression of the latter year, when it was little more than one-third of the production of 1917, the peak of the War-time stimulation. Lead and zinc continued to be the leading products, of a value of $15,879,177 in 1919, giving Missouri second rank among the states in its production. She ranked third in clay products, with a value of $1,420,585, and second in barytes ($527,817). The other important products were coal ($12,077,845) and limestone ($2,355,736). Since 1923 there has been a marked recovery both in amount produced and in value of mine and quarry products, especially in lead and zinc.

Manufactures.—In 1921 the total value of manufactured products was $1,162,006,299, whereas in 1923 the figures were $1,547,167,429, representing an increase of 33·1%. Sixteen industries in 1923 had a product valued at more than $30,000,000 each. Slaughtering and meat-packing continued to furnish the largest single item—$152,916,678 of the total; motor vehicles were second with $137,447,034; boots and shoes third with $121,830,354. Other important industries were foundries and machine shops $44,086,595, railway cars $38,191,307 and bread and bakery products $40,888,216. The two cities of St. Louis and Kansas City gave employment to over half the wage-earners and produced two-thirds of the total values of the state, St. Louis contributing over half the latter item.

Government.—The movements to adjust the conservative constitution of 1875 to the problems of a modern state were the chief developments. Of 42 constitutional amendments submitted 1910–8, only one, permitting pensions for the blind, was adopted. The opposition to state prohibition (defeated in 1910, 1916 and 1918), and to the single tax (defeated in 1912 and 1918), contributed to the distrust of all amendments. But in 1920 nine amendments out of 13 proposed were adopted, including a provision for a constitutional convention; in 1921 all the three proposed, including the soldier bonus of $15,000,000, in 1922 two out of three, and in 1924 one of four, were adopted.

The executive department was expanded by legislation by the creation of a Food and Drug Commissioner, 1909, a Public Service Commission, 1913, a State Highway Dept., 1917 and a Tax Commission, 1917. The Public Service Commission with real powers of regulation marked a departure from the earlier Missouri practice of leaving the regulation of public utilities to local city boards. Consolidation of executive departments, urged by Gov. Hadley and begun in 1917, was enacted on a comprehensive scale, including a Budget Dept. in 1921, but all the laws were defeated by referendum in 1922.

Constitutional Convention.—The Convention, approved by popular vote in 1921, and elected on a bi-partisan basis in 1922, was in session 266 days between May 15 1922 and Oct. 5 1923. It formulated and submitted to a special election on Feb. 26 1924, 21 constitutional amendments, embodying a comprehensive revision of the constitution. All the more important proposals were rejected by the people. Of the seven amendments adopted, all but one dealt with very minor or special problems. This one was a revision of the Article on the Legislative Dept.; the main changes were the division of the state into senatorial districts by the governor, secretary of state, attorney-general, auditor and treasurer, instead of by the General Assembly; increase of pay of state legislators; authorisation of the pensioning of mothers, and (by cities) of disabled firemen and policemen, and of a workingmen's compensation law. Missouri ratified the Sixteenth Amendment to the Federal Constitution (income tax) in 1909, the Seventeenth (direct election of U.S. Senators) in 1911, the Eighteenth (Prohibition) and the Nineteenth (woman suffrage) in 1919. Missouri remained conservative in social legislation; and a workmen's compensation law in 1920 and 1921 was defeated by the referendum. It was again defeated when proposed by the initiative in 1924. A fairly comprehensive but very moderate Act was passed in 1913 for the health and safety of employees, including limitation of hours for women. The compulsory school-attendance law of 1919 incidentally limited child labour.

Revenue.—The revenue, inelastic through constitutional limitations, proved increasingly inadequate after 1910, until the unpaid current obligations in 1917 totalled over $2,000,000. Attempts to secure relief for special purposes such as schools and good roads by constitutional amendments had all failed. The Assembly of 1917 passed new indirect taxes, a state income tax, a corporation franchise tax, a direct inheritance tax, "soft" drinks stamps and wholesale liquor dealers' licences, which yielded together nearly $2,400,000 in 1917–9. To secure reater uniformity in taxation and increased revenue the basis f assessed valuation was raised in 1921 to a (nominal) 100% f actual value.

Education.—Missouri appropriates one-third of the general evenue to the support of public schools, amounting to $1,618,- 41 in 1910 and $3,219,163.35 in 1925. To this must be added 187,040, the interest on the state's common school fund of 3,159,000. The estimated total expenditure for public schools rom state and local sources rose (1910–25) from $13,905,188 to 48,760,059. The permanent county, municipal and township chool funds increased from $9,825,991 in 1910 to $12,720,879 in 925. The average daily attendance at the public schools rose rom 490,374 in 1910 to 595,305 in 1925. Although the public chools continued to lack sufficient revenue, there was much onstructive legislation, especially as to the rural schools. dditional aid was given to rural schools (1909, 1911, 1915) and high schools (1913) in the poorer districts. The requirements r teachers' certificates was raised in 1911 and 1921, and pro- ision made for the training of teachers in the high school (1913). n effective compulsory attendance law was passed in 1919. he enrolment in the state university at Columbia and Rolla creased from 3,083 (165 at the School of Mines at Rolla) in 911 to 5,604 (506 at Rolla) in 1925. An Extension Division as organised in 1913; and a School of Commerce in 1914, which as expanded in 1916 to include Public Administration.

Roads.—The state highway system dates from the Hawes Act 917), passed to take advantage of Federal aid, and the Centen- ial Road Act (1921). The latter outlined the system and pro- ided for the expenditure of a $60,000,000 bond issue approved by opular vote in 1920. Automobile fees (1922) and a gasolene x (1924) provided additional funds. Of the total mileage of ,640 projected, on Jan. 1 1926, 33% had been hard-surfaced and 7½% graded preparatory to surfacing. The work completed presents an expenditure of $73,540,686.

History.—Gov. Hadley was a leading supporter of Roosevelt r the Republican nomination in 1912, though supporting Taft the election. Wilson that year received 330,746 votes, Taft 7,821, Roosevelt 124,371. In 1916 Wilson defeated Hughes by 3,693, but the Democratic candidate for governor defeated the epublican by only 2,263. In 1918, however, Folk, the Demo- atic candidate for U.S. Senator, ran 35,283 behind Spencer Rep.). The disorganisation in the local Democratic party as increased by the opposition of Senator Reed to the League of ations and, with the general national reaction, resulted in 1920 the election of a Republican state administration and a epublican majority in both Houses of the Assembly for the st time since 1870, and in a presidential majority for Harding ver Cox of 152,363. Senator Reed (Dem.) was re-elected in 22, but in the presidential election of 1924 Coolidge defeated avis by 75,733, and Baker defeated his Democratic rival for e governorship by 5,872.

Recent governors have been Herbert S. Hadley (Rep.), 09–13; Elliot W. Major (Dem.), 1913–7; Frederic D. Gardner Dem.), 1917–21; Arthur M. Hyde (Rep.), 1921–5; Sam A. aker (Rep.), 1925– (J. Vi.)

MISSOURI RIVER: *see* MISSISSIPPI RIVER.

MISTRAL, FRÉDÉRIC (1830–1914), Provençal poet (*see* .616), in 1906 published a Provençal translation of *Genesis* nd *Olivades* in 1912, a collection of Provençal poems. His emoirs appeared, under the title *Mes Origines*, in 1906. He ed at Maillane, near Marseilles, March 25 1914.

See P. Brousse, *Frédéric Mistral* (1903); E. Lefèvre, *Bibliographie istralienne* (1903); H. J. Boeken, *Frédéric Mistral* (1910); J. rochet, *Frédéric Mistral* (1910); J. Charles-Roux, *Le jubilé de Fr. istral* (1912); E. Ripert, *La versification de Frédéric Mistral* (1917); Lasserre, *Frédéric Mistral* (1918); J. Vincent, *Frédéric Mistral: sa e et son influence* (1918).

MITCHELL, PETER CHALMERS (1864–), British zoolo- st, was born at Dunfermline Nov. 23 1864, and was educated Aberdeen University, Christ Church, Oxford and at Berlin nd Leipzig. From 1888–91 he was university demonstrator in mparative anatomy at Oxford, and for the next two years was organising secretary for technical instruction to the Oxfordshire County Council. He subsequently occupied posts as lecturer in biology at Charing Cross Hospital and at the London Hospital, and was in 1903 appointed secretary to the Zoological Society of London. He also did much useful work as a member of the committees on fishery investigations and on sleeping sickness. During the World War he was attached to the Imperial General Staff and in 1918 acted as liaison officer to the War Office and to the British War Mission. He was elected F.R.S. in 1906. His publications include *Outlines of Biology* (1894), *The Biological Problem of To-day* (1896), *Thomas Henry Huxley* (1900), *The Nature of Man* (1904), *The Childhood of Animals* (1912), *Evolution and the War* (1915) and various scientific memoirs in *The Anatomical Journal*, *The Quarterly Journal of Microscopical Science*, etc.

MITCHELL, SILAS WEIR (1830–1914), American physician and author (*see* 18.618), died in Philadelphia, Pa., Jan. 4 1914. After 1910 he published *John Sherwood, Iron Master* (1911), *Westways* (1913) and *Complete Poems* (1914).

MODERNISM: *see* FUNDAMENTALISM.

MODJESKI, RALPH (1861–), American engineer, was born at Cracow, Poland, Jan 27 1861, his mother being the actress, Helena Modjeska. He graduated at the École des Ponts et Chaussées, Paris, with high honours, and settled in the United States. From 1892 he practised as consulting bridge engineer at Chicago and as a designer and builder of bridges he did distinguished work. Among his best known bridges are the Govt. bridge over the Mississippi at Rock Island; the McKinley bridge at St. Louis; the bridges over the Mississippi at Thebes, Ill., and at Memphis, Tenn.; the Northern Pacific bridge over the Missouri at Bismarck, N.D.; also bridges over the Columbia and Willamette rivers in Oregon. He was a member of the Quebec Bridge Commission, and consulting engineer for the Ohio river bridge at Metropolis, Ill., for the Chicago, Burlington and Quincy Railroad, and the Thames river bridge at New Haven, Conn., for the New York, New Haven and Hartford Railroad. He was chosen chief engineer and chairman of the board of engineers on the Philadelphia-Camden bridge over the Delaware river, which, on its completion, in 1926, was the longest suspension bridge in the world.

MOHAMMEDANISM: *see* CALIPHATE; MAHOMMEDANISM; PAN-ISLAMISM.

MOHN, HENRIK (1835–1916), Norwegian meteorologist, was born at Bergen May 15 1835, and was educated at the Cathedral School in that town and at the University of Christiania (Oslo). In 1861 he became observer at Christiania University, where in 1866 he was elected professor of meteorology and from 1866–1913 was director of the Norwegian meteorological institute which he had been largely instrumental in founding. He carried out much valuable meteorological work, collaborating in 1876–8 with the mathematician Guldberg in a study of the dynamics of the atmosphere and subsequently extending his investigations to the subject of storms, the meteorology and oceanography of the northern Atlantic, the climate of Norway, and use of the hypsometer. Mohn also worked out and published the meteorological observations of various polar expeditions, including those of Nansen and Amundsen. He died at Christiania Sept. 12 1916.

MOLESWORTH, MARY LOUISA (1839–1921), British writer (*see* 18.660), died in London July 20 1921.

MOLNÁR, FERENCZ (1878–), Hungarian dramatist, was born Jan. 12 1878 in Budapest. After studying in that city and at Geneva, he entered journalism and attracted notice by writing short stories, novels and some brilliant farces. His best novel is *The Pál-street Boys* in which child life is portrayed with much humour and power of characterisation. His chief *métier*, however, was the drama. His first successful play, *The Devil* (1907), was exported and, produced in Turin by Zacconi, led to a great demand abroad for modern Hungarian plays. The principal features of Molnár's dramatic works are a keen romantic sense of composition, brilliant technique and a witty and satirical representation of humble life. During the World

War Molnâr was a prominent war correspondent of the Central Powers. His plays include *Liliom* (1910); *The Lifeguardsman* (1911); *Carneval* (1917).

MOLTKE, HELMUTH VON (1848–1916), German soldier, was born in Gersdorf, Mecklenburg, May 23 1848, being the nephew of the famous Count von Moltke (*see* 18.677). From 1902 to 1904 he commanded the 1st Div. of the Guards Corps and in 1906 became chief of the general staff of the army. At the beginning of the World War he was the principal director of the German operations, and it is now known that his plans were based principally on the teachings of his predecessor, General von Schlieffen. His modifications of the latter's plans seem to have been, on the whole, unwise, and on him has been placed the responsibility for the German defeat at the battle of the Marne. On Nov. 3 1914 his health being seriously impaired, he was relieved of his post to make way for General von Falkenhayn and was appointed chief of the home general staff in Berlin. He died suddenly, during a function in the Reichstag building, Berlin, June 18 1916. The following works by him were published after his death: *Erinnerungen, Briefe, Dokumente, 1877–1916* (1922), *Aufzeichnungen, Briefe, Schriften, Reden* (1923).

MOMBASA (*see* 18.682), the chief port of Kenya Colony, East Africa, had a population (1921) of 36,846, of whom 656 were Europeans and 7,574 British Indians. In 1924 the population had increased to 42,000 (821 Europeans). Mombasa harbour takes vessels up to 30 ft. draft, but is used mainly by coasting steamers and dhows; the principal harbour is Kilindini, at the southwest end of Mombasa island.

Spacious and land-locked Kilindini accommodates vessels of any size and takes all the traffic of the Uganda railway. A deep-water wharf with two berths provided with all facilities for loading and unloading, built by the Government at a cost of over £1,000,000, was completed in 1926. Much of the cargo had still, however, to be handled by lighters and the administration acquired large areas for development purposes. Steamers entering Kilindini in 1924 numbered 372 (226 British); over 1,400 sailing vessels, mostly Arab dhows, entered Mombasa harbour. See *The East African Red Book* (Nairobi, 1925).

MONACO (*see* 18.684), had a population in 1913 of 22,956. In 1911 Prince Albert of Monaco granted the principality a constitution, providing for a national council of 21 members, elected for four years by universal suffrage and *scrutin de liste*. Government is in the hands of a Ministry assisted by a council of state, acting under the authority of the prince; and legislative power rests with the prince and the national council. The territory of Monaco, which has an area of 8 sq. m., is divided into three communes: Monaco, La Condamine and Monte Carlo, each of which is administered by a municipal authority. On June 26 1922 Prince Louis II. (b. 1870) succeeded his father, Albert, as Prince of Monaco.

The principality exports olive oil, citrons, oranges and perfumes, importing in exchange coal and wine. The principal part of its revenue still comes, however, from the gaming tables. In 1917 £80,000 was paid to the Govt. by the concessionaires; and a scale was arranged providing for the payment of £90,000 in 1927 and £100,000 in 1937.

MONASH, SIR JOHN (1865–), Australian soldier, was born in Melbourne June 27 1865, and educated at Scotch College and Melbourne University. He graduated in arts, engineering and law, and became a successful engineer. He was also interested, as a volunteer, in military work, and at the outbreak of the World War held the rank of colonel. He went to the front in command of the 4th Bde. of the A.I.F.; took part in the landing at Gallipoli on April 25 1915, being thrice mentioned in dispatches; and after the evacuation on Dec. 19 1915, served in the Suez Canal zone till April 1916. He was then given a brigade in France and commanded the 3rd Div. which fought at Messines and Passchendaele. In May 1918 he succeeded Sir William Birdwood as commander of the Australian Army Corps. Although not a professional soldier, he showed a thorough grasp of the principles of the new warfare, and by his brilliant leadership materially contributed to the failure and final collapse of the German offensive of 1918. This campaign he lucidly describe in *The Australian Victoriesin France, 1918.* He was mad K.C.B. in 1918 and after the War became manager of Victoria Morwell electricity scheme.

MOND, SIR ALFRED MORITZ (1868–), British politicia was born at Farnworth, near Widnes, Lancs., Oct. 23 1868, th son of the famous chemist Ludwig Mond (*see* 18.693). He wa educated at Cheltenham and St. John's College, Cambridg and afterwards at Edinburgh University. In 1894 he was calle to the Bar, and afterwards joined the North Wales and Chest circuit. He entered the firm of Brunner, Mond and Co., becom ing a director in 1895, and also became chairman of the Mon Nickel Co. and a director of the South Staffordshire Mond Ga Co. and various other companies. He was elected to Parliamen in 1906 as Liberal member for Chester, losing his seat in 191 but the same year was elected for Swansea and created a barone In 1913 he was sworn of the privy council. On the formation Mr. Lloyd George's Ministry in 1916 Sir Alfred Mond becam First Commissioner of Works, and in 1921 Minister of Healt He lost his seat at the general election of 1923, but was returne for Carmarthen in Oct. 1924. In Jan. 1926, owing to his pr found disagreement with the principles embodied in Mr. Lloy George's land policy, Sir Alfred Mond seceded from the Liber party and declared his intention of transferring his allegiance t the Conservative party. He published many articles on th alkali trade in scientific and economic journals, besides a volum of essays, *Questions of To-day and To-morrow* (1912).

MONEY MARKET (*see* 17.732).—In no direction were the e fects of the World War more striking or far reaching than i the London money market: the great increase in banking d posits, partly as the result of inflation, was but one of the man effects produced by the War upon its dimensions, machinery an general status. Even at the end of 1925 the market was still in transition state, though in such matters as the size of the floatin debt and the value of sterling as related to New York currenc there were not wanting signs of a return to more normal con ditions.

It has always been regarded as an essential point in the Londo money market that the Bank of England, while constitutin the centre and pivot of the system, should remain a private an independent central institution without State control. In prin ciple, that position was still maintained in 1925, but there wer many influences operating during the War which at times mad the distinction between a state bank and a private central ban somewhat difficult to determine. The introduction of currenc notes, the great size of the floating debt, the growth in the Na tional Debt, and, not least, the fact that shortly after the out break of war the State, through the Bank of England, discounte practically all foreign commercial bills in Lombard Street "with out recourse," were all developments tending in that direction as leading to a domination of the money market by the Stat owing to the magnitude of its financial operations. Some ide of the closeness of relations between the State and the Ban during the War and post-War periods may be gathered from th fact that on more than one occasion the Chancellor of the Ex chequer was asked questions in Parliament relating to Ban Rate policy, as though that policy had been inspired by th Government rather than by the Bank Court. On each occasio the Chancellor very definitely disclaimed such responsibility but it was none the less recognised that of necessity the connection between the Treasury and the Bank of England was more intimate than it had been before 1914.

Following the virtual disappearance of the commercial bil during the war period came the huge flotations of Governmen Treasury Bills. The effect of this was to make Governmen operations still further dominate the course of the money marke at the expense of the normal power of the Bank of England. The potential power to create credit through borrowings o "Ways and Means" was among the factors which, during th War, gave the Government almost complete control over the money market, and which in the post-War period greatly retarded its return to normal conditions. The *de facto* abandonmen f the gold standard at the beginning of the War and the unre- tricted issue of currency notes were further circumstances ma- erially affecting the London money market, particularly the ower of the Bank to exert its normal control over the situation hrough movements in Bank Rate. With the inflation of the urrency the Bank Rate lost its power to attract gold, and the xchanges fluctuated widely.

Market Conditions.—While no actual change took place during he period 1910 to 1925 in the general construction of the money arket, and while the Bank of England continued to be the ivot of the monetary system, there were many important espects in which the money market was still abnormal at the nd of 1925. In at least three important respects money market onditions were wholly abnormal when compared with the pre- Var period. In the first place, the volume of commercial bills Lombard Street was small as compared with the pre-War eriod. This was only partly due to trade depression, for the isarrangement of international credit machinery by the War, e fact that for many years international commercial transac- ons were conducted more or less on a cash basis, and, in smaller easure, the growth of the New York money market, were also sponsible.

In the second place, there existed an outstanding volume Treasury Bills to the amount of about £635,000,000 as mpared with a standing total in the pre-War days of under 0,000,000. This huge volume of Government floating debt, gether with the annual service of the National Debt, which proached £400,000,000 (including the sinking fund) as com- red with the pre-War figures of about £23,000,000 and the eatly increased national expenditure, which was about £800,- 0,000 as compared with £200,000,000 previous to the War, ercised a dominating influence upon the course of the money arket. This, in its turn, brought the State and the Bank of ngland into still closer relation, and heavy borrowing by the overnment at certain periods of the year to pay interest on bt increased the difficulty of making the Bank Rate effective. the third place, although Great Britain had returned to the ld standard, there was, in addition to the Bank of England te circulation regulated by the Act of 1844, a Government rrency note issue to the extent of about £300,000,000, of which ly a small part was covered by Bank of England notes, which ercised a disturbing influence upon the normal relations be- een the Bank of England and the outside money market.

THE POSITION OF LONDON

Previous to the War London held unchallenged the position both the leading monetary centre and of the world's banker. Three- urths of international bills of exchange were drawn upon Lon- n, but, by reason of Britain's wealth and the supremacy of r banking system, London was the centre in which foreign untries raised their permanent loans. As a result of the War ese conditions were greatly modified, and for the time being nerica may be said to have challenged London's position of ief lender to foreign countries. During the War dealings in ls of exchange were almost suspended, international transac- ns being effected on a cash basis through the foreign exchanges, d, with New York as the one free gold centre during the War, ere was a tendency for international transactions to take dollar her than sterling form. Also, by reason of the favourable de balance obtained during the War years, her gold accumu- ions and her improved banking system, the United States t only became independent of banking aid from London, but, h the return to more normal conditions after the War, be- me the country with the largest margin of surplus resources ailable for foreign investment.

Nevertheless, it was the London money market which took e lead, under the auspices of the League of Nations, in financ- the reconstruction of certain of the Central European States. th a view to maintaining the level of sterling exchange, how- er, a semi-official restriction was placed for a period upon itish loans to foreign countries, and it was not until the end 1925 that the embargo on foreign loans was completely removed. It was, however, more in the direction of long-dated loans than in general money market facilities that relations between London and other centres were temporarily modified; and, while there was a great reduction in bills of exchange dealt in in Lombard street, foreign exchange dealings, which assumed colossal dimensions in the post-War period, tended to centre in London.

Relations with other Money Markets.—A further circumstance, however, which materially affected the relations of the London money market with other centres, and more especially with European centres, was the chaotic condition in many of the European countries after the War. This naturally disturbed the whole international credit system throughout Europe, of which London may be said to have been the centre. Not only, however, were there indications at the end of 1925 of an increase in the general volume of European international trade, but it was also clear that the London money market was holding its old premier position in financing such operations. It should also be noted that, in unison with New York, London was responsible for reconstructing and setting in motion once again the banking and financial machinery at other European centres, notably in Germany and Austria.

RESULTS OF THE WORLD WAR

In considering the conditions under which the money market was working after the end of the World War, the changed economic position of Great Britain in relation to other nations, and especially in relation to the United States, must be borne in mind. With a large visible adverse trade balance, with huge gold accumulations in the United States, with an improved banking system in America as compared with the pre-War period, and with America as a large lender to other countries, it had yet to be demonstrated how far and how quickly the London money market would be able to resume its position, not only as the leading monetary centre but as the centre most able to control the foreign exchanges by movements in the Bank Rate. Viewed from the standpoint of actual figures as measured by the wealth of America and of Great Britain, and measured also by the general movements of trade, the task seemed to be an impossible one. Measured, however, by the actual progress made by Great Britain during the post-War period, in spite of the enormous strain suffered, the problem wore a more hopeful aspect. Great Britain is still in the position of one of the largest, if not the largest, holders of foreign securities, while her shipping and financial activities contribute powerfully to her invisible exports. By general consent a great step forward towards a return to normal conditions in the money market was achieved by the return to the gold standard in 1925; but much depended upon whether, in addition to the activities of the London money market and Lombard street, the industrial activities of the country were so organised and arranged as to enable Great Britain to hold the position in international trade which she had occupied before the War and upon which the prosperity of the money market was largely based.

The Discount Houses.—The discount houses and the bill brokers remained a very important part of the money market, though their business, especially as regards the discount houses themselves, was somewhat less strictly confined to bills even before the outbreak of the World War. The deposit business of the discount houses grew materially in the post-War years, and in the matter of fixed deposits they competed somewhat keenly with the banks, upon whom, however, they were still largely dependent for regular weekly loans. During the period of the War, and as a consequence of the virtual disappearance of the ordinary commercial and bank bills, the business of the discount houses and bill brokers may be said to have been confined to Treasury Bills, and, owing to that fact and the abandonment for some years of the gold standard the expert knowledge both of bills and of international financial conditions was probably less required than at any time in the history of the London money market. With the gradual diminution of the volume of Treasury Bills, the growth in the supply of commercial bills and the return to the gold standard, the need for this expert knowledge reasserted itself, and there was little doubt that in the future the discount market would continue to exercise its old and important functions in the London money market. This, indeed, was the more probable by reason of the fact that, in spite of the improvement in the banking system in the United States, the discount market at New York had not assumed any great importance.

Meanwhile, however, owing to the fact that the growth in the volume of commercial bills had not been commensurate with the decline in the supply of Treasury Bills, the London discount market earned no small amount of its profits by jobbing in short-term Government securities on the Stock Exchange. Moreover, the fact that the joint stock banks during 1924 and 1925 charged the bill market for weekly loans at a level of 1% below Bank Rate, whereas for many years the custom was to make the charge 1½% below Bank Rate, somewhat adversely affected the discount houses and bill brokers. In one respect, conditions in the discount market had not altered greatly from the pre-War period, namely in the dependence of the market, and especially of the bill brokers, upon the Bank of England for assistance at the end of each half-year. On these occasions the joint stock banks call in heavily their short loans from the discount market, and, in connection with what has been described as half-yearly window dressing in the shape of the half-yearly and annual balance sheets, it has become customary for the discount market to have to borrow from the Bank of England during the closing days of each half-year something like £30,000,000. The loans are usually for a period of a week to 10 days, and are almost invariably repaid within the prescribed period (*see* also BANKING; CURRENCY; STOCK EXCHANGE).

MONGOLIA (*see* 18.711).—In inner Mongolia the most important political development is the Japanese claim to the eastern section as part of her sphere of influence. The history of Outer Mongolia, however, has been extremely chequered. In the main, there have been, as for a number of years past, three factors at work: Mongol restlessness under foreign control, and China and Russia. Both of the latter, no matter what their Government, have persisted in an ambition to control the country.

At the time of the revolution in China, in 1911, there was a growing unrest among the Mongol princes against San-to, the Manchu Amban at Urga, for the latter had adopted a vigorous policy of resisting Russian influence and of increasing the power of China through the promotion of Chinese immigration and trade and the strengthening of Chinese garrisons. The Mongol princes therefore took advantage of the disorder occasioned in China by the overthrow of the monarchy to oust the Amban and his subordinate (Dec. 1911), to declare their independence, and to set up the Urga Hutukhtu (Living Buddha) as their ruler. This gave Russia her opportunity, and on Nov. 3 1912 an agreement was signed between the Tsar's Govt. and that in Urga, whereby the former pledged its assistance in maintaining the independence of the latter, and the privileges of Russians in Mongolia were confirmed and extended. China naturally was dissatisfied with this arrangement, and negotiations followed between China and Russia. These resulted, Nov. 5 1913, in an exchange of notes whereby China recognised Mongolian autonomy and Russia recognised Chinese suzerainty over Mongolia. On June 7 1915, after nine months of negotiations, there was signed at Kiakhta a tripartite agreement between Russia, China and the Urga Government. By the terms of this agreement Chinese suzerainty was to be represented at Urga by a resident-general with deputies at three other places, but Outer Mongolia was to remain autonomous under the virtual protectorate of Russia.

Upon the collapse of the old régime in Russia the Chinese took steps to increase their power in Mongolia, and in 1919 Hsu Shu-tseng (" Little Hsu," assassinated Dec. 1925) was appoint " Defence Commissioner." He arrived in Urga in Oct. 19 and within a few weeks coerced the Mongols into a cancellati of their autonomy. The tyranny of his rule, however, creat unrest. Hsu lost his position after the overthrow at Peking of t clique to which he belonged, the Anfu Club, in the summer 1920, but the feeling against the Chinese continued, and af one unsuccessful attempt in Oct. 1920 Baron Ungern von Ste berg, leading a force made up of several nationalities and profe ing bitter antagonism to the " Reds " of Russia, early in F 1921 drove the Chinese out of Urga. The Living Buddha n returned to Urga, and an independent Mongol Govt. was p claimed with the Hutukhtu as ruler and Ungern as chief milita adviser. Ungern, who was probably mentally unbalanced, w extremely cruel to his enemies, and it is not surprising that was defeated by Red forces, suffered from a revolt of his troo was captured by Mongols (Aug. 1921) and executed by t Soviet authorities. Red troops now organised a government Urga, and although the Living Buddha (died May 20 1924) w acknowledged as spiritual chief, and Russia technically recognis the new government as independent, Soviet troops remained Urga. A treaty of Nov. 5 1921 provided for Russian influen The Chinese naturally objected to this renewal of Mongoli independence under Russian " protection," and the situati became an obstacle in the negotiations between China and t Soviet Government. In the agreement between China and Russ signed May 31 1924, Russia recognised Outer Mongolia as integral part of China and agreed to withdraw her troops. 1925 the Soviet Govt. announced that the withdrawal had be completed, but the influence of Russia was still far greater th that of China. (*See* CHINA.)

MONGOLIA, PALAEONTOLOGIC DISCOVERIES IN (*see* 20.579 —An important new chapter in palaeontology and geology, in t life history of the earth, has been opened by the discoveries the Mongolian expeditions of the American Museum of Natur History under the leadership of Roy Chapman Andrews. T most recent discoveries of 1925 reveal Man in three or four cultu levels of the Stone Age. During the year 1924 Andrews project a new five-year expedition, to be known as the Central Asiat Expeditions of the American Museum of Natural History, ad ing to the staff a botanist, an archaeologist and three expe topographers. With the full consent of the Mongol officials the Urga Govt., the Expedition of 1925 completed a su vey of outer Mongolia, extending their reconnaissance northwe in the direction of Uliassutai.

Palaeontologic Discoveries, 1922–5.—Central Asia, especiall the region east and south of Chinese Turkestan, had long remaine the *terra incognita* of geography, geology and palaeontology. 1900 the present writer predicted that this unknown regio rather than the well-known Asiatic provinces of the south, suc as the Siwalik Hills of India explored by Falconer (1831–42 would prove to be the chief centre of mammalian origin and di tribution, from which radiated waves of mammalian life to th continents of Europe and of North America. The exploratio of the American Museum of Natural History have not onl completely verified this prediction but have revealed the centr Asiatic plateau as the chief home of the terrestrial dinosauria reptiles of Cretaceous time. The epicontinental geologic colum of Mongolia, heretofore an entire blank, has been largely fille by the geologists Berkey, Morris and Granger during three sea sons of explorations, 1922–3 and 1925, and in the remainin three years of the Central Asiatic expeditions the remainin blanks may be successfully filled. The palaeontologic column as it is known in 1925, is shown in Table I.

Through these discoveries the Quaternary, the Tertiary an the Cretaceous epicontinental formations, corresponding alto gether with the unique " Han-Hai " beds of Richthofen (1877

REPTILIAN and MAMMALIAN LIFE SUCCESSION in the GOBI DESERT as discovered by the Central Asiatic Expeditions to the end of the year 1925. Left to right, first column: Four periods of mountain uplift. (1) Post-Jurassic mountains of Mongolia, forming by erosion the chief floor of the present Gobi desert; (2) probable Tertiary uplift of the mountains of northern China bordering the Gobi on the south; (3) Uplift, probably culminating in Miocene time, of the Himalaya Mountains bordering the central Asiatic plateaux on the southwest; (4) Upper Pliocene uplift of the Altai Mountains in the middle of the central Asiatic plateau. Second column: Ten Tertiary formations extending from Lower Pleistocene to Paleocene time, also five Cretaceous formations extending from Middle Cretaceous to Upper Jurassic time. Third column: Animals, reproduced to uniform scale, chiefly characteristic of each formation and life-zone, some of which are represented by complete skeletons, others by skulls, still others by highly characteristic teeth (*e.g.*, the giant sauropod *Asiatosaurus* and the theropod *Prodeinodon*).

Tsagan Nor Basin	Ondai Sair	500′	Upper Jurassic	*Protiguanodon* zone

ıd the “ Gobi Series ” of Obruchev (1892–1909), have been sub-
vided by the American Museum party into from 15 to 23 dis-
ıct geologic formations more or less rich in animal life, con-
ected with either Western Europe or North America, the Ter-
ary with a total estimated thickness of from 6,500 to 9,000 ft.
ıd the Cretaceous with an estimated thickness of 3,380 ft., as shown in Table I. This table includes results up to the end of the season of 1925, in which the most welcome discovery was abundant evidence of the Stone Age in Mongolia, below the Iron, Bronze and the Neolithic, namely, culture levels of Upper Palaeolithic (?Azilian-Campignian), of Middle Palaeolithic (?Mousterian) and of Lower Palaeolithic (?Acheulean) time. No

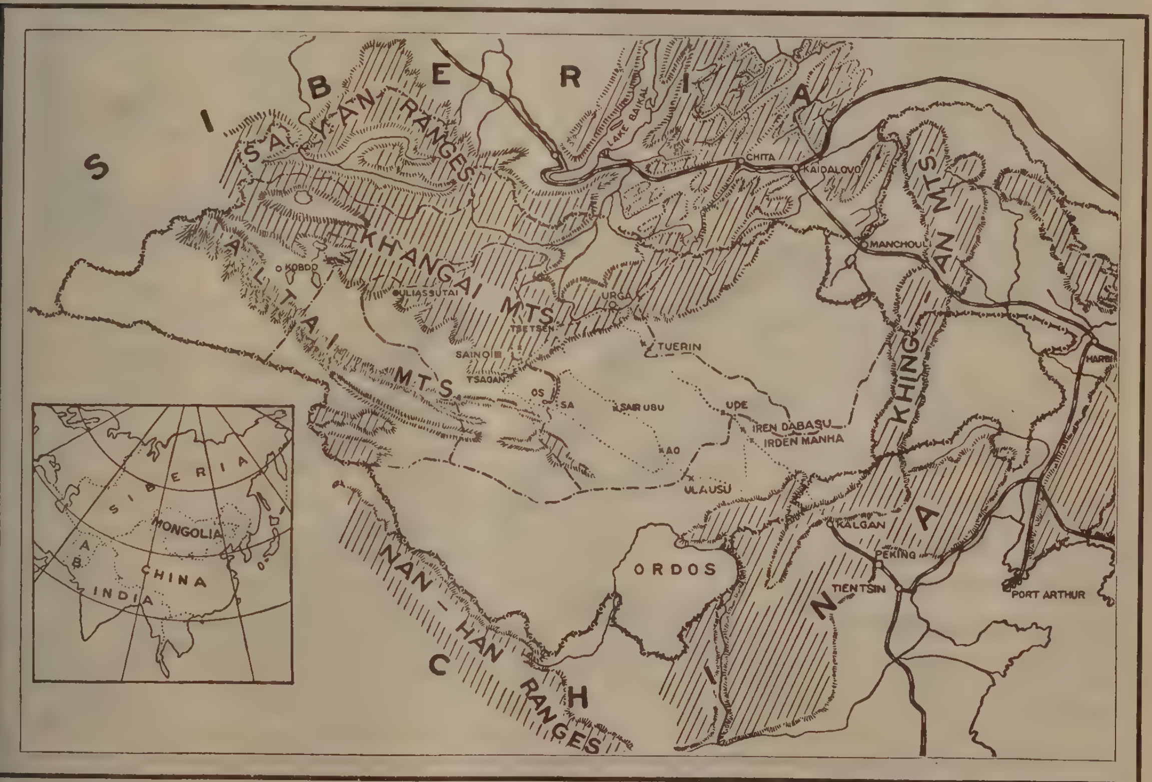

FIG. 1.—Map of Mongolia showing the routes of the Central Asiatic Expeditions of 1922–3. Slanting lines indicate mountain areas; the unshaded area is the Gobi desert.

human fossils were found; the industrial levels are not as yet precisely determinable, but the chief anthropological fact is established that Stone Age tribes spread over the southern Gobi Desert region during Pleistocene time. This accords with the prior discovery (1923) by Licent and Teilhard of the Mousterian industry in the Ordos region of China.

Equipment, Personnel and Itinerary.—It was in 1920 that R. C. Andrews first crossed the broad level Mongolian plains and conceived the plan of a camel caravan for heavy transportatio of gasolene and supplies, with light and heavy automobiles fo detour and reconnaissance work. The camel caravans, compose of from 150 to 250 animals under Mongol drivers, averaged fro 12 to 15 m. a day; the automobile trains proved capable of 10 time this speed, carrying an American party of from eight to 12 mem bers, 12 Chinese helpers and an equal number of Mongol The expedition had the advantage of speed over the work of pr vious explorers, who had entered or crossed the desert with can els only, namely, Raphael Pumpelly (1864), Ferdinand vo Richthofen (1871–2) and V. A. Obruchev (1892–1909). Th American palaeontologists and geologists, Granger, Berkey an Morris, also had the advantage of prolonged experience in th fields and geologic formations of the western United State which between the 50th and 40th parallels of latitude preser conditions remarkably similar to those in the desert of Gol (*see* map on p. 943).

In the easterly region of the Gobi desert, previously declare unfossiliferous, in which Obruchev found only a single frag mentary "rhinoceros" tooth, the expedition, leaving Kalga April 15 1922, discovered on May 3, 260 m. northwest of Kalga rich strata near Iren Dabasu of probably Lower Cretaceous ag full of large iguanodonts, megalosaurs and also ostrich-mimickin dinosaurs. Overlying this deposit (Iren Dabasu formation) we discovered much more recent Tertiary formations of Upper E cene (Arshanto and Irdin Manha formations) and Upper Olig cene (Houldjin) age, which correlate very closely with the class Upper Eocene formations of Cuvier in France and similar foss beds in Utah, Wyoming and Nebraska of the Rocky Mountai region. These Mongolian formations immediately establishe the Gobi region as a great central life zone, half-way betwee Europe and the Rocky Mountain region, according to the theor of 1900.

FIG. 3.—Sketch map of central Mongolia, showing the general geology along the routes of the Central Asiatic Expeditions of 1922, 1923, 192 the main and side routes indicated by long dashes. The arrows west of Baga Bogdo indicate northern routes along the Uliassutai Trai Finely stippled areas indicate location of chief Cretaceous and Tertiary formations listed in Table I. Hung Kureh and Gochu lie S. of Loh.

Encouraged by this brilliant initial success of 1922, the American Museum party made a 3,000-m. reconnaissance to the north as far as Urga, the capital of Mongolia, and southwest to the Altai mountains where five additional fossil horizons (Ondai Sair, Ashile, Hsanda Gol, Loh and Hung Kureh formations) of Upper Jurassic, Upper Oligocene, Miocene and Pliocene age were discovered; then southeast along the Altai mountains, where in the Djadokhta formation of Middle Cretaceous time the now famous dinosaur eggs were found, together with marvellously preserved series of dinosaur skeletons, chiefly of herbivorous types such as *Protoceratops* and of small carnivorous types. Thus the 1922–3 expeditions virtually circled the entire desert of Gobi east of the Altai mountains (fig. 1). On the return, toward Kalgan in north China, three additional Tertiary fossil horizons (Gashato, Ardyn Obo and Shara Murun) were discovered and a few representative fossils from each were brought back.

The types of dinosaurs, and of mammals which chiefly characterise these formations or horizons, are diagrammatically nown in Plate II., which displays the ancient "life zones" of Mon-olia as we descend from Lower Pleistocene into Upper Jurassic me. The animals represented in this life zone chart are known ither by complete skeletons (*e.g.*, *Protoceratops*, *Protiguanodon*, *sittacosaurus*) or by complete skulls (*e.g.*, *Baluchitherium*, *Pro-tanotherium*) or, finally, by highly characteristic teeth (*e.g.*, *siatosaurus*, *Prodeinodon*). In all of the Cretaceous horizons he correlation with Europe and with North America is provi-onal; in all the Tertiary horizons, excepting the ?Miocene Pang uang, the correlation is either absolute or fairly close.[1]

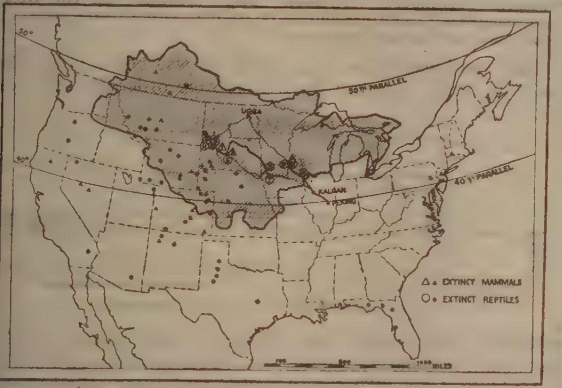

FIG. 4.—Areal map of Mongolia, projected upon map of United tates of America. Similar 50° and 40° parallels of latitude. △, ○, = hief fossil localities of central Mongolia discovered to the end of he year 1925. ▲, ●, = chief fossil localities of terrestrial dino-aurs and mammals of the United States. This map demonstrates nat the Mongolian and North American faunas occupied similar sothermal regions in central Asia and central North America from pper Jurassic to Tertiary time.

In the season of 1923 the expedition explored intensively the ossil beds visited in 1922, and returned with the camel caravan eavily loaded from the 15 or more horizons extending from he Upper Jurassic (Ondai Sair, Ashile) to the very summit of he Upper Pliocene (Hung Kureh).

These discoveries have established Mongolia as a treasure ouse of the life history of the earth from the close of Jurassic me onward to the close of Pleistocene time, *revealing especially e hitherto unknown high continental life of Cretaceous and Tertiary mes.* Consequently, the outstanding geologic discovery of the pedition is, first, that *GOBIA* (fig. 2) since Jurassic time has een a central Asiatic continent extremely favourable to the olution of reptiles, mammals, insects and plants hitherto nown only along the Cretaceous shore lines of Europe and the retaceous sea borders of the centre of America, and second, at this now terribly desert region, traversed by the gazelle and the wild ass, was certainly luxuriant with life throughout Cretaceous and Tertiary time, sparsely forested, with limited rain supply like the high plateau region of Africa to-day.

These upland conditions of Mesozoic and Caenozoic time, also favourable to the origin of the human race itself, led to the further generalisation by H. F. Osborn, on returning from Iren Dabasu in 1923, that the ancestors of man occupied this region during Caenozoic time and are likely to demonstrate the central Asiatic theory of human origin. This generalisation was partly verified during the year 1925.

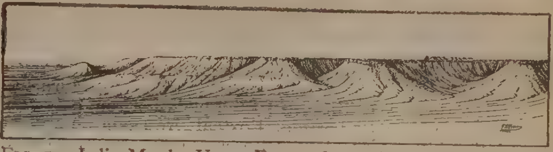

FIG. 5.—Irdin Manha Upper Eocene formation of the Iren Dabasu Basin, eastern Mongolia. Rich in titanotheres and other large mammals of American Upper Eocene affinities. (Compare fig. 3.)

TABLE II. *Human Culture, Mammalian and Reptilian Life Zones in Descending Order*

1. *Mongol graves* of early historic time.

2. *Iron and Bronze ages* represented by monuments and graves in the Gobi desert.

3. *Neolithic* represented in the upper levels of Shabarakh Usu deposits; pottery, etc., ostrich eggs (*Struthiolithus*).

4. *Uppermost Palaeolithic of Shabarakh Usu.* Indurated sands containing flints, resembling those of the ?Azilian and Campignian industries of Europe; eggshell ornaments made of *Struthiolithus* and of fossilised dinosaur eggs. The "dune-dwellers" of prolonged occupation. True Upper Palaeolithic not found.

5. *Lower Palaeolithic.* Near Orok Nor, 20 m. from Kholobolchi Nor. Flint industry of possible Aurignacian age; flints certainly of Mousterian age, of IV. Glacial and pre-Glacial time resembling those of the Ordos.

6. ?Acheulean or ?Eolithic flints of uncertain age.

7. *Tsagan Nuru, Gochu.* Regarded as base of the Pleistocene. The Gochu, 1,000 ft. in thickness, overlies the Hung Kureh at the foot of the Altai range Baga Bogdo. The sands of Tsagan Nurud contain *Equus* and *Struthiolithus.*

8. *Hung Kureh.* Lower Pleistocene and Upper *Pliocene.* Containing in lower levels, a true Upper Pliocene horizon, *Hipparion*, *?Elephas*, *Cervus*, *Castor*, *Camelus*, *Gazella*, rhinoceros, ?Coelodonta. Compare Plaisancian-Astian of France and Italy.

9. *Loh.* These gravels and clays, directly overlying the Hsanda Gol, are apparently of Middle Miocene age. Containing a mastodont, *Serridentinus mongoliensis*, and a diminutive baluchithere, *Baluchitherium mongoliense.* Compare Lower and Middle Miocene Burdigalian-Helvetian of France.

10. *Hsanda Gol.* Great formation 3,000 ft. in thickness, of Middle to Upper Oligocene, or Stampian to Aquitanian. Containing abundant remains of *Baluchitherium grangeri*, a skull having been found in 1922 and a leg and feet in 1925; small rhinoceros; very large small-mammal fauna, several thousand jaws belonging to 30 genera of rodents, creodont carnivores, true carnivores, insectivores related to *Tupaia* (the tree shrews) and *Macroscelides* (the jumping shrews). The prevailing affinities of this fauna are with the Quercy Phosphorite of France; there are also distant affinities to modern African rodents and insectivores; relationship to North American and the Middle Oligocene White River fauna is less close, except in the wide-ranging carnivores like *Hyaenodon.* The larger rhinoceros *Baluchitherium* resembles that of Baluchistan (Forster Cooper) and the *Indricotherium* (Borissiak) of Turkestan.

A formation of similar age in the Iren Dabasu basin is the *Houldjin*, where Obruchev discovered his "rhinoceros" tooth, probably a baluchithere.

Apparently intermediate between the well-determined Hsanda Gol and the Ardyn Obo formations, there were found in 1925 three other horizons in which the faunas are still to be determined, namely, *Elegen*, Middle to Upper Oligocene, *Baron Sog*, Middle Oligocene and *Ulan Gochu*, Lower Oligocene.

11. *Ardyn Obo.* 500 ft. thick. On the Uliassutai trail. Contains rich Lower Oligocene (Sannoisian) fauna, chiefly of ungulates, including giant titanotheres (*Brontops gobiensis*, *Menodus mongoliensis*) broad-skulled and long-skulled titanotheres similar to those of South Dakota and Colorado; also an amphibious rhinoceros, *Cadurcotherium* mongoliense, intermediate in character between *Cadurcotherium* of the Lower Oligocene of France and the American *Metamynodon.* The creodont carnivores include *Hyaenodon* and aberrant oxyaenids ancestral to Hsanda Gol forms. Compare Infra-Tongrian, Ronzon, Quercy.

12. *Shara Murun.* Richly fossiliferous formation on the Uliassutai trail, representing the very summit of Eocene time. Contains

---

[1] To clearly understand the above description the reader should refully examine Plate I., correlation chart, and Table II., faunal ccession.

imposing titanothere fauna (*Prototitanotherium andrewsi, P. mongoliense, Dolichorhinus*), quadrupeds extraordinarily similar to those of Utah in the Rocky Mountain region. Here occur the amphibious amynodonts, also a long-limbed rhinoceros ancestral to *Baluchitherium*, and numerous smaller odd-toed ungulates suggestive of *Tapirus* and the cursorial *Colodon* (*Deperetella*), all of strong American resemblance. Most important is the pro-ruminant *Archaeomeryx*, in all respects ancestral to the higher ruminants (*Cervidae*, etc.). The carnivores of this horizon (*Hyaenodon, Pterodon*) are again of Franco-American affinities. Compare Ludian stage of France, Gypse de Montmartre.

Tukhum is another formation discovered in 1925, which has not yet been fully studied. It directly underlies the Shara Murun.

13. *Irdin Manha.* In this great flood-plain horizon, only 100 ft. in thickness but of vast horizontal extent, we again observe very close relationships to the Upper Eocene of the Rocky Mountain region. Outstanding types are the titanotheres (*Dolichorhinus, Protitanotherium, Mesatirhinus*); the giant *Eudinoceras*, four-horned and tusked, comparable to *Dinoceras* Marsh of the Rocky mountains; finally, the giant *Andrewsarchus*, a primitive creodont carnivore named after Andrews, the leader of the Central Asiatic Expeditions.

14. *Arshanto.* A little-known formation directly underlying *Irdin Manha*, probably of Middle Eocene age, containing small lophiodonts.

15. *Kholobolchi.* In this newly discovered horizon occur animals similar to the *Coryphodon* of the Suessonian of France and the Lower Eocene Wasatch of the Rocky mountains.

16. *Gashato.* Rich fauna of Paleocene age, including *Palaeostylops*, an herbivore related to a South American genus as determined by Matthew; also the long-tusked amplypod *Prodinoceras*, ancestor to *Eudinoceras* and related to a smaller form in the Rocky Mountain region.

No horizons have been discovered representing the close of Cretaceous time but the beginning of Upper Cretaceous time is probably represented by the famous *Djadokhta* horizon containing *Protoceratops* and the nests of fossilised dinosaur eggs.

17. *Djadokhta.* These flaming red cliffs of aeolian sand apparently preserve the entire reptilian fauna of this locality, which appears to have been a nesting ground of the primitive horned dinosaur known as *Protoceratops*. The delicate red sand contains in nearly perfect condition nests of eggs varying from 12 to 20 in number, belonging chiefly to *Protoceratops*, representing at least three species or genera of dinosaurs. This primitive horned dinosaur is represented by nearly seventy growth-stages, from the tiny skeleton within the eggshell to skulls about two feet in length. Small carnivorous dinosaurs, *Velociraptor* and *Saurornithoides*, are found, also the ornithomimoid *Oviraptor*, so named because its skeleton rested directly upon a nest of dinosaur eggs. Most remarkable were small mammals of the size of mice and shrews, represented by six skulls, related to small creodont carnivores and to insectivores.

18. *Dohoin Usu.* A fossiliferous basin, the fauna of which has not yet been examined.

19. *Iren Dabasu.* A very rich horizon in eastern Mongolia containing dinosaurs of Lower Cretaceous, possibly Wealden, age; *Iguanodont* equal in size to the *Ibernissartiensis* of Belgium; also a carnivorous dinosaur, possibly resembling *Deinodon* of the American Middle Cretaceous; finally, a toothless ostrich resembling *Struthiomimus* in size.

20. *Ashile.* In the Oshih basin, containing small parrot-beaked iguanodont dinosaur known as *Psittocosaurus mongoliensis;* the giant sauropod *Asiatosaurus*, resembling *Camarasaurus* of the American Upper Jurassic Morrison horizon; and *Prodeinodon*, resembling *Allosaurus* of the Morrison of Wyoming. This fauna appears to be of sub-Wealden age and to represent the close of Upper Jurassic time.

21. *Ondai Sair.* A small parrot-beaked leaf-eating iguanodont *Protiguanodon mongoliense*, more primitive in tooth structure than *Psittocosaurus*, remotely related to Huxley's *Hypsilophodon foxi* of the Wealden of England. This horizon contains a rich insect fauna.

Bibliography.—The scientific and semipopular literature is already extensive. In *Asia Magazine*, which helped to finance the expeditions and which owns the copyright of many of the photographs, has appeared a series of narrative articles (1922–5) by the leader of the expeditions, Roy Chapman Andrews, which are being republished in his volume, *On the Trail of Ancient Man* (1926). Preliminary scientific papers by the geologists and palaeontologists of the expeditions, Messrs. Berkey, Morris, Granger, Matthew and Osborn, have appeared chiefly in the American Museum *Bulletins* and *Novitates* and are collected in a volume entitled *Preliminary Reports of the Central Asiatic Expeditions*, vol. i., which has been distributed to 100 of the chief scientific institutions of the world. More mature scientific publication is projected in a series of 12 volumes, of which vol. ii., *Geological Reconnaissance in Mongolia*, by Charles P. Berkey and Frederick K. Morris, will appear first.

(H. F. O., R. C. A.)

MONITOR.—Almost immediately on the outbreak of the World War it became apparent that the German occupation of Belgium could be to a certain extent out-flanked along the coast by bombardment of the ports which were being used as bases for torpedo boat destroyers and submarines. As the water is very shallow fo a considerable way out, it became necessary to have vesse drawing very little water, and soon after the outbreak of war th British Navy took over three river monitors, built by Messr Vickers for the Brazilian Govt., with a view to using them o the Belgian coast. These were only small vessels, renamed th " Humber," " Mersey " and " Severn," mounting 6-in. and 4·7-i guns, and it soon became evident that vessels of the monito type, with heavier guns and better protection, would be ver useful. An interesting account of how the suggestion arose t add big gun monitors to the fleet in 1914 is given by the the First Lord of the Admiralty, the Rt. Hon. Winston Churchil in his book " The World Crisis 1911–4."

At a conference with Lord Fisher and Mr. Schwab concernin submarine contracts, Mr. Schwab offered to supply to the Admiralt four turrets, each mounting two 14-in. guns, which had been almo completed for the Greek battleship " Salamis," then building i Germany for Greece. This offer was accepted, and Mr. Churchil remembering the good work done by the three small ex-Brazilia monitors " Humber," " Mersey " and " Severn " off the Belgia coast, suggested monitors should be built to carry these 14-in. gun close inshore to attack the enemy.

Thus the idea of the 14-in. monitors was born, and in Nov the four vessels to carry these guns were ordered, the " Abercrombie," " Havelock " and " Raglan " from Messrs. Harlan and Wolff, and the " Roberts " from Messrs. Swan and Hunte

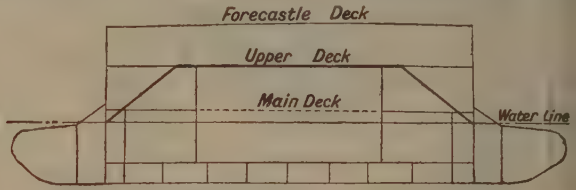

Fig. 1.—Section of a typical monitor.

Main Features.—The characteristics of these monitors wer shallow draught and very good under-water protection by mean of a complete bulge, and a typical section of a big gun monito is shown in fig. 1.

The fact that both these qualities diminished very greatl the risk of successful torpedo attack brought to the fore the great possibilities. So highly thought of, in fact, were thes possibilities that additional guns were sought to provide th armament for further vessels of this type, and this was done b using two 15-in. gun turrets, which were ready for battleship under construction, stripping the old " Majestic " class of battle ship of their 12-in. turrets and the " Powerful " and othe vessels of their 9·2-in. guns. With these guns around which t design the monitors swift progress was made.

Toward the end of 1914, eight vessels were ordered to carr the 12-in. guns, followed by further orders early in 1915 for tw vessels to carry the 15-in. guns, 14 to carry the 9·2-in. and five t carry the 6-in. guns.

The names of these various types were as follows, and th tables below give the detailed particulars:—

14-in. Monitors: " Abercrombie," " Havelock," " Raglan " an " Roberts."

12-in. Monitors: " Lord Clive," " General Crauford," " Earl o Peterborough," " Sir Thomas Picton," " Prince Eugene," " Princ Rupert," " Sir John Moore " and " General Wolfe."

15-in. Monitors: " Marshal Ney," " Marshal Soult " and two of later type, " Erebus " and " Terror."

9·2-in. Monitors: M.15 to M.28.

6-in. Monitors: M.29 to M.33.

A typical profile of a big gun monitor with a 9·2-in. gun is show in fig. 2 and the detailed particulars of the various vessels ar given in table on p. 945.

The 9·2-in. and 6-in. vessels were designed for river work an for manoeuvring in closed waters, and were not bulged.

Machinery.—In the construction of all these monitors tim was essential, and in several cases the big gun monitors wer launched within four months of the keel being laid, and completed ready for service within just over six months. It wa

Type	Length between perpendiculars	Length over-all	Breadth ext.	Load draught mean	Displacement	S.H.P. of Engines	Speed at load drght.	Fuel capacity	Armament
	ft.	ft. in.	ft.	ft.	tons		knots	tons	
14-in.	320	334-6	90	10	6,150	2,000	6–7	400 coal	2–14-in. 1–6-in.
12-in.	320	335–6	87	10	5,900	2,300–2,500	6–7	350 coal	2–12-in. 1 to 4–6-in.
15-in.	340	355–8	90¼	10¼	6,670	1,500	6–7	235 oil	2–15-in. 8–4-in.
9·2-in.	170	177–0	31	6	540	480–800	12–13	30 oil	1–9·2-in. 1–3-in.
6-in.	170	177–0	31	4	355	400	10	45 oil	2–6-in. 1–6-pdr.
"Erebus" "Terror"	380	405–0	88	11	8,000	6,000	12	750 oil	2–15-in. 8–4-in.

eccessary, therefore, to take, in many cases, whatever machinry happened to be available, and in consequence the machinery nstallations varied somewhat. The 14-in. and 12-in. monitors ll had either quadruple or triple expansion reciprocating enines, but the 15-in. vessels, "Marshal Ney" and "Marshal oult," had twin sets of internal combustion engines, originally esigned for oil carriers. All the 6-in. monitors were twin screw ith steam engines and oil-fired boilers. The oil engines in the wo 15-in. monitors were never quite satisfactory, and this, ombined with the somewhat bluff form of the boats, gave ather a poor speed on service, and after a time it was decided to uild two larger and faster vessels to carry these 15-in. guns to etter advantage. This decision was modified owing to various ther conditions which arose, and it was ultimately decided to ake out the guns from the "Marshal Ney" and to provide in ddition a new twin 15-in. mounting to complete the two sets of uns necessary for the two new vessels.

The "Erebus" and "Terror."—These vessels had special ulge protection of an improved type, and with their more powrful machinery of 6,000 H.P. and improved form had a speed of 4 knots. Ordered in Sept. 1915, and completed in 12 months, ney proved very efficient on service, and although both were eavily struck by German torpedoes, neither was seriously damged and the repairs were quickly effected.

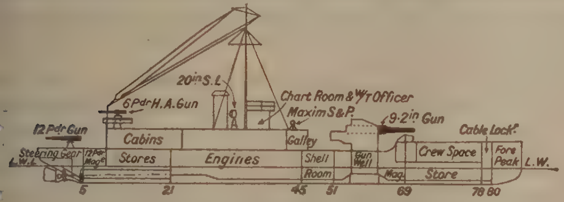

FIG. 2.—Profile section of monitor mounting a 9·2-in. gun.
From Brassey's *Naval and Shipping Annual.*

Two other vessels, although not of the true monitor type, were onverted for similar service to that on which monitors were nployed.

"Glatton" and "Gorgon."—The "Glatton" and "Gorgon" ere armed with two 9·2-in. guns and six 6-in., together with everal smaller. Originally the coast defence vessels "Bjorgrin" nd "Nidoros," building for the Norwegian Govt. by Messrs. rmstrong and Whitworth, they were finally put into commission oward the end of 1918 after the fitting of bulge protection.

The "Glatton" was unfortunately lost in Dover Harbour oon after her completion owing to an explosion on board causing n outbreak of fire. To prevent possible further explosions it was ecided to sink the vessel at anchor, and owing to the bulge proection, it took three torpedoes at close range to do this, and nese caused the vessel to sink slowly.

With the exception first mentioned of similar monitors originally designed and built for the Brazilian Govt. which were taken over by the British Govt., none of the foreign powers appear to have developed this type of vessel to any extent during the War, although the Italian Govt. mounted some heavy guns on a kind of barge, but these were much more of the nature of an improvisation than the British vessels, and there appears no question that this type of vessel is only needed for very special work in shallow waters, and no more have been built. During the Gallipoli campaign several of the monitors were sent out there and did good work in bombarding the Turkish lines at long range.

Quite at the end of the War it was decided to mount two very big guns on three of the 12-in. monitors, and an 18-in. gun was mounted on the "Lord Clive," the "General Wolfe" and the "Prince Eugene." Only two of these vessels were completed with their 18-in. mountings before the end of the War, but they fired a good many rounds of this huge projectile into the German lines in the neighbourhood of Bruges.

Of all these vessels produced during the War with such great expenditure of money and concentrated energy, only three of the big-gun type now remain on service. These are the "Erebus" and "Terror" and "Marshal Soult," all of which are the 15-in. gun type, and these are at present being used as drill ships. Of all types of warships carrying heavy calibre guns the monitors were in action far more often and for longer periods than any other type, whether battleship or battle-cruiser, and the losses, as shown below, were correspondingly heavy.

"Raglan," 14-in. type. Sunk by gunfire of the German battle-cruiser "Goeben" in action off Imbros on Jan. 20 1918.

M.15, 9·2-in. type. Torpedoed by a German submarine off Gaza on Nov. 11 1917.

M.21, 9·2-in. type. Mined off Ostend on Oct. 20 1918.

M.25, M.27, 9·2-in. type. Lost during operations on the Dvina river, north Russia, on Sept. 17 1919.

M.28, 9·2-in. type. Sunk by gunfire of the German battle-cruiser "Goeben" in action off Imbros on Jan. 20 1918.

M.30, 6-in. gun type. Sunk by Turkish batteries in the Gulf of Smyrna, on May 13 1916.

MONOD, GABRIEL (1844–1912), French historian (*see* 18.730), died at Versailles April 10 1912.

MONOPLANE: *see* AEROPLANE.

MONRO, SIR CHARLES CARMICHAEL (1860–), British soldier, was born June 15 1860, and joined the army in 1879. In 1897–8 he saw service at Malakand, in the Mohmand country, in Bajour and in Tirah and he was on the staff in South Africa (1899–1902). He was afterwards commandant of the School of Musketry at Hythe, Kent. Having commanded the 2nd Div. in the first fighting in 1914, Monro was, at the end of 1914, placed in command of the I. Army Corps, and on a III. Army being organised in July 1915, he was given charge of this. He was chosen in October to take over the command of the Mediterranean Expeditionary Force and to decide whether the campaign in the Gallipoli Peninsula was to be continued. Monro acted with rare decision. Although the Govt. was disposed to cling to the peninsula, he insisted upon its abandonment, and he was, after some delay, allowed to have his way, with the result that the forces were withdrawn from a most dangerous position without appreciable loss. He returned to the Western Front to succeed Sir Douglas Haig in command of the I. Army, but in Oct. 1916 he was selected to be commander-in-chief in India.

In his new sphere Sir Charles Monro proved himself to be a military administrator of the first rank. By untiring energy and skilful organisation he succeeded in adding substantially to the strength of the native army, in creating a number of fresh regiments and in greatly developing the non-combatant and hospital services on progressive lines. The consequence was that he was enabled to dispatch considerable and badly needed reinforcements to Mesopotamia and to Egypt and Palestine. In Sept. 1923 he was appointed to the position of governor and commander-in-chief of Gibraltar.

MONS, BATTLE OF: *see* FRONTIERS, BATTLES OF THE.

MONTAGU, EDWIN SAMUEL (1879–1924), British politician, second son of the 1st Lord Swaythling (head of the financial firm of Samuel Montagu and Co.), was born Feb. 6 1879 and educated at the City of London School and at Trinity College, Cambridge. At Cambridge he was president of the Union and acquired a considerable reputation for ability. When he entered Parliament in 1906, as Liberal member for the Chesterton division of Cambridgeshire, he was chosen by Mr. Asquith, then Chancellor of the Exchequer, as his parliamentary secretary, and continued in that position when his chief succeeded to the premiership. Early in 1910 he was appointed Under-Secretary for India, under Lord Morley, and remained in the post, under Lord Crewe till 1914; and so made his first official acquaintance with India under the influence of Lord Morley's reforms and Lord Crewe's Durbar changes of 1911. As both his chiefs were in the Lords, he was the spokesman of the office in the Commons, and he acquitted himself well. That he might equip himself the more completely for his duties, he took the unusual course of visiting India in person.

After holding during the World War the posts of Financial Secretary to the Treasury—where he had much to do with the introduction of War Savings Certificates—Chancellor of the Duchy of Lancaster (1915) and Minister of Munitions (1916), he returned in 1917 to the India Office as Secretary of State and began a tenure of that post which will always be memorable in Indian annals.

He visited India in the following winter for the second time, and held prolonged conferences with the Viceroy, Lord Chelmsford, the leading members of the Indian Civil Service, ruling princes and native politicians, and along with the Viceroy received deputations and memoranda from all classes. Ultimately in July 1918 there was published an elaborate report, signed by the Viceroy as well as by the Secretary of State, recommending a series of constitutional reforms which should give the Indian peoples a large and real share in their own government. The report was received so cordially in the House of Commons that Mr. Montagu was able to claim at the end of the debate as "a remarkable fact" that all speakers admitted the principle of self-government for India. In Dec. 1919 he had the satisfaction of passing through Parliament the Government of India bill, which established in India, in accordance with the report, what was called a "diarchy," a partition of the powers of Government between the civil service and the native population.

Unfortunately, by the time the Act was passed the situation in India had become grave. The Rowlatt Sedition bill had provoked alarm and excitement throughout the country; Mr. Gandhi had organised passive resistance; serious disorders had broken out in Delhi and other places and in the Punjab had become something like open rebellion, in the course of which there had been a tragedy on April 13 1919 at Amritsar, where General Dyer's troops in dispersing a mob had killed nearly 400 persons. Inquiry was instituted and Dyer had to retire; but much ill-feeling remained, and Mr. Gandhi started a non-co-operation movement as the new councils began to work. Mr. Montagu's policy lost its attractiveness for a large section of the House of Commons, and in the debate on the address in 1922 he was attacked on account of the unrest and crimes in India. In March he had to resign his office for having published, without the authority of the Cabinet, a telegram from the Government of India urging the advisability of pursuing, in India's interest, a more friendly policy towards Turkey. He defended his action by maintaining that Cabinet responsibility had been destroyed by Mr. Lloyd George's dictatorial methods. At the general election of 1922 he lost his seat in Parliament, and went into the City, becoming vice-chairman of the De Beers Co. He had married in 1915 Beatrice Venetia, youngest daughter of the 4th Baron Sheffield, and he died in London Nov. 15 1924.

MONTANA (*see* 18.752).—In 1920 Montana had a population of 548,889, an increase of 172,836, or 46%, during the decade. The urban population was 172,011, or 31·3%; the rural 376,878, or 68·7%. In 1910 the ratio was 35·5% urban and 64·3% rural. The relative increase of rural inhabitants over urban was c largely to the immigration of an agricultural populatic particularly to the eastern part of the state. The total numb of foreign-born whites in 1920 was 93,620. In 1920 there were cities with a population of 5,000 or more, of which six had ov 10,000. These six, with their increase in the preceding decad were as follows:—

	1920	1910	Increase
			%
Butte	41,611	39,165	6·2
Great Falls	24,121	13,948	72·9
Billings	15,100	10,031	50·5
Missoula	12,668	12,869	−1·6
Helena	12,037	12,515	−3·8
Anaconda	11,668	10,134	15·1

Agriculture and Irrigation.—In 1910 there were 26,214 farr with a total acreage of 13,545,603, of which 3,640,309 ac. we improved. In 1920 there were 57,677 farms with an acreage 35,070,656, of which 11,007,278 ac. were improved. Of the lar improved, about 4,000,000 ac. were under tillage. In 1925 t number of farms had decreased to 46,896. In 1920 abo 1,700,000 ac. were irrigated; many new projects were und way, and in 1925 nearly 2,000,000 ac. were irrigated. In 19 about 3,000,000 ac. were planted to wheat, the most importa crop, and the crop was estimated at 51,668,000 bushels. Fla hay, sugar beets, oats, beans, potatoes, corn and peas ra next in order of value, but wheat in 1924 was worth more tha all other crops combined. The total value of crops in 1924 w $144,463,000. During the period from 1910 to 1925 the op range was superseded by the fenced ranch. The number sheep declined from 5,381,000 in 1910 to 2,083,000 in 192 but increased to 2,536,000 in 1925. In 1910 there were 943,0 cattle; in 1920, 1,269,000; and in 1925, 1,505,000 (estimated In 1925 there were 220,000 milch cows, and dairying has becon an important industry. In 1910 there were 316,000 horses; 1920, 669,000; and in 1925, 593,000. All livestock in 1925 w valued at $94,000,000.

Forests.—In 1923 the national forests in Montana include 15,881,715 acres. The state owned 566,000 ac. of forest lan and there were 5,000,000 ac. in private hands. A part of th forest area is valuable also for agricultural land and will be used when the timber is removed. The remainder will be r forested as the old trees are cut.

Mines.—The World War gave a great impetus to the pro duction of copper and other metals, but after the Armistic the output declined acutely. In 1910 the production of coppe was 283,000,000 lb.; in 1916, 352,000,000 lb.; and in 192 49,000,000 pounds. Since then it has increased to 224,000,0 lb. in 1923 and to 249,000,000 lb. in 1925. In 1918 the productio of zinc was 104,624 tons; and in 1922, 59,535. The productio of lead dropped from 18,568 tons in 1918 to 11,565 tons in 192 increasing to 21,226 tons in 1924. Silver production has remaine steady at about 12,000,000 oz. per year, but gold dropped fro 158,704 oz. in 1918 to 80,145 oz. in 1922. The output of coal i 1924 was estimated at 2,700,000 net tons. In 1915 oil wa discovered in the state, and the output has steadily increase until in 1924 it was estimated at 2,781,000 barrels.

Manufactures.—The vast supplies of water-power in Montan give hopes of great industrial development. The hydroelectr plants in 1923 had a capacity of 400,000 H.P., an increase o 120,000 in three years. Much of this was used for the operatio of electric trains. The potential hydroelectric developmen is estimated at 4,000,000 horsepower. In 1920 Congress passed bill authorising the Secretary of the Interior to lease the undevel oped power-sites, and the completion of such enterprises will ad greatly to the electric power available. In 1909 the total valu of manufactures was $73,000,000; in 1923 it had increased t $174,874,000. In 1920 there were 195 lumber-mills, 75 flour-mills 31 creameries, 7 cheese factories, 2 canning factories. The mos promising field for manufacture appeared to be products o copper and wood. One plant for turning out copper rods and wire had a capacity of 6,000,000 lb. of copper per month.

Education.—In 1920 the Russell Sage Foundation of New York ranked the Montana schools first among all the public-school systems of America. The public-school fund belonging to the state amounted in 1924 to about $20,000,000, the income to nearly $1,000,000 per year. The total expenditures for schools n 1924 was $14,878,000. In 1924 there were 118,000 pupils in elementary and high schools out of a school population of 157,745. In 1912 President E. B. Craighead, of the State University, started a campaign for the consolidation of all the state institutions of higher education into one university. His plan was defeated, but all the institutions were placed under one administrative head called the chancellor.

Legislation.—The state has made steady progress in labour egislation. In 1911 the Legislature provided an eight-hour day or miners. In 1914 the state limited the working day for women n factories, laundries and stores to nine hours, and in 1917 reduced this to eight hours. In 1915 a Workmen's Compensation bill was enacted. In 1915 provision was made for state inpection and grading of grain, and a Farm Loan Act was passed. In 1917 the state provided insurance against hail for farmers. In 1911 the Legislature authorised cities to adopt the commission form of government, and in 1917 sanctioned the commission-manager plan. In 1912 the people established through he initiative a system for direct primaries to nominate all state and local officials and to express their preference for presidential andidates. They also passed a rigid Corrupt Practices Act imiting campaign expenses, providing for their publicity and orbidding electioneering on election day. In 1914 the people atified a constitutional amendment for woman suffrage. The mportant social legislation in recent years included a Mothers' Pension law; a Teachers' Retirement Pension law; and an Act to provide for the establishment and maintenance of county braries. In 1921 Gov. Dixon proposed an income tax, an ineritance tax and a tax on the production of oil wells and of coal and metal mines. The Legislature opposed these recommendaions as radical, but finally agreed to a small tax on oil and coal production. In 1924, however, the people passed an initiative measure providing for a graduated tax of from 0·25% to 1% n the gross product of metal mines. In 1923 the Legislature assed an effective inheritance tax law.

History.—Montana entered upon the second decade of the 0th century under very prosperous conditions. A new railway ad just been built across the state. Mines were operating uccessfully, and there was a growing demand for Montana umber. Great irrigation projects were under way, and in many ections of the state dry-farming was proving a success. The World War stimulated the mining and lumber industries, but t put a stop to the great reclamation works. During the later ears of the decade drought seriously hampered the dry-land armers and there was a decline in farm production. State politics have largely hinged upon matters of taxation, particulary the taxation of mines. The constitution provides that mines shall be taxed at the price paid the United States therefor," lthough the " net proceeds . . . shall be taxed as provided by w." The mining interests maintain that, since mining is a peculative business and the mines are being gradually exausted, the net proceeds should be taxed at no higher rate han real estate or personal property. Their opponents maintain hat since practically no tax is imposed on mines as such, the ax on " net proceeds " should be much higher than the property ax. The constitution limits taxes for state purposes to two mills n the dollar unless increased by special vote of the people. This as adequate during the early years of the state's history. ince 1910, however, due to greater demands upon the state overnment, this constitutional restriction has produced a serious eficit. In 1920 the deficit amounted to about $2,500,000; une 30 1924 it was $3,595,558; and June 30 1925 it was 3,817,402. In the fall of 1925 the metal mines tax provided an ncome of approximately $500,000, and through the death of V. A. Clark the inheritance tax produced about $900,000.

In 1914 Jeanette Rankin was elected representative to ongress as a Republican, the first woman to be a member of that body. During the World War the Non-Partisan League spread over the state. It started first among the farmers, but soon extended among the labour groups. In 1918 it elected a number of members of the state Legislature. In 1920 the farmers and labour men went into the Democratic primaries and nominated a former U.S. district attorney, Burton K. Wheeler, for governor. The merchants and other business interests organised the Montana Development Assn. to oppose the Non-Partisan League. This organisation supported Joseph M. Dixon, former Senator and manager of Roosevelt's campaign in 1912, for governor on the Republican ticket. The Republican platform declared for a conservative programme, and the entire Republican ticket was elected. Gov. Dixon's demands for the taxation of mines, and for other special taxes, however, lost him the support of the larger business interests. In 1924 he was defeated by John E. Erickson who announced a programme of economy and no increase in taxes.

The governors of Montana after 1910 were as follows: Edwin L. Norris (Dem.), 1909–13; Sam V. Stewart (Dem.), 1913–21; Joseph M. Dixon (Rep.), 1921–5; John E. Erickson (Dem.), 1925– .

See Helen F. Sanders, *History of Montana* (3 vol., 1913); Tom Stout, *Montana, Its Story and Biography* (3 vol., 1921); Montana Dept. of Agriculture, Labor and Industry, *The Resources and Opportunities of Montana* (9 vol., 1912–22); *Montana Farm Review* (1922–). (P. C. P.)

MONTELIUS, OSKAR (1843–1921), Swedish archaeologist, was born in Stockholm Sept. 9 1843. He studied at the University of Stockholm, and took the degree of Ph.D. in 1869. In 1888 he was appointed a professor in the Museum of National Antiquities, Stockholm, and in 1913 became state archaeologist. As an archaeologist his aim was to utilise and develop the typological method explained by him in his book *Die Typologische Methode* (1903). His numerous other works are devoted principally to Swedish and Italian archaeology and include *The Civilisation of Sweden in Heathen Times* (1888); *Les temps préhistoriques en Suède et dans les autres pays Scandinaves* (1895); *Kulturgeschichte Schwedens* (1906); and *La civilisation primitive en Italie depuis l'introduction des métaux*, 3 vol. (1895–1910). Montelius died in Stockholm Nov. 5 1921. See *Oscar Montelius in Memoriam* (Stockholm, 1922).

MONTENEGRO (*see* 18.766), a territory included in Yugoslavia, formerly an independent kingdom. The area of the district which corresponds to the old Kingdom is 3,733 sq. m. and the population (1921) 199,857.

Montenegro as a Kingdom 1910–8.—In 1910 Prince Nicholas took advantage of an apparent lull in the Balkan situation to proclaim himself King, a step welcomed in Vienna as a reversion to the old position of two competing Serb dynasties. But the unrest in Turkey soon forced Montenegro once more into close alliance with Serbia, and Nicholas, so far from resisting the current, was the first to embark on war in Oct. 1912. His lack of heavy guns and the imperfect discipline of his gallant troops compelled him to resort to Serbian military aid on a considerable scale before Scutari could be reduced in April 1913. Austria-Hungary insisted upon the surrender of Scutari to the new Albania, and threatened war. Nicholas only yielded to an international naval blockade of the Montenegrin coast, and Serbian troops were withdrawn from the Adriatic. The first Balkan war gave Montenegro and Serbia a joint frontier, the former Sanjak of Novi Pazar being partitioned between them; and Montenegrin troops joined Serbia against Bulgaria in the second Balkan war. Early in 1914 the Montenegrin statesman, Miušković, began serious discussions with Pašić for a financial and customs union between Serbia and Montenegro, a fusion of the two armies, a joint foreign policy and diplomatic representation, but retention of the two dynasties.

These negotiations became known to Vienna, who warned Petrograd that " Austria-Hungary would not remain a silent observer," and regarded union as a challenge to her Adriatic interests. On this, Sazonov advised Pašić to postpone the negotiations. But the movement for union was rapidly becoming irresistible when the World War broke out and the two States found themselves side by side in resistance to Austria-Hungary. Prince Nicholas and his sons were, however, jealous and reserved, blocking the action of the Serbian General Janković, who had been sent at Russia's instance to reorganise the Montenegrin Army. In May 1915 Prince Peter had a secret meeting in Dalmatia with the former Austro-Hungarian military attaché, Hubka, and in Nov., during the invasion of Serbia, Crown Prince Danilo, through his friend Baron de Kruyff in Sofia, made overtures to the Central Powers, offering to cut off the Serbian retreat to the coast in return for territorial concessions to Montenegro in western Serbia and northern Albania.[1]

During the retreat the attitude of the Montenegrin dynasty remained highly equivocal and the key position of Mount Lovćen was surrendered to the Austrians almost without a struggle. Parliament voted unanimously in favour of holding out to the end with Serbia, but the King negotiated on his own initiative without authorisation from his government, and on Jan. 1916 addressed a telegram of submission to Francis Joseph. Failing to obtain the terms which he had hoped, he and his family, with the Premier Miušković, fled to Italy. During the next two years his second son, Prince Mirko, intrigued in Vienna and was connected with various Austrophil projects for a vassal Yugoslav state under the Petrović dynasty; he died in 1918 in an Austrian sanatorium. Meanwhile, King Nicholas resided in France and tried to silence criticism from the Left by making Radović his Premier. But when the latter advocated the formal proclamation of union and a simultaneous abdication of Nicholas and Peter in favour of the Prince Regent Alexander, Nicholas threw himself definitely into the arms of the anti-unionists, and by the end of the War found his court reduced to a tiny clique of personal dependents and adventurers.

Union with Serbia.—When Austria-Hungary collapsed in Oct. 1918 and national councils were erected in all the Yugoslav provinces, the current in Montenegro set more strongly than ever in favour of union. A National Assembly was convoked on Nov. 12 at Podgorica and proclaimed the deposition of the Petrović dynasty and the union of Montenegro with Serbia. On the death of Nicholas the royal title fell into abeyance, as Crown Prince Danilo did not wish to assume it and his nephew Michael was a minor.

Even before the Balkan wars Montenegro was desperately poor, and in normal years had to import grain for its scanty population; only the dynasty had grown rich by its arbitrary methods. The long strain of war increased the misery tenfold, and acute discontent was aroused by the bad administration, favouritism and centralist tendencies of Belgrade. There were numerous cases of brigandage and party vengeance which were conveniently misrepresented abroad as a movement for independence. In 1924, however, a marked improvement began. In the summer of 1925 King Alexander paid his first official visit to Montenegro, and the remains of his great-great-grand-uncle the Vladika Peter (the greatest of Serbian poets) were transferred to a mausoleum built at the King's expense on the summit of Lovćen by the Dalmatian sculptor Meštrović. (*See* BALKAN WARS; SERBIA.) (R. W. S-W.)

MONTERO RIOS, EUGENIO (1832–1914), Spanish politician, was born at Santiago de Compostela, Corunna, Nov. 13 1832. He was originally intended for the priesthood, but became a barrister and a teacher of ecclesiastical history. In 1864 he was appointed professor of canon law at the University of Madrid, and in 1869 entered the Cortes. He followed Ruiz Zorilla and as Minister of Justice in General Prim's Cabinet he introduced a number of important judicial reforms and drew up the act of abdication of King Amadeo. In 1881 he helped to found the Radical party and became Minister of Justice in 1889. From 1894–5 he was president of the Senate. He was chief of the Spanish delegation which negotiated the Treaty of Paris with the United States at the close of the Spanish-American War of 1898. In 1899 he was again president of the Senate. In 1903 he was elected leader of the Liberal party and in 1905 became Pri
Minister. He resigned the leadership of the Liberal party
1906 and was president of the Senate for the third time fr
1909–14. He died at Madrid May 12 1914.

MONTESSORI, MARIA (1869–), Italian educationi
was born at Chiaravalle near Ancona. She studied at t
University of Rome and graduated in medicine in 1894, bei
the first woman in Italy to do so. She then took up the subj
of educating defective children. From the experience th
acquired, she came to the conclusion that similar metho
might be applied to normal children of a lower age, and af
a series of experiments on a small scale she extended them
a large number of children in certain private and public infa
schools in Rome. Dr. Montessori encountered a good deal
opposition from advocates of orthodox methods in educati
who regarded her system as destructive of discipline. At t
same time she was warmly supported by a certain number
enthusiastic reformers, experienced and otherwise. Her syste
was applied on a larger scale in countries where elementa
education was not under rigid state or municipal control a
not carried out according to fixed programmes. From 1900
1907 Dr. Montessori lectured on pedagogical anthropology
the University of Rome and in 1922 was appointed Governme
inspector of schools in Italy. Her ideas on education are s
forth in *The Montessori System* (1912), which has been tran
lated into English and other languages. (*See* EDUCATIO
MONTESSORI SYSTEM.)

MONTESSORI SYSTEM.—The Montessori system of educ
tion aims at self-education by the pupils themselves. The
are no time-tables, no set lessons, no classes. There are no
wards or punishments of the ordinary kind. The pleasure
succeeding and gettings things right is the only incenti
" Each child is doing what, for the time being, pleases him be

happens to take his fancy. Then and there his education begi
All kinds of interesting ' occupations ' are going on, and wherev
he goes he will get help and guidance from the teachers. If
gets tired of playing at this thing he goes off and plays at tha
But he is never idle, for whatever he does interests him." A
paratus, elaborately devised by Dr. Montessori, is provided f
the educational games by which the children acquire knowledg
and this " didactic material " constitutes a distinctive part
the originality of the system.

The first stage is to develop the senses of touch, sight a
hearing; both by games of various sorts and by guiding t
attention systematically to the association of things, names a
ideas. When a child washes his hands, for instance, he is giv
first cold and then hot water, and led to observe and unde
stand the difference; the distinction of rough and smooth
emphasised by the different cards for fingering and sorting. T
child to know the words, " hot," " cold," " rough," " smooth
and thus the knowledge of language is extended in all directio
(" high," " low," " thick," " thin," " round," " oval," etc.) b
fore any question of writing or reading arises. Ideas of form a
colour are given precision by games with blocks, cylinders, et
of varying sizes, to be fitted into frames, or with shades of si
to be arranged to match; touch is practised by playing t
games blindfold; hearing is developed by the " silence " lesso
and by the use of small cylindrical boxes containing stones, san
and different substances to be rattled by the children, wh
arrange them in order of intensity of sound and so forth. Sk
and neatness in the use of the fingers and movement of lim
are stimulated partly by the mobility of the light furnitur
which the children rearrange for their own comfort, and part
by games at tying and untying, hooks and eyes, dressing a
undressing, waiting on one another at table, washing up a
so on. Many of these occupations are preliminary to writing a
reading, and lead naturally up to both.

Writing comes essentially before reading, on the Montesso
system. Emery-paper letters gummed on cards are provide
with which the child is familiarised by games of hide and see

---

[1] Telegram of Tarnowski, to Burián, No. 1449, Nov. 11 1915, transmitting Danilo's wire to Kruyff.

tc., so that, without any active teaching of the alphabet, he nows them by sight, by name and by feeling. He learns how to nitate them, partly by a touch game of passing the fingers over ne paper letter, thus making the actual motion of writing, and artly by playing at pencilling and colouring with specially de-ised cards on which an outline is given. The child learns to rite before he knows that "writing" is what he is learning; the ounds and shapes of the letters being known it is a natural tran-tion to build up the letters and their sounds into words.

The next thing is for the child to "read"—not merely to e-translate into sound a word he has translated into symbol, hich goes with the acquisition of "writing," but to extract previously unknown idea from written or printed symbols of ne same sort not put together by himself. At any rate in so honetically spelt a language as Italian, this is very quickly earnt. Numbers of words, well known to the children, are written n cards, and various games are played in identifying them with neir objects; and from single words the children pass to phrases nd sentences, the teacher writing on the blackboard, for instance, uestions or orders which form part of a game. Arithmetic is ntroduced to the children's minds by the employment of count-ig games, in which an apparatus of striped poles, counters, etc., used. The whole curriculum is devised for the content and appy employment of the natural energies of the child, who is ft free to respond to his own impulses, under the influence of didactic material," rather than under the discipline of a teacher.

BIBLIOGRAPHY.—Report to English Board of Education, by .G. A. Holmes, *The Montessori System of Education* (Education amph., No. 24, 1912) contains a critical examination of the system. ee also M. Montessori, *The Didactic Material for the Education Children from 7 to 11 Years; The Advanced Montessori Method* 917–8); *The Montessori Method* (Eng. trans. by A. E. George, 919). (H. CH.)

MONTEVIDEO (*see* 18.778), the capital city of Uruguay, ad a population on Dec. 31 1923 of 407,249. The municipal evenues increased from $2,850,000 in 1916 to $4,590,000 in 1921, nd for 1924–5 were estimated at about $5,342,000. Extensive ort improvements by the Government deepened the entrance nd part of the harbour in order to admit the largest ocean-going essels, which formerly had been obliged to anchor outside. ocks, warehouses and loading equipment also were much improved. Three large meat packing plants (*frigoríficos*), two of hem American and one British, were added to the industrial tablishments of the city. Manufactures, though still relatively nimportant, included flour, paper, cigars and cigarettes, soap, ndles, shoes, textiles and knitted goods; there were also tan-eries, breweries and a sugar refinery. The general appearance the city was improved by new buildings and the extension of aving and lighting. The University of Montevideo had in 1922 4 teachers and an enrolment of 1,615 students.

MONTREAL, Canada (*see* 18.790), the commercial metropolis nd the largest city of the Dominion of Canada, had an area of bout 50 sq. m. and a population of 836,304 in 1924. The popu-tion at the Dominion census in 1921 was 607,063, and was more an half French and about three-quarters Roman Catholic; ws, who have increased largely in number in recent years, num-er about 6%.

The port is the second largest in America, with eight miles of eep water and wharfage with berths for a distance of 17 m.; 18 essels of 1,000 ft. in length can berth at the same time. A large heme of harbour improvements has been undertaken in recent ears, including the reclamation of 30 ac. of land for a new dry ock, the electrification of the water front, the building of a huge evator, wharves, warehouses, etc. The improvements to navi-tion in the gulf and river of St. Lawrence have resulted in a rge increase of tonnage; 1,194 ocean-going vessels of 3,932,637 ns passed through the harbour in 1922, as compared with 820 2,690,535 tons in 1913. Over a quarter of the total export trade Canada passes through Montreal, which is the greatest grain rt of the world. There were 2,820 factories in the city in 1924, cluding very large flour-mills. The form of municipal govern-ent underwent several alterations in the decade following 1911, nd eventually the control of municipal affairs was placed in the hands of an administrative commission of four, appointed by the provincial government.

The construction of a tunnel under Mt. Royal and the centre of the city by the Canadian Northern Railway Co., was an important engineering feat completed in 1918. The company (since merged in the Canadian National railway system) built an imposing new terminal station in the centre of the city at the tunnel head, supplanting its old Moreau street station. Electric trains running through the tunnel to the northwestern side of Mt. Royal caused the growth of a new suburb on that side of the mountain.

Education.—Important educational buildings erected since 1911 include the McGill Medical building, a magnificent structure that replaced the building destroyed by fire in 1907, the Macdonald Engineering building of McGill University; a large and finely equipped technical school in connection with Laval University; a new high school; a public library; an art gallery, and a fine pile of buildings to house Loyola College, a Jesuit school of high standing.

McGill University, benefiting by gifts from Sir William Macdonald, was able to develop further its faculty of music, to establish new degrees in law, commerce and household science, and to extend some of its departments. A school of physical training was opened in connection with the university, and a department of social service was inaugurated. The McGill stadium, one of the finest athletic amphithéatres in North America, was opened in 1918. After the death of Sir William Macdonald in 1919, provision was made for the further endowment of Macdonald College at Ste. Anne de Bellevue, the university's agricultural centre, and in 1924 Lady Strathcona gave £24,000 for a zoological department. The administrative buildings of the Montreal branch of Laval University were destroyed by fire in the autumn of 1919. A movement, that had been gaining strength for some years, to separate the Montreal branch from Laval University at Quebec, culminated in the foundation of the University of Montreal, the buildings of the old branch of Laval being taken over by the new institution. A number of new courses were added, including social and political science, and the faculty of applied science was further developed. Considerably over $3,000,000 was raised by public subscription as a building fund.

MONYPENNY, WILLIAM FLAVELLE (1866–1912), British journalist, was born in Ulster Aug. 7 1866. Educated at Trinity College, Dublin and Balliol College, Oxford, in 1893 he joined the editorial staff of *The Times* (London), and early in 1899 became editor of the Johannesburg *Star* in the Transvaal. He played a useful part, as a publicist, on the side of the Reform party there, and when war came he joined the Imperial Light Horse and was one of the defenders of Ladysmith. Returning afterwards to his position on the *Star*, he did much to promote Lord Milner's work of reconstruction, but resigned in 1903 owing to his hostility to the introduction of Chinese labour into the mines. He was then entrusted by *The Times* with the task of writing the official biography of Disraeli, and also did other work for that paper, becoming in 1908 a director of the company. Owing to ill health the first volume of the *Life of Benjamin Disraeli, Earl of Beaconsfield* (ultimately extending to six volumes) did not appear until 1910, and the second shortly before his death. It was completed in 1920 by Mr. G. E. Buckle, formerly editor of *The Times*. Monypenny died in the New Forest, Hampshire, Nov. 23 1912.

MOODY, WILLIAM VAUGHN (1869–1910), American poet and playwright, was born at Spencer, Ind., July 8 1869. He was educated at Harvard University and was assistant in English there 1894–5. From 1895 to 1907 he was at the University of Chicago as instructor and, after 1901, as assistant professor. He died at Colorado Springs Oct. 17 1910. Moody was the author of the *Masque of Judgment* (1900); *Poems* (1901); *The Fire-Bringer* (1904); *The Great Divide* (1907) and *The Faith Healer* (1909). He compiled (with Robert M. Lovett) *A First View of English and American Literature* (1902), and edited *The Complete Poetical Works of John Milton* (1899, Cambridge ed.) and (with George Cabot Lodge and John Ellerton Lodge) *The Poems* *of Trumbull Stickney* (1905). His complete works were edited with an admirable introduction by Prof. John M. Manly (1912).

MOOKERJEE, SIR ASUTOSH (1864–1924), Indian jurist and educationist, son of a medical practitioner, was born at Bhawanipur, Calcutta, on June 29 1864. Graduating at the Presidency College, Calcutta, in 1885, he gained the doctorate in laws in 1894. He wrote much for learned societies on mathematical subjects, and his "Geometry of Conics" (1892) and other papers were incorporated in text-books for Cambridge University. He became a fellow and syndic of Calcutta University in 1889, and was appointed to the Tagore law professorship in 1898. From 1904 until his resignation in 1923 he was a judge of the Bengal high court, and won a great reputation as a jurist. He was knighted in 1911. His spare time from the Bench was devoted with unflagging zeal to the affairs of Calcutta University. He was a member of the Calcutta University Commission 1917–9, and signed the report without dissent, but afterwards offered strong opposition to the projected legislation. Though advanced in some matters of social reform, he lived very simply as an orthodox Brahman. He died at Patna on May 25 1924. His *Addresses, Academic and Literary*, were published in 1915.

MOORE, GEORGE (1852–), Irish writer (*see* 18.808), broke fresh ground in 1916 with *The Brook Kerith*, a work of fiction based on the Gospel story. He had professedly taken leave of literature in three remarkable volumes of quasi-reminiscences, entitled *Ave* (1911), *Salve* (1912) and *Vale* (1914). Later he produced two privately printed volumes de luxe, *Avowals* (1918) and *A Story Teller's Holiday* (1920), and retold the story of *Abélard and Héloïse* (1921). In 1922 he published *In Single Strictness* and 1926 *Ulick and Lorachal*.

MOORE, JOHN BASSETT (1860–), American jurist, was born at Smyrna, Del., Dec. 3 1860. He graduated at the University of Virginia in 1880, studied law in an office in Wilmington, Del., and was admitted to the Delaware bar in 1883. Two years later he entered the Dept. of State as a law clerk, and in 1887 was appointed third assistant secretary of state. He was secretary to the conference on Samoan affairs in that year and U.S. secretary at the conference on the North Atlantic fisheries, 1887–8. He was appointed professor of international law and diplomacy at Columbia University, 1891, frequently being granted leave of absence to accept appointments in the national interest. On the outbreak of the war with Spain in 1898 he was appointed Assistant Secretary of State, and he acted as secretary and counsel to the U.S. Peace Commissioners at Paris at the close of the War. Among the later official positions which he filled were those of U.S. agent before the United States and Dominican Arbitration Tribunal, 1904; U.S. delegate to the Fourth International American Conference at Buenos Aires, 1910; special U.S. plenipotentiary to the Chilean Centenary, 1910; U.S. delegate to the International Commission of Jurists, Rio de Janeiro, 1912; counsellor to the Dept. of State, 1913; a member of the Permanent Court of Arbitration at The Hague, 1913; U.S. delegate to the Pan-American Financial Congress, 1915. He was appointed in 1921 a judge of the Permanent Court of International Justice. He was also the U.S. delegate and chairman of the International Conference on rules for aircraft and radio in time of war held at The Hague 1922–3.

Moore's publications include *Extradition and Interstate Rendition* (1891); *History and Digest of International Arbitrations*, 6 vol. (1898); *American Diplomacy: Its Spirit and Achievements* (1905); *Digest of International Law*, 8 vol. (1906); *Four Phases of American Development* (1912); *Principles of American Diplomacy* (1918); *International Law and Some Current Illusions* (1924); and *The Permanent Court of International Justice*, a pamphlet (1924).

MORALE: IN WAR.—Modern conditions of war are gradually extending the domain of *morale* and increasing its influence. For, among belligerent nations, war affects a greater number of people and does so with methods of increasing violence.

I. THE SOLDIER IN THE RANKS

In battle, an enemy's long-range guns make their effects felt as far back as 5, 10 or 15 m., and, as they are capable of rapid firing, their effects become formidable to troops even at those dis-
tances. Difficulty in seeing their objective does not limit th
powers, for they are aided by aeroplanes which inform them co
cerning the situation of their objective and the results of th
fire. At lesser distances they are supported by light artillery
large numbers, mobile, and capable of making the most a
vantageous use of chance features of the ground over the who
of the area at their command; and further support comes fro
machine-guns, which, of light weight and slender dimensio
can penetrate everywhere to equip in a short time the whole
the terrain.

Range of Fire.—It follows, then, that the soldier who a
proaches the battlefield and advances to carry the enemy po
tion, finds that, at great range and over an extremely wi
extent, that is to say during a long space of time, he is expos
to a heavy fire, the effects of which are multiplied in severity t
further he advances to the position. Frequently, before bei
able to advance, he is forced to wait until, thanks to supplies
material, cannon, trench mortars and machine-guns, his arn
has gained a mastery of the fire, and the destructive capaci
of the adversary has been thus reduced.

In this time of waiting hours succeed hours, nights follo
days and weeks go by, always under the rain of steel from t
enemy. It is under incessant bombardment that the march
victory has to be resumed and continued. Rarely is the batt
decided in one day. And the nervous tension, the crisis impos
on the combatant, lasts the same time. During all this weari
period he must fulfil, automatically and often left to his ow
resources, his function as soldier, marksman, machine-gunne
pioneer, link in the chain of intelligence, carrier of supplies a
so on. That is to say this function must be part of his own n
ture, and to fulfil it he must have received a serious training.

Interception of Supplies.—Furthermore, bombardment sprea
its havoc no less widely on the rear of the battle-front, cu
communications, prevents the arrival of supplies. Not only h
the combatant to show a bold face to the danger which threate
him, but he often finds himself reduced to a most precario
existence; along with the rigours of nights in the open, he has
put up with shortage of supplies. And thus physical exhausti
comes to be added to nervous shock, and the severity of th
ordeal is heightened.

Tenacity and Endurance.—In the wars of the past, moveme
and enthusiasm, the qualities of dash and courage and person
pride, could suffice the soldier in a moment of intoxication
meet, with brilliance, the crisis of collision with the enem
But to-day, if he is to traverse the long road of the hell which
the modern battle and reach a decision, he must possess an u
breakable tenacity and an energy ready for any sacrifice, an
both must be unwavering for long days on end. To what grea
ness of soul must we not appeal, then, to see the emergence
virtues so solid, so tenacious, so generous? We must leave th
answer to the soldiers of the Marne and Yser, Ypres and Verdu

Further, who can forget the moving spectacle of the Britis
leave-trains returning to the front during the War? The me
were accompanied to the station by a silent throng composed f
the most part of women and children. A few handkerchie
furtively sought the eyes of those who were left behind, especiall
when the train began to move off. On board the vessel at Dove
the returning men donned their life-saving waistcoats, and stoo
closely crowded together on deck, imprisoned in their ow
thoughts. If, from a group here and there, came a song or
noisy demonstration, it was from young soldiers going out to th
front for the first time. The others remained impassive, silent
gloomy, and their eyes gave token of the cold energy and th
spirit of savage resolve on which they had fallen back. It was t
the cry of "*Lusitania!*" that they would soon be marching t
attack. Experience had taught them that mere knowledge o
their duties and a fine, fleeting ardour would not suffice to bea
the long and bitter ordeal of the modern battle. They require
a spirit which must be imbued with the highest feelings, and
quickened with them, a spirit proved in the crucible of disciplin

The soldier of our national armies has drawn the spirit o
sacrifice, the sentiment of discipline and duty, from love of hi

ountry, from attachment to the family as to the race, and from ie indispensable military training, which left its strongest impres- on. Of this he gives proof in action by strict obedience to orders. ut let there be no mistake; he conserves and maintains these rtues in lasting fashion only in proportion as the commanders ave won his confidence by the care with which they surround s daily life; only in proportion as they know how to conserve at life by their vigilant economy of his blood.

As a whole, the war of the present day demands of the soldier moral greatness, and a professional training, both developed very high degree. The conservation of those forces, a conserva- on which alone can assure victory, is incumbent on the com- anding officers. And in this way the rôle and responsibility of e officer expand in an exceptional degree, and grow sharply efined, especially in battle.

II. THE OFFICER

In the course of any action of necessarily long duration, the ficer can conserve the value of his unit, section, company or ttalion, only by protecting it from the disasters which are ntinually menacing it, and by leading it step by step to the al, to the final objective which has been assigned to it by the gher command, and the gaining of which constitutes for it e victory. He cannot confine himself to being a daring soldier, perior to his subordinates by his courage and personal example. e must show himself to be constantly dominated and impelled ' a double preoccupation: to avoid the destruction of his unit d to bring it nearer its objective.

Avoidance of Loss.—To avoid its destruction, because he is in e presence of an armament capable, by suddenly inflicted sses, of destroying the unit, or at least of shattering its *morale* r a long time, if adequate precautions have not been taken in me. Hence springs the necessity that he should be familiar th the dispositions appropriate to this continual menace, and at he should be able to order and put readily into practice ese dispositions, which by his selection of rendezvous, his ctical formations, by hastily constructed earthworks or by any her procedure, keep the troops halted under cover from the servation, projectiles or poison-gas of the enemy.

How many long hours will not troops have to pass in waiting, preparation, before seeing the moment for action arrive? ow often has not the officer to provide for these secure dis- sitions? Yet in this situation the slightest negligence is un- rdonable. At that moment will appear all the vigilance and the power of decision which the officer must bring to the field action, in addition to the acquired knowledge and the experi- ce, necessarily incomplete though this be, of manoeuvres. hat is required of him, even at these moments, is the all-embrac- g eye, the sense of fitting opportunity and the gift of decision.

Precision in Attack.—Then, the moment of action having rived, the operations of the unit must be carried out without sitation or disturbance, in the presence of an adversary who, nging all his resources again into action, may be able to regain me of his preponderance, to restore to his armament its rmidable strength. That is to say, the operations must have en directed in all their details by a commanding officer who has eviously assured himself of the participation of neighbouring oops, and has gauged as exactly as possible the position of the emy which he is approaching.

To sum up, together with the feeling of readiness for action lled up by the receipt of orders, but before the moment for tion has come, it is by foresight and precision that an officer ould be inspired and guided in his procedure. Without these steps into imprudence, and he draws his troops along with him. hey run the risk of not returning. He, and he alone, is to blame.

Value of Experience.—Without going into the increased need r technical knowledge resulting from the employment of ma- rial, at once more various and more potent and also more deli- te, the art of bringing troops on to the battlefield has assumed our day a capital importance. Every officer ought to concern mself with this, and shape himself for it in time of peace as lly as he devotes himself to the instruction of his men, so that he may be able, when the great day comes, to present himself armed with a certain peace-time experience, and armed above all with faculties well maintained, developed, and turned ever on the alert in the direction of the march toward the objective. He must be ready on that day to resolve the difficulties of this march, difficulties which only the actual conditions will reveal to him, for peace gives no complete idea of the effects of modern weapons on a body of troops. War will bring him face to face with new problems, and will demand that he possess, over and above his professional knowledge, the habit of reflection and prompt decision on fresh circumstances. It is a habit which he will need to have acquired during peace-time.

It is needless to remark that these faculties of foresight, of adaptation to new problems, ought to be developed the more fully in an officer the higher his rank and the greater the instruments of control which are in his hands. For in this case his orders cover vast spaces, are laden with more far-reaching consequences, and are more difficult to modify in their execution. The moral forces and the capacities which the commander must bring to war, if he is to act in such a way that negligence or imprudence, both always disastrous, may be avoided, have increased in notable proportions, even for the lower ranks.

III. THE NATION

But war, to pursue the theme further, does not confine its material and moral effects to the battlefields and the invaded regions. It extends them toward the rear, to populations which were formerly kept aloof from it by the barrier of distance. It spreads them overseas in every direction, even to non-belligerents, and produces the most complete upheaval.

The Non-Combatants.—In the rear, not to speak of refugee populations fleeing before the ravages of invasion, and terror systematically loosed in defiance of the laws of humanity, it is the women, the children and the aged who live in the emotions of the struggle, as a result of the facility and speed of communications; who undergo on occasion the stress of hostile bombardment from the air; who in any case suffer privations of every kind. This means that the field is open, in the heart of the country itself, to the most opposed sentiments and passions, as also to nervous shock and physical exhaustion. But, despite these difficulties, the interior of the country must hold firm to the end, and, what is more, must maintain in foodstuffs, arms, and munitions and support in energy of spirit, those who fight at the front. In its united aspects, the country becomes and must remain by its sentiments and its productive activity the source of the warring capacity of the armies.

Thus, in the old Europe, each country is perforce the near neighbour of powerful states, sees its warlike resistance measured by the degree of union between the interests and sentiments which it comprises, by its jealous watch over its independence, by its progress toward that moral unity which is the essence of a nation, and consequently by the depth of its national sentiment. Only in these moral factors is to be found the energy which will resist concussions of every kind, and will pursue, through ever-increasing sacrifices and through all the vicissitudes of the struggle, the success of the enterprise which will liberate it, once and for all, from all its anguish.

And if, among the states of the New World, where menace is less direct, the immediate danger does not demand the organisation of territorial defence, a blow struck against the principles whereby they live will awaken the apprehensions of the peoples and, in community of sentiments, will arm them for the safeguarding of their free civilisation. In short, a sturdy sentiment which binds the entire people as one, imposing itself upon them by the justice of their cause and the necessity for defending it, is indispensable to the success of a modern war, for that alone is capable of obliging them to the privations and sacrifices which war entails.

IV. THE GOVERNMENT

To maintain and guide this sentiment during the days of the struggle, to exploit it and to extract victory from out of it—

such is the task of the Government. In these days the Govt. must not be simply the representative of the interests of the country, but rather the expression of the passions which are animating it, and to that end, the organiser of defence, the creator of the material resources, the arms, munitions, foodstuffs essential to the struggle, and the motive and inspiring power and of the forces assembled on the field of operations. It must show itself a "war government," with an active and effective policy, taking a wide view of the ends which it is possible to attain, bearing in mind the means at its disposal. And it must be animated by the will always to augment those means to hasten those ends, while still maintaining, in the interior of the country, the spirit which does not disarm.

It is obvious, then, that war calls for peculiar qualities in the statesmen who preside over it. Without these, it must inevitably end in impotence, or even defeat.

V. CONCLUSION

To sum up, whether we are dealing with the soldier, the high command, the nation or the Govt., in each of these divisions war demands an ever-increasing share of the moral forces whose close union and wise combination are alone capable of producing victory. It is to the insufficiency of certain of these forces, or to the lack of cohesion between them, that we must look to grasp and explain the collapse, in the course of the last war, of certain Great Powers, and likewise of armies of formidable repute, which in themselves certainly did not fall short of that repute.

Bibliography.—The most important works to be consulted are those of Marshal Foch himself: *Des Principes de la guerre* (1903) with English translation by Hilaire Belloc (1918); *De la conduite de la guerre*, 3rd ed. (1915); *Préceptes et Jugements du Maréchal Foch; extraits de ses oeuvres, précédés d'une étude sur la vie militaire du maréchal par A. Gasset* (Nancy, 1919), with English translation by Hilaire Belloc (1919). See also J. R. (ancien élève de l'école supérieure de guerre), *Foch. Essai de psychologie militaire* (1921), and Émile Mayer, *La psychologie du commandement: Avec plusieurs lettres inédites du Maréchal Foch* (1924). (F. Fo.)

MORANT, SIR ROBERT LAURIE (1863–1920), British civil servant, was born at Hampstead April 7 1863. He was educated at Winchester and New College, Oxford, and on leaving the university was for a few years a schoolmaster. Later he went to Siam as educational adviser, and was entrusted by King Chulalongkorn with preparing a scheme of education for the whole country. In a few years he returned to England, and after some experience of social work in the East End of London, was appointed in 1895 to assist in the direction of the office of special inquiries and reports in the Board of Education. He became private secretary to successive ministers, and on him devolved a great deal of the preparation of Mr. Balfour's Education Act of 1902. In 1903 he was appointed permanent secretary of the Board of Education. In this capacity he proved himself a most efficient administrator, and in 1907 he was created K.C.B. In 1912, on the introduction of the National Insurance bill, Morant was appointed chairman of the Insurance Commission, a position which led naturally to his appointment as secretary to the Ministry of Health on its formation in 1919. He died in London, after a few days' illness, March 13 1920.

MORE, PAUL ELMER (1864–), American author, was born at St. Louis, Mo., Dec. 12 1864. He was educated at Washington University and Harvard, and he was assistant in Sanskrit at Harvard, 1894–5, and associate lecturer in Sanskrit and classical literature in Bryn Mawr College 1895–7. He was literary editor of *The Independent* 1901–3, and of the New York *Evening Post* 1903–9, and editor of *The Nation* 1909–14. In 1915 he was elected to the American Academy of Arts and Letters.

He is the author of *Shelburne Essays* (11 vol., 1904–); *Life of Benjamin Franklin* (1900); *Platonism* (1917); *The Religion of Plato* (1921); *Hellenistic Philosophies* (1923); and *The Christ of the New Testament* (1924), in addition to a number of translations from the Greek.

MORESNET: *see* Eupen and Malmédy.

MORET Y PRENDERGAST, SEGISMUNDO (1838–1913), Spanish politician, was born at Cadiz June 2 1838. He was educated at the Central University, Madrid, and became pr fessor of political economy there. In 1863 he entered the Cort as a Liberal, took part in the revolution of 1868 and in the co stituent assembly of 1869. Colonial Secretary in 1870 und General Prim, and later finance minister, he was for a few mont in 1872 Spanish ambassador to Great Britain, and after resigni this post accepted the directorship of a large London bank. year later he returned to Spain. He re-entered Parliament 1879, and helped to found the Democratic dynastic party. was Minister for Foreign Affairs under Sagasta in 1885 and aga in 1893–4, Minister of the Interior 1885–8, and Minister Colonies 1897. In this capacity he advocated the grant of auton my to Cuba and Porto Rico, and was opposed to the war wi America of 1898. He was Prime Minister in 1905–6 and aga in 1909, and at the time of his death in Madrid on Jan. 28 191 was president of the Chamber. He had a cultivated mind ar a noble spirit but was not sufficiently resolute for the difficu political times in which he lived.

MORGAN, ARTHUR ERNEST (1878–), American eng neer and college president, was born at Cincinnati, O., June 1878. He received his early education in the high schools St. Cloud, Minn., and then spent three years in Colorado various occupations, including a short term at the Universit of Colorado. Returning to Minnesota, he worked for his fathe a land surveyor, and studied engineering at night. In 1902 commenced practice for himself at St. Cloud, making a speci study of floods and flood control. In 1907 he became supervisin engineer of U.S. Govt. drainage investigations, but in 190 founded the Morgan Engineering Co., of which he became pres dent. His firm undertook many reclamation projects in th southern states. In 1913, after the Dayton flood, he was co sulted on behalf of the sufferers with a view to prevent a recu rence of the disaster, the result being the formation, unde special statutory powers, of the Miami Conservancy Distric consisting of all cities, towns and land within the flood area, an the necessary work was done under his supervision as chief engi neer. In 1921 he acted as chief engineer to the Pueblo Conserv ancy District, formed to protect Pueblo, Colo., from floods. H planned and superintended a large number of projects for wate control, and drafted or assisted to draft drainage codes for number of states. In 1921 he was appointed president of Anti och College, Yellow Springs, O., which was reorganised, unde his inspiration, in order to carry out a comprehensive experi ment in the correlation of cultural and industrial education (*se* Antioch College).

He was the author, among other works, of *The Drainage of th St. Francis Valley in Arkansas* (U.S. Govt. 1911); and *The Miam Valley and the 1913 Flood* (1917).

MORGAN, JOHN PIERPONT (1837–1913), American financie and banker (*see* 18.834), died in Rome March 31 1913. I Jan. 1913 he sailed from New York for Egypt, where he becam seriously ill. He was carried to Italy but never recovered. Hi will provided that after the distribution of enumerated bequest amounting to about $17,000,000, chiefly to his family, th residue of his estate should pass to his son, John Pierpon Morgan. In 1916 the estate was finally appraised at $69,499,73 He left only some $700,000 to charities; but while living h had been a generous giver, and in his will suggested that hi son continue certain accustomed annual contributions. Hi works of art and books were left to his son without restrictions although in his will he said: "It has been my desire and inten tion to make some suitable disposition of them or of such portio of them as I might determine, which would render them per manently available for the instruction and pleasure of th American people." In the summer of 1913 most of the ar collection was placed as a loan exhibit in the Metropolita Museum of Art, New York City. Later, some items, mostl replaceable, were sold. The remainder, consisting of over 3,00 pieces, was presented to the museum by the son in Dec. 1917 and a new wing was added to the building to house the permanently. This was opened in June 1918. This collection covered all periods and included matchless bronzes, enamels, orcelains and tapestries. The library (dedicated by the son y public charter in 1923 as an institution of research for cholars and provided with liberal endowment, in memory of is father) was appraised at $7,500,000, and consisted of about ,000 volumes of illuminated manuscripts, early printed books, xamples from famous presses and association copies.

MORGAN, JOHN PIERPONT, JR. (1867–), son of John Pier- ont Morgan (1837–1913), succeeded his father and continued as ctive head of J. P. Morgan and Co., and of its associated anking houses in Philadelphia, London and Paris. He was orn at Irvington, N.Y., Sept. 7 1867, prepared for college at t. Paul's School, and graduated from Harvard in 1889. He eceived the honorary degree of LL.D. from Cambridge Uni- ersity in 1910 and from Harvard in 1923. In 1891 he became member of the firm of which his father was the head, and ter spent 12 years with the London house of J. S. Morgan and o., now Morgan, Grenfell & Co. Within 16 months after Mr. lorgan succeeded his father in 1913, as head of the house, the 'orld War began. Almost immediately the finance department the City of New York became confronted with a grave tuation. Owing to the dislocation of the foreign exchanges, e City of New York found itself unable to meet its obligations aturing in London and Paris, aggregating upwards of $80,000,- o. Thereupon Mr. Morgan undertook the organisation of a ccessful bankers' syndicate for $100,000,000 gold, through the eration of which the city's credit was maintained intact.

Within a year the British Govt., followed by the French ovt., enlisted the services of Mr. Morgan and his partners undertake the vast work of co-ordinating and finally pur- asing in the United States their all-important supplies of odstuffs and munitions. The purchases which the firm made r the British and French governments aggregated several lion dollars, and the work which the Morgan firm accom- shed in organising sources of industrial supply in America oved of great service to the United States Govt. when, o years later, in 1917, it undertook to secure its supplies on a huge scale for the prosecution of its part in the War. fore America's entry into the War, Mr. Morgan under k the work of financing a great part of the Allies' require- nts for credits in the United States of America, and prior to ril 1917 had arranged total loan issues to the British and ench governments of $1,550 million. During the period of rld reconstruction following the War, Mr. Morgan continued ive; the publicly issued loans which his firm arranged to eat Britain, France, Belgium, Italy, Austria, Germany, itzerland, Japan, Argentina, Australia, Cuba and Canada gregating between April 1917 and April 1926 approximately 700 million. During America's participation in the War, Mr. rgan served as a member of the Liberty Loan and other ortant committees. For five years he was a member of the visory council of the Federal Reserve Board. In 1922, at request of the reparations committee, he served at Paris n a committee of bankers whose report, laying down the entials of the German reparations problem, was an important liminary to the work of the Dawes committee two years r.

n 1920 Mr. Morgan presented his residence at Prince's te, in London, to the U.S. Govt. for an embassy. In 3, by public charter, he dedicated his father's library (to ch he had made important additions) as an institution research for scholars, at the same time providing liberal owment for it. Under the terms of the gift it will be pre- ved intact as a complete unit for the period of 100 years n March 31 1913, the date of his father's death.

ORLEY OF BLACKBURN, JOHN MORLEY, VISCOUNT (1838– 3). British statesman and author (*see* 18.840), continued to the seals of the India Office till Nov. 1910. One of his last ial acts had been to resist the appointment of Lord Kitchener he vice-royalty, pressed strongly upon ministers by King ard just before his death. Lord Morley remained in the inet in the less onerous position of Lord President of the ncil, and was one of the four counsellors of state to administer the kingdom during King George's visit to India for the Delhi Durbar in the winter of 1911–2.

In the critical period of domestic politics which began with the budget of 1909 he played a somewhat prominent part. He defended that budget in the great debate of Nov. 1909 and, while admitting that the Lords had the legal right of rejection, said that to assert it was a "gambler's throw." Owing to the temporary failure of Lord Crewe's health, Lord Morley led the House of Lords during most of the session in which the Parliament bill, which he warmly supported, was passed; and it was he who read out to the House on the last night of debate that definite assurance from King George of his assent to a creation of peers which finally secured the exiguous but adequate majority of 17. He not only took charge of the India Office during Lord Crewe's illness, and of the Foreign Office in Sir Edward Grey's short holidays, but he was an outstanding figure in the Home Rule debates of 1913 and 1914.

The entrance of Great Britain into the World War brought Lord Morley's official career to an abrupt termination. He felt that his pacifist outlook was sufficiently well-known to make it unnecessary for him to give reasons for resigning; and he withdrew to the retirement of his Wimbledon villa, where he occupied himself with writing two most interesting volumes of *Recollections*, which were warmly welcomed on their publication in 1917. In 1921 his publishers brought out a complete edition of his works in a handsome *format;* and he was generally regarded, during his last years, as sharing with Mr. Hardy the position of *doyen* of English men of letters. He died at Wimbledon, London, after a somewhat long period of ill health, on Sept. 23 1923. See Viscount Morley, *Recollections*, 2 vol. (London, 1917).

MOROCCO (*see* 18.850), a state of Northern Africa. The district of Tangier (*q.v.*) is internationalised; the northern zone is a Spanish protectorate; the remainder a French protectorate. The approximate area is 231,500 sq. m. (Spanish zone, 18,360 sq. m.; Tangier, 200 sq. m.). The estimated population (1925) is: French zone, 4,410,000; Spanish zone, 500,000; Tangier, 70,000. The reigning Sultan in 1925 was Mulai Yusef.

I. POLITICAL HISTORY

In Oct. 1910 there was a general rising of the tribes round Fez against Mulai Hafid, who had become unpopular owing to his dependence on the French and the exactions of his grand vizier. Fez was besieged in March 1911. In April and May French troops were sent to occupy Fez and pacify the district. This action, although its necessity had been notified to the Powers, was resented by Spain and Germany. In June Spain occupied El Qsar and Larache (El 'Araish). On July 1 the German Govt. suddenly dispatched the gunboat "Panther" to Agadir, nominally to protect the interests of German subjects (*see* EUROPE). The situation was so critical that war seemed imminent; but Great Britain declared her intention of standing by the entente, and her formal objection to Germany's obtaining territorial influence in Morocco. France and Germany signed a treaty on Nov. 4 1911; in return for territorial cessions in the Congo, Germany recognised France's political protectorate (the word was used in the letters accompanying the treaty, although not in the treaty itself) over Morocco, economic equality between the two countries being reaffirmed.

The Franco-Spanish Treaty.—On Nov. 27 a Franco-Spanish treaty was concluded. This arranged such debated points as customs, the management of the projected Tangier-Fez railway and the appointment of the Sultan's *khalifa* (deputy) at Tetuan. It slightly revised the Franco-Spanish boundaries determined by the convention of Oct. 3 1904. The boundary of the northern Spanish zone follows the Muluya from its mouth to near Meshra 'Klila; thence, turning west, it runs immediately north of the Wad Wergha R. to Jebel Mulai bu Shota; thence it strikes northwest to the Wad de Kkus, follows its course, and, afterwards, Lat. 35° N., to the Atlantic coast. Both banks of the Lekkus and El Qsar and Larache fall within the Spanish zone. The treaty also recognised the rights of Spain in the south over the enclave of Ifni, bounded to north by the Wad bu Sedra, to south by the Wad Nun, to east by a line about 15 m. from the coast. The negotiations of 1911–2 between the Powers resulted in the internationalisation of the Tangier zone, consisting of Tangier, its environs and the territory of the El Fahs tribe to south and west of it—about 100 sq. m. in all. By this understanding Tangier was "to be given a special régime to be agreed upon later."

In 1913 a commission sat to determine the nature of this régime; but its findings were not accepted by Spain, and the outbreak of the World War shelved the question. A convention determining the new régime was drawn up on Dec. 18 1923 (*see* TANGIER). On March 30 1912 Mulai Hafid signed a treaty with France accepting the protectorate, which was subsequently recognised by the Powers, who withdrew their diplomatic representatives. General Lyautey was appointed resident-general.

On Aug. 12 1912 the Sultan Mulai Hafid abdicated, appointing as his successor his brother, Mulai Yusef. (E. G. S.)

II. ADMINISTRATIVE HISTORY

General Lyautey's Administration.—The history of French Tangier from 1911 to 1925 was largely military (*see* MOROCCO, CAMPAIGNS IN). France was fortunate in possessing a remarkable administrator in the resident-general, General Lyautey, who was assisted by remarkable subordinates: Generals Poeymiran, Henrys, de Sumothe, Colonel Huot, etc. Instead of evacuating the interior of Morocco during the War, Lyautey was able to extend his control in it, and even to continue public works and hold fairs and exhibitions to maintain confidence. By the end of the War he was well on the way to becoming master of "le Maroc utile," that is, such parts of the country as possessed a real military, political or economic interest. The pacification was complete in 1923; but in April 1925 the Riff outbreak in the Spanish zone extended to the French zone. Lyautey resigned on Sept. 29 1925. Regret was unanimous, and was freely expressed by Sultan Mulai Yusef and the natives, who remembered the "generosity and broadmindedness" which had been the ideal and practice of his policy. Few, if any, Christians had enjoyed such a privilege as he: all Morocco prayed for him in the mosques during his illness in 1923. His successor, M. Theodore Steey, who had successfully filled the post of Governor-General of Algeria, was appointed on Oct. 3 1925.

The Sultan's Govt.—In his difficult task Lyautey enjoyed the loyal co-operation and help of the Sultan, who generally resided at Rabat, the seat of government. Close attention was paid to the maintenance of the Sultan's prestige, and his authority and initiative were carefully respected in internal affairs, the measures decided by him being, however, always taken in accord with the French authorities,[1] by application of the treaty of Fez (March 30 1912). Mulai Yusef, on succeeding to his brothers Abdel Aziz and Hafid, immediately continued and completed the reforms, already begun, of the *Maghzen* (Central Govt.), especially in the matter of native justice and religious land property (habus). He worked regularly with his viziers (the Grand Vizier and the ministers of Justice, Domains, Habus, Public Instruction, and the presidents of the High Sherifian Tribunal and the Tribunal of Appeal of the Chraa (Mussulman law), seven in all, taking a special interest in educational matters. The competency of the local judge, the Kadi—*i.e.*, in reality, a religious magistrate, civil matters relating to marriage, the family and inheritance, etc., being regulated by the Koran—has been maintained towards Europeans in the matter of the acquisition[2] of land property (Articles 11 of the Madrid Convention, July 3 1880) and 60 of the Algeciras Act (April 7 1906). Hence the importance of the Ministry of Justice and of the tribunals.

The Sultan remains the head and tutor of all the members of the Sherifian house. He appoints a special Sherif (the "mezuar" or "naquib") in all the principal towns, who settles disputes between the Shorfa Alauites (*i.e.*, the above members) and watches over their
conduct. He has four "Khalifas" in Fez, Marrakesh, Tiznit ar
the Spanish zone, whose rôle is of a representative character. Tl
civil list amounts to 5,250,000 fr., *plus* 2,200,000 fr. for the Sultar
special negro bodyguard.

Pashas in the towns and Kaids among the tribesmen in the cou
try represent the temporal authority of the Sultan, as opposed
the Kadis (*see* above), and are in charge of criminal justice and jud
also in cases where movables and commercial matters are concerne
In the principal towns they are controlled by the French officials
the Protectorate acting as commissaries of the Government. Ca
has been taken to preserve as far as possible among the Berb
tribes the customs (izref) to which they are deeply attached. The
Kaids are judges in penal and commercial matters; disputes as
personal status, property, etc., being settled by the djemaas (popul
assemblies) according to custom and not by the Kadis.

Native Representation.—Arrangements were made for taking t
advice of the natives on certain questions. The programme of tl
monthly meeting of the Council of Government is communicate
not only to the Maghzan but, through the French "contrôleurs,"
week beforehand, to the native sections (created by a *dahir* of Ja
20 1919) of the chambers of commerce and agriculture, who, as occ
sion offers, deliberate either separately or concurrently with t
French sections. They are also represented in the municipal counc
presided over by the pashas in the principal towns. In both cas
they are appointed by the Government.

French Administration.—The administration is under the autho
ity of the "Commissaire" Resident-General (decree of June
1912), assisted by a delegate and a secretary general of the Prote
torate. The central government comprises the secretariat gener
to which are attached the following services: civil control, personn
legislative studies, general security, general administration, per
justice and the special direction of native affairs and the intelligen
service. The other central services are divided up between the f
lowing Directions générales: 1. Finances and public domair
2. Public works (with the mines, ports, mercantile marine and t
post, telegraph and telephone office; 3. Agriculture, commer
(and industry) and colonisation (with the forests and the la
registrations and survey); 4. Public instruction, fine arts a
antiquities; 5. Public health. The "exterior services" are class
by regions, Shawiya, Rabat, Gharb, Ujda, etc.), and distribute
between 22 controls (and their annexes) or municipalities in the ci
territory; and eight regional bureaux, with their 14 circles, in t
military zone. The French judicial organisation, which comes in
play whenever Frenchmen or Europeans are concerned, compris
12 civil courts; three tribunals (Casablanca, Rabat, Ujda and
court of appeal (Rabat).

In order to ensure "a constant and regular collaboration betwe
the Government and French colonists," the presidents of the cha
bers of commerce and agriculture of Rabat, Qnitra and Casablan
and of the mixed chambers of Marrakesh, Mazagan, Ujda, S
Meknes and Fez (whose members are elected), assemble once
month in a Council of Government, the agenda of whose sittings
always communicated a week in advance. There is a municipal co
mission in each important town (the same as above), theoretica
presided over by the Pasha, representing the Sultan, and practica
by the French chief of the municipal services. They have a cons
tative voice, except in Casablanca, where it is deliberative.

Public Instruction.—In 1916 there were 140 schools under Frer
supervision, with 470 masters and 14,834 pupils. In 1924 the scho
numbered 199 (90 French; 67 Franco-Arab; 42 Franco-Jewish a
Jewish), the masters 938 and the pupils 29,030—417 for higher
struction; 2,822 for secondary education; 23,327 for primary edu
tion; 1,029 for the technical schools and 1,435 for the evening cour
in two or three big towns. A distinction is drawn between the p
mary schools for the sons of "notables" and the other prima
schools. The teaching of housekeeping (Écoles menagères) has b
started for native girls. There are two Mussulman colleges, in Ral
and Fez, where selected pupils from the special schools for the s
of notables receive, in a course of studies of six years, higher educat
in Arabic (language and literature) and Mussulman religion and la
with the elements of French, mathematics, general geography a
practical science. Those studies are completed in the institute
higher Moroccan studies at Rabat (also open to French pupi
where Arabic literature and language are taught thoroughly, as w
as the special history and geography of Morocco, the Berber c
toms and dialects, ethnography, French and Mussulman law, a
lectures on the administrative organisation of the country. It is
seminary for officials and interpreters. There is also an importa
Sherifian scientific institute (10 laboratories) in Rabat. An ind
trial and commercial school exists at Casablanca (232 pupils) w
evening courses (360 pupils). There are official workshops (atelie
for apprentices in the principal towns, and also a few for girls (carp
making, etc.), and technical schools for Europeans in Casablar
and Ujda. A special service is in charge of the historical monumer
both Roman (Volubilis, etc.) and Moorish. Local laws, inspired
the French director of the service, protect the artistic remains in
towns, and some restorations have been undertaken. Special lo
ings and studios have been provided in the most interesting to
for European painters and architects, who can come and study
the country.

---

[1] The link is secured by the French councillor to the Sherifian Govt. (decree of May 19 1917).

[2] After they have been *immatriculated*, land properties fall under the new land laws and French tribunals.

III. ECONOMIC HISTORY

Population.—The 1921 census, completed (1924) by the latest official statistics, gives an urban population of 612,987 for French Morocco. The rural population is not really known, certain parts of the country being still outside French administration, and others very lightly administered. The estimated total is 4,410,000 inhabitants. There are three principal towns: Marrakesh (145,000), Fez (124,500), Casablanca (110,900). The next in order of importance are Meknes (38,000), Rabat (33,000) and Safi (25,800). Then come Sali (24,300), Ujda (22,200), Mazagan (22,000) and Mogador (19,500).[1]

Frenchmen numbered (1924) 51,889 (24,799 in Casablanca, 7,218 in Rabat, 4,400 in Ujda, 2,800 in Fez, 1,700 in Marrakesh, etc.); Europeans 32,320 (17,487 in Casablanca; 5,000 in Ujda, etc.). The Jews total 73,400 (in the towns, descendants of immigrants from Andalusia). There are also a few Jewish converts among the Berbers in the country. Spaniards rank first among the Europeans, Italians come next.

In 1923 (official figures) 23,473 passengers arrived at Casablanca, of whom 5,133 came to stay (3,682 Frenchmen, 532 Spaniards, 382 Italians, 63 British, etc.) Of these, 660 came for commerce, 424 as engineers, contractors or as workmen for the building trade, etc.; and 1,200 tourists visited Morocco. On the other hand, about 30,000 natives (including a certain number of Riffans) crossed over to Algeria as harvest labourers; 4,596 Moroccans went to France as labourers; 1,250 returned the same year, bringing back over 2,000,000 fr. savings.

French Colonisation and the Land Question.—At the end of 1913 French properties numbered 1,127, representing 1,073,000 ac., lying principally in the El Gharb region (north of Rabat—about 250,000 ac.); the Shawiya (south of Casablanca), the environs of Rabat and Ujda coming next. Other European properties numbered 117 (Spanish 28, Italian 39, English 20, etc.), covering 52,700 acres. Farms of less than 100 hectares (250 ac. represent 44·8 % of the total surface in European hands; large farms (over 1,250 ac.), 14·3 %. The rest (40·9 %) varies between 250 and 1,250 ac. (*colonisation moyenne*). Of the total surface, 179,000 ac. had been given away by the official colonisation system (sales), and the rest bought directly from the natives. About half the French colonists come from Algeria and Tunisia and are already familiar with local conditions.

The establishment of French power brought about a great change n economic and social conditions in agriculture as elsewhere. Both he soil and the climate are, in many parts of Morocco, far more avourable to settlement than to nomadism. The feebleness of the central native power (Maghzen) and continual intertribal strife used o render private property (*melk* lands) almost illusory. But, especially since 1919, in the pacified parts, the natives have settled on he land which was, before, "common" land (*arch*), inalienable ccording to Mussulman law and custom. It is both wise and just o reserve a part of them (it is estimated that about 5,000,000 ac. an be cultivated instead of being left for sheep grazing) for French nd other colonists, who can put them into far better value.[2] There re also maghzen and habu (religious property) lands that can be etter utilised. Land registration has been introduced in Morocco ince 1913, and 5,826 titles had been registered at the end of 1923, n which, at that date, 186,000,000 fr. had been borrowed on mortage. Natives are also beginning to register their lands.

The colonists cultivate the same crops as the natives: wheat durum principally), barley, oats, beans, etc.; the olive tree, flax or seed). There have been a few experiments in growing castor-oil eed and in cotton and hemp since the War. Orange culture in the egions of Meknes and Marrakesh is promising. Vineyards only ccupy a few hundreds of acres; and for the moment the raising of arly vegetables (so successful in Algeria) is confined to the uburbs of a few big towns for their European inhabitants. Stock ising (sheep especially) is also carried on, sometimes in association ith natives; the number of sheep was estimated in 1924 at about 0,000,000, of which 7,200,000 paid the tax tertib, and about 100,000 ere in European hands. The amelioration of the local breed, both om the point of view of the flesh and the wool,[3] is being steadily ursued; as also the study of several other important agricultural roblems in the official farms and experimental fields.

Budget.—The 1924 budget foresaw 312,629,000 fr. ordinary ceipts; of which, customs produced 83,000,000 fr.; tertib, 66,000,000; xes on consumption (sugar, tobacco, etc.), 60,000,000. The 2,442,000 fr. of expenses were principally distributed as follows: ublic debt, 62,000,000; justice and general administration, 72,000,-0; services of economic interest (public works, agriculture and commerce, etc.), 91,000,000; services of social interest (education, health, etc.), 29,000,000, etc. The total actual debt of the Protectorate amounts to 705,624,000 francs. Morocco contributed (1924) 46,000,000 fr. to the French military expenses in the country. At the end of the same year France had spent 4,271 million fr. since 1907 in Morocco. But if the ordinary garrison expenses (not special to Morocco) are deducted—2,501 million fr., or 63·6 % of the total—the total cost proper of Morocco to France represented at that date 1,431,000,000 francs.

Railways and Public Works.—The 1,300 km. of narrow gauge military railways existing in 1923 registered that year 61,620,000 kilometric-passengers and 67,750,000 kilometric-tons of merchandise. They are gradually being replaced by the standard gauge, 400 km. of which were already in operation in 1926, and which will be partly electrified when the Casablanca central power station is finished. Including the Tangier-Fez line (310 km.), the new system will have a total length of about 1,000 kilometres. The admirable phosphate region of El Boruj-Wed Zem is already linked up with the port of Casablanca, which now possesses a length of 425 metres of quays for big ships (depth 48–50 ft.) under the protection of a jetty over a mile long (2,000 metres). The other ports are Qnitra, Rabat, Fdala, Mazagan, Safi and Mogador.

The network of roads consisted (end of 1923) in 2,665 km. of principal and 577 km. of secondary roads, and 933 km. more were being constructed or projected. There existed at the same date 12,300 km. of telegraph lines. Besides the sea postal service, Casablanca is in daily postal connection by aeroplane with Toulouse, by Algeciras, Barcelona and Perpignan.

The year 1925 marked important progress in the value of Moroccan commerce: 1,754,000,000 fr. (imports, 1,189; exports, 565), as against 139,0,000,000 fr. in 1924, and 850,000,000 in 1923. Figures in tons are still more decisive.

	1923	1924	1925
Exports	339,236	815,160	982,921
Imports	448,293	426,572	569,640
Total (tons)	787,529	1,242,732	1,552,560

The great growth in exports is due to the progress in the exploitation of the magnificent phosphate beds of Wed Zem (finer than those of Tunisia): 720,000 tons exported in 1925. By far the greater part of Moroccan commerce is centred in Casablanca (1,135,600 tons, 1,082,000,000 francs). The two ports ranking next are Qnitra (138,700 tons) and Safi (90,600 tons). Fdala is last on the list. Commerce by land with Algeria (Taza-Ujda) amounted to 77,860 tons. On Jan. 1 1924 there were 615 industrial establishments in European hands in Morocco, employing 7,223 hands and 22,868 horsepower. The capital invested amounted to 273,600,000 francs. Electricity heads the list; flour-mills, slaughter houses, lime and cement factories come next. Casablanca comes first (140,000,000 fr. invested). Rabat, Marrakesh, Fez, Qnitra and Ujda rank afterwards, in the order named.

BIBLIOGRAPHY.—Official and general publications and periodicals: *Annuaire Economique et Financier* (Casablanca); *Archives Marocaines* and *Hesporis* (Rabat); *Bullétin de l'Afrique Française*, with its remarkable supplements (Paris); *La Renaissance du Maroc, Dix ans de Protectorat* (Rabat, 1922); Prosper Richard, *Le Maroc* (Paris, 1925), with an English adaptation by C. Heywood, *Morocco, Mysterious Islam*; P. III. SPANISH MOROCCO

The Spanish zone in Morocco extends over an area of 18,360 square miles. Accurate returns of the population are impossible. The civil population in the towns in 1923 was estimated at 118,305, of whom the majority were Mahommedans. Tetuan, the capital of the Protectorate, had an estimated population of 23,447 in 1923. Other towns were Melilla, 60,000; Larache, 15,430; Alcazarquivir, 12,368.

Education in Spanish Morocco is conducted under the auspices of the different creeds. Catholics, Mahommedans and Jews have their own schools. The budget of the Protectorate provides the salaries of professors at the university in Tetuan. There were 175 primary schools, of which 74 were specially for Moorish children. The total number of pupils attending the primary schools in 1923 was 24,679.

Administration.—By a royal decree of Jan. 18 1924 the direction of affairs in Spanish Morocco was entrusted to the Premier of Spain, with the exception of military matters, which were confided to the Ministry of War. The Spanish Govt. is represented in the Protectorate by the High Commissioner, who presides over the Civil Services. A royal decree of March 1925 fixed the limit of the Spanish forces in the Zone at 80,000—65,000 Europeans and 15,000 natives. The intermediary between the higher command and the Moorish troops is the officer known as the *Caid Interventor*.

---

[1] "Urbanism" was a great feature under Lyautey. If Casablanca certainly an overgrown town, the plans for the extension of the incipal towns (drawn up by M. Henri Prost) are remarkable, and refully preserve the native quarters.

[2] In Tunisia, for instance, in 1921, the 190,000 ac. cultivated in heat by Europeans produced 68,000 tons, whereas the 1,250,000 . in native hands only gave 120,000 tons. In Morocco, where a ench colonist loses 7 % of his sheep stock, a neighbouring *Kaid* will e 48 %—a case of direct observation.

[3] Wool of the *Abudia* commercial type, of the Beni Hassen, is eady of a superior quality; it is perhaps the original *merino*.

The reverse suffered by the Spanish arms in 1921 through the defection of a friendly tribe, when Gen. Silvestre was killed, precipitated a political crisis in Spain, which culminated in the proclamation of the Military Directory in Sept. 1923. The policy of the President of the Directory, Gen. Primo de Rivera, was to establish a single front, to effect which the army was withdrawn from portions of the occupied territory and a number of positions were evacuated.

Spanish subjects in the Protectorate enjoy all the civil rights recognised by the law in Spain; foreign residents enjoy the same rights subject to certain provisions. All residents, whether Spanish subjects or not, must conform with regulations relating to the police and public security. The budget for the Zone for 1924–5 was 15,607,500 pesetas. The total trade values, in pesetas, for 1922 were: imports, 4,367,401; exports, 7,080,413—a favourable trade balance of 2,713,012 pesetas. Agriculture in the Spanish Zone has made progress since 1923, and of the 330,000 hectares of land available for cultivation in the eastern zone 120,000 have been taken up for production. Lemons, oranges, olives and many cereals are grown. The *Agrupación agraria* at Alcazarquivir has inaugurated a new era of agricultural progress.

The Spanish Zone is served by three railways: Ceuta-Tetuan, Nador-Titztutin, Larache-Alcázar, with a total mileage of 90 miles. Public highways have been constructed in the central, eastern and western regions.

MOROCCO, CAMPAIGNS IN.—The colonisation of Morocco has always been attended by violent encounters with the numerous tribes inhabiting that country. Since 1910 France and Spain, the two protecting powers, have both had to contend afresh with native hostility, encouraged and assisted to some extent by agents of Germany. The following account of this aspect of Moroccan history is given under three headings, namely, I. Spanish Campaigns; II. French Campaigns; and III. Franco-Spanish Campaigns. The last deals with the combined action of France and Spain against the tribes of the Rif.

I. SPANISH CAMPAIGNS

The history of Spain in the Rif has been one of intermittent warfare ever since, at various dates in the Middle Ages, she obtained possession of and occupied her "Presidios" on this coast of North Africa—Melilla, the Zaffarin Islands (Islas Chafarinas), Alhucemas, Peñon de la Gomera and Ceuta. Confined to the narrow limits of these possessions, it was ever Spain's desire to obtain more breathing-room so as to be able to put them to a greater utility than mere penal settlements. At various periods, for instance after the Spanish Moroccan War of 1859–60, the Spanish Government had demanded and obtained some territorial expansion at Ceuta and Melilla, but the other points, rocky islands off the coast, remained at the mercy of the tribesmen of the mainland and could only with difficulty be provisioned. As was only natural the relations between the Spanish and the Rifis were difficult.

Spanish Expansion.—The loss of her colonies at the end of the 19th century caused Spain to seek compensation in Africa; and the Franco-Spanish Treaty of 1912, to which Great Britain was a consenting party, gave her the opportunity she sought. By this treaty the Spanish zone in Morocco was delimitated and Spain's hands were freed to undertake its occupation. Already in 1909 she had fought a costly campaign in the Melilla district which had left a comprehensible desire in the Spanish Army for revenge. In 1912 the occupation of various parts of the Spanish zone was begun and in that and the succeeding years Tetuan, Larache, El Qsar (Alcazar), and Arzila were reached and the neighbouring districts occupied. At the same time Spanish forces marching south and westward from Melilla succeeded in penetrating some distance into the Rif without meeting with serious resistance.

Effect of the World War.—The Spanish task was at first much facilitated by the World War, during which the Spanish zone was used by the Germans as a base of active propaganda and action against the French Protectorate. Money was lavishly distributed amongst the tribesmen for the purpose of raising Ri forces for inroads into French territory, and Rifi attention was largely withdrawn from the more imminent danger of Spanish invasion. The end of the war put a stop to this anti-French action and the Rifis, who had received from the Germans large sums of money and no small quantity of arms, turned against the Spaniards. In 1919 General Berenguer, the Spanish High Commissioner, was forced to open a campaign in the Jibala highlands which led, in the following year, to the occupation of Sishawen (Sheshuan). Raisuli, sherif and ex-brigand, whose influence amongst the tribes was great, facilitated on this occasion Spanish action.

'Abdel Krim.—Further east 'Abdel Krim, the son of a Ben Uryaghel (Ouriaghel) chief, had deserted the Spanish servic and was stirring up resistance to the Spaniards in the Rif. I 1921 a Spanish Army of nearly 20,000 men holding the country between Melilla and Alhucemas was annihilated by the Rifis This disaster, which began with the fall of the advanced post o Anual and the death of General Silvestre, leading to a subsequen panic, ended in the loss to Spain of all that had been acquire in several years of campaign and diplomacy. At least 10,00 soldiers were killed, after the perpetration upon many of them of every kind of atrocity. Melilla itself was for a time at th mercy of the tribesmen, but for some unexplained reason the did not enter the town.

These Moroccan events led to a crisis in Spain and in Sept 1923 the Constitutional Government was replaced by a Militar Directory under Gen. Primo de Rivera. The situation in Afric was serious. The outlying Spanish positions, often cut off alto gether, were threatened in every direction and the president o the directory recognised that immediate action was necessar if the Spanish garrisons and Spanish prestige were to be saved He decided upon the wise and courageous course of a genera withdrawal from the front, including the evacuation of Shishawen It was not until the autumn of 1924 that this difficult manoeuvr was accomplished, after considerable loss in men, in artiller and in arms and ammunition. New lines were occupied, passin from the immediate south of Tetuan to the frontier of the Tangie zone and thence southward to near El Qsar and the frontier o the French Protectorate. The road from Tangier to Tetuan wa preserved as a couloir, strongly guarded on both sides, throug enemy country. The evacuation by the Spaniards of thos extensive regions added not a little to 'Abdel Krim's influenc and prestige. Raisuli, ill and bedridden, was taken prisoner b the Rifis and died a few months later, a captive at Adir, 'Abde Krim's headquarters. (W. B. H.)

II. THE FRENCH CAMPAIGNS

The Fez rising which took place in Oct. 1910 (*see* MOROCCO was followed by continued trouble in the Fez-Sefru distric during the autumn of 1911. A new pretender, Hamed el Hiba occupied Marrakesh in Aug. 1912, but he was expelled in Sept and therepon fled south. In Oct. Gen. Lyautey occupie Agadir. Fighting in Western Morocco continued for som months; but this district and that of Fez were occupied by th spring of 1913, and the French concentrated their attention o Eastern Morocco. The important strategic point of Taza, whic commands communications with Algeria, was occupied in Ma 1914, Khenifra captured in June.

The World War Period.—On the outbreak of the Worl War, the French commander received telegraphic orders from th Ministers of Foreign Affairs and of War (July 27–28 1914) " reduce the occupation to the principal points on the coast," a " the fate of Morocco would be settled in Lorraine," and askin

yautey to send all available men and material to the French
ont. Lyautey immediately dispatched 37 battalions and
ther troops; but refused to evacuate the interior. The tribes
und Taza, and the Zayan in the west, promptly rose, but
e *kaids* of the Atlas and the *bashas* of Tarudant and Tiznit
the south near Agadir remained friendly, the latter keeping
l Hiba's forces in check. The Spanish zone was used by the
ermans as a basis of active propaganda and action against the
ench Protectorate. The tribesmen received lavish donations
arms and money from the Germans. Throughout 1915
d 1916 chiefs in German pay conducted a campaign along the
ad Wergha. Nevertheless, the small French force more than
ld its own. In May and June 1917 Abd el Malek was driven
om Taza. On March 24 1917 El Hiba was severely defeated
Wijan; his force was finally dispersed in the following spring.
ne Tafilelt was definitely occupied at the end of 1917. In
ug. 1918 a revolt began among the Aid Atta, which was sup-
essed by April 1919 with the help of El Glawi.

French Activity, 1918-23—After the War the French continued
eir operations, taking the offensive, now on one, now on the
her, of their four fronts: the Northern (Spanish zone; Djebala
d Rif tribes), the Berber (Central Atlas), the front of the big
ids (El Glawi, M'tongi, Goundafi) and the Southern front
ut Aissa, Tafilelt). In 1919 the 80,000 French troops were
ccessful in the Bu Dnib territory in the southeast (Jan.–March),
the Wenah (northwest) in April, in the Taza Corridor (June–
t.). In 1920 the chief activity was in the Central Atlas until
pt., when Wazzan, in the north, was taken, and operations
gan in Nov. north of Agadir. For 1921 the main operations
re again planned for the Berber front, but in Feb. the Djebalis,
aded by Kacem ben Salah and Abd el Malek, again rose unexpectedly. Though reinforced by the Beni Mestara and the Beni Mesguilda, they were put down by General Poeymirau in April. General Aubert settled the Beni Waghrain question in June, and Poeymirau once more filled up the Bekrit "pocket" in the Zayan country in the autumn. By the end of 1923 the French zone was pacified, 1923 being especially devoted to wiping out the Taza "stain" (*la tache de Taza*). The last French operations were largely dictated by the need of gaining control, for irrigation and other purposes, of the "Water Castle" of the Central Atlas. Meanwhile the anti-French subventions ceased and the Rifi, now well-armed and financed, turned against the Spaniards. (H. Br.*)

III. THE FRANCO-SPANISH CAMPAIGN

Until April 1925 the Rifi had been at war with Spain alone; but the gradual occupation by the French of the northern limits of their Protectorate, which reaches as far as the southern borders of the Rif, brought a new factor into the field.

'*Abdel Krim's Offensive.*—'Abdel Krim considered that his country was threatened by this advance and in April he launched a furious attack upon the French front to the north of the Fez-Taza-ujda road, the great highway between the Moorish capital and Algeria. Under this unexpected blow the French front collapsed. The Rifi penetrated far behind the lines, forced or persuaded the surrounding tribes to rebel and pillaged and massacred when obedience was refused. The situation became critical. For some reason the French Govt. hesitated to send the reinforcements necessary until the campaign had taken an importance which might have been avoided had more troops been at once available. Wazzan and Taza were threatened and European women and children were withdrawn to places of safety.

By the end of June, Fez, the capital, was in danger. The Sultan, in order to give confidence by his presence, arrived there in the latter days of that month. The efforts to save Fez were successful but many of the rich agricultural districts of this northern part of the French Protectorate were overrun and pillaged. Wherever it was possible the more distant military posts were evacuated, but many, with their garrisons killed, fell into the hands of the enemy with such artillery and arms and ammunition as was in them, immensely increasing the Rifis' war material. In July the French Govt. decided to send Marshal Pétain to take supreme command of the French Army, which now numbered over 160,000 men. Marshal Lyautey remained in charge of the political and administrative Government. A month was lost in the reorganisation which this new decision necessitated. Meanwhile immense quantities of material, artillery, mechanical transport, aeroplanes and all the implements of modern warfare arrived on the front.

Franco-Spanish Alliance.—Realising the common danger the French and Spanish Govts. held a conference at Madrid and drew up a programme for combined political and military action in Morocco. Monsieur Painlevé and Gen. Primo de Rivera offered peace to 'Abdel Krim on generous terms. The Rifi leader refused, demanding in return the absolute independence of the Rif. It was agreed at the conference that while the French Army should advance northward from its base the Spaniards should undertake a landing in Alhucemas Bay and thus occupy the region of Ajdir, which formed 'Abdel Krim's headquarters. On Sept. 8 and subsequent days a Spanish Army of 15,000 men was successfully disembarked while, at the same moment, French forces marched northward from their base at Taza, via Kifan. A junction was carried out at Syah between these French columns and Spanish contingents advancing westward from the Melilla district.

There is no doubt that the objective of this combined force was to reach Ajdir by land and join up with the Spanish troops which had been disembarked at Alhucemas, but the autumn rains broke and the united columns found themselves in difficulties. The tracks through this inhospitable country became quickly impassable and there was an imminent risk of isolation. The French troops retired 18 m., and all along the front winter-quarters were prepared. Pétain returned to France and Lyautey resigned. M. Steeg, who had been Minister of Justice and Governor-General of Algeria, was nominated high commissioner.

The active phase of the Franco-Spanish combined action against the Rif came to a close with the advent of winter weather and such French troops as could be spared from the front were sent to more hospitable quarters—Fez, Meknes and Rabat. The campaign had been marked by no incidents of military importance. The French had succeeded at great cost and at considerable loss of life in retaking the districts they had evacuated, but neither security nor tranquillity were assured. The mobility of the Rifis made them largely immune from the results of artillery attack, and long experience in the Spanish zone had taught them how to take cover from aerial bombardment. Their losses were thus comparatively small. The absence of all war impedimenta rendered their mobility most disconcerting to troops educated on the European battlefield. In short the methods employed by the French were in many respects quite unsuitable to this kind of colonial warfare, and the hoped-for results had not been achieved when rain put an end to the autumn campaign. The constant penetration of the French lines by groups of natives who, uniting in the rear, became formidable bands, caused constant anxiety. Convoys and posts were attacked; peaceful country was invaded and farms and villages burnt.

Rifi Activity: Winter 1925.—It had been 'Abdel Krim's desire and intention, by intense propaganda to raise rebellion amongst the Protectorate tribes further south; but although at one moment there were signs of hesitation, and even of disloyalty, amongst some of the nearer Berber tribes, the spirit of rebellion was suppressed almost before it had become apparent. It was a proof of France's admirable administration in Morocco that with the exception of the tribes which inhabited the borderlands of the Rif, and thus fell directly under Rifi influence, the rest Morocco remained loyal.

As soon as the French and Spanish troops, on the breaking the weather, withdrew to winter quarters, 'Abdel Krim bega the reorganisation of his forces. The Spanish disembarkation a Alhucemas was a heavy, but apparently only temporary, blow t his prestige, though it necessitated the abandonment of his vi lage capital of Ajdir. But he was able to withdraw to a place safety within the mountains his artillery and stores of war ma terial. Only a very few of his guns fell into the hands of th Spaniards on their landing. Moving his headquarters to Targis south of Ajdir, he set to work to prepare for a renewal of th campaign. His first action was to obtain a moral revenge for th Spanish landing at Alhucemas, and for this purpose he despatche four cannon to the mountains that overlook Tetuan, the capit of the Spanish zone and the residence of the high commissione

By almost superhuman efforts the Rifis dragged these gu over the rugged mountains to a spot within nine km. of Tetua and set them up in caves situated at least 2,000 ft. above the tow and valley. From this vantage ground they opened on Sept. 28 desultory bombardment of the capital, which was still bein continued in December. The skill with which these guns ha been mounted and could be withdrawn into the caves after ever shot protected them from the fire of the Tetuan batteries. T send an expedition to destroy them was considered unduly costly The moral effect, however, was important and a large number the civil population left the town.

Close of 1925.—In Dec. 1925 the French and Spanish armie were in comfortless and insecure winter quarters, difficult t provision, and very trying to the health of the troops. 'Abd Krim was organising his army in preparation for a continuance attacks upon his enemies during the winter and for a new cam paign in the spring of 1926, which appeared inevitable unles meanwhile a settlement by negotiation could be brought abou

Peace Negotiations: April 1926.—Early in 1926, however, th prestige which 'Abdel Krim had established over the tribes the Rif began to wane and his position was much weakened by th readiness with which various tribes contemplated the cessatio of hostilities. In these circumstances 'Abdel Krim, in the firs days of April, offered to negotiate with the Franco-Spanis Governments. An unofficial armistice came into being, and meeting of French, Spanish and Rifi delegates was arrange for the third week in April. The French and Spanish Govts reached an agreement as to the terms on which they wer prepared to negotiate for peace. (W. B. H.)

On May 30, 'Abdel Krim surrendered unconditionally at Taz to General Boichut, the French commander in Morocco. I a manifesto addressed to the Rifi tribes, M. Steeg said that hi fate would be decided by Mulai Yusef, the Sultan of Morocc The French losses during the campaign were 2,162, exclusive the casualties among native troops.

The close of the Rif campaign left some questions for solutio between France and Spain, and conversations began at once be tween M. Steeg and the Spanish high commissioner, Genera Sanjurjo. Apart from the future of the Rif itself, the two triba federations in the west, in the Djabala and the Chomara remained to be dealt with; even the French zone had not bee fully occupied. (*See* 'ABDEL KRIM.) (ED. *E. B.*)

MORRIS, EDWARD PATRICK MORRIS, 1ST BARON (1859–) Newfoundland statesman, was born at St. John's, Newfound land, May 8 1859. Educated at St. Bonaventure's Colleg and the University of Ottawa; in 1884 he was admitted a solicitor and in 1885 was called to the bar. The same year he was electe to the legislature of Newfoundland as the representative of St John's in the Liberal interest. From 1890 to 1895 he was actin attorney-general for Newfoundland, and from 1893 to 1906 wa a director of the Newfoundland Savings Bank. In 1898 Morri left the Liberal party and was leader, first of the Independen Liberals and later of the People's party (1908–19). In 1902 h became attorney-general and subsequently Minister for Justic He was knighted in 1904. In 1909 he became Prime Minister retaining this office until 1918, and representing Newfoundlan at various Imperial and other conferences. In 1913 he was made K.C.M.G., and in 1917 was a member of the Imperial War Conference. He was raised to the peerage in 1918, having been since 1911 a member of the Privy Council. Lord Morris edited an edition of the Newfoundland law reports from 1820 to 1905, usually called *Morris's Reports*.

MORRISON, GEORGE ERNEST (1862–1920), British journalist and traveller, was born at Geelong, Australia, and educated at Melbourne University. From 1882 he travelled extensively in the South Sea Islands, where he studied the Kanaka labour question; in Australia, which he crossed on foot from the Gulf of Carpentaria to Melbourne; and in New Guinea. He took his M.D. degree in 1887 and after journeys to the United States and the West Indies he worked in his medical capacity in Spain, Morocco and Australia. In 1893 he abandoned medical work and set off on extensive travels in the Far East. In 1895 he was special correspondent of *The Times* (London) in Siam and two years later became Peking correspondent of the same journal. In this capacity he visited every province and dependency in the Empire, with he exception of Tibet, and gained an intimate knowledge of men and affairs. In 1911 at the outset of the revolutionary movement n China he proclaimed his sympathy for the programme of Dr. Sun Yat-sen and the Cantonese Radicals. In 1912 after the abdiation of the Emperor he resigned his *Times* appointment and became political adviser to Yuan Shih-K'ai, president of the newly formed Chinese Republic. Dr. Morrison's published works include *An Australian in China* (1895). He died at Sidmouth, Devonshire, May 30 1920.

MORTON, LEVI PARSONS (1824–1920), American banker nd politician (*see* 18.882), died at Rhinebeck, N.Y., May 16 920.

MOSBY, JOHN SINGLETON (1833–1916), American soldier *see* 18.890), died in Washington, D.C., May 30 1916.

MOSCOW (*see*. 18.891), the capital of the Union of Socialist oviet Republics, called by the Russians Moskva, had in 1925 a opulation of 1,845,000. The great increase in population was ue to the transfer of the seat of government from Petrograd to Moscow after the Revolution. It fell during the famine period, ut increased by 716,000 from 1920 to 1924 owing to the return f many who had left the city and to the increase in the number of fficials and of traders. The natural increase (the excess of irths over deaths) is about 25,000 per annum. The records howed in 1925 270,000 persons engaged in government offices, chools, trade unions and co-operative organisations, etc., 35,000 mployees in private trading concerns, 150,000 factory and mill orkers, and about 37,000 home craft workers.

The great influx of population created a serious and dangerous ousing situation, intensified by the circumstances of the famine eriod when many wooden houses were destroyed for use as fuel, nd by the cessation of building and of ordinary repairs. In 920–1 25% of the already inadequate houses were derelict. uarters were requisitioned, and the great apartment houses of ntral Moscow were run by house committees which allotted oor space to occupants, charging only the costs of repairs, lightg, cleaning, etc. The New Economic Policy was followed by a turn to a more normal rent system. Houses were put in order, avements restored, and a considerable amount of new buildings as put in hand in 1923 and 1924. In 1912, with a population of 618,000 Moscow had 281,500 apartments; in 1925, with a poption nearing 2,000,000 she had 200,000 apartments. The presre of population led the Soviet Govt. to transfer certain comissariats to Leningrad in 1925. The streets of Moscow, diating from a common centre, have an excellent tramway sysm which makes the suburbs easily accessible; in 1925 a certain mber of English motor-buses were running. The tramways rried 394,000,000 passengers in 1925 as against 257,000,000 in 13. Part of the suburban train service is in process of electrifition. Power is supplied to Moscow from a power station burng the soft coal of the Moscow district. A new electric power tion, the largest in the U.S.S.R., which burns peat fuel, has en erected at a cost of 28,000,000 rubles, and began to supply wer to the Moscow industries in 1926. The principal industries of Moscow, textiles, engineering, food, had not recovered their pre-War output in 1925.

Moscow has always been an important trade centre, and its position in the home market became steadily more important after the establishment of the headquarters of the various state trusts in the city. The Moscow Goods Exchange, established by the Trade Commissariat registered a turnover of 2,991,000 rubles in 1924–5. It is stated that only 5 or 6% of this is private capital.

Even with the opening of private shops and the repair of streets and buildings Moscow had not recovered its former busy aspect; the general poverty of the people prevented that. Some of the former palaces of the Moscow aristocracy and merchants have been turned over for public purposes, or for the use of foreign legations and missions. Many of the principal streets have been renamed after revolutionary personages. The city still remains an important literary and artistic centre, and the Moscow theatres are still among the first in Europe in the variety and beauty of their productions.

MOSELEY, HENRY GWYN-JEFFREYS (1887–1915), British physicist, was educated at Eton and Trinity College, Oxford. As lecturer in physics in Rutherford's laboratory at Manchester University, and subsequently as John Hartling fellow, he carried out a brilliant series of researches, proving the existence of a simple relationship between the X-ray spectrum of an element and its atomic number, and establishing a new and valuable method of chemical analysis. He was killed in Gallipoli Aug. 10 1915.

MOSLER, HENRY (1841–1920), American artist (*see* 18.898), died at New York City April 21 1920.

MOSUL (Vilayet) (*see* 18.904).—This former vilayet of the Turkish Empire now forms part of 'Iraq. It includes the hivas of Mosul, Arbil, Kirkuk and Sulaimaniya making an area of 35,130 square miles. Its boundaries are Syria on the west, 'Iraq on the south and southwest, Persia on the east and on the north the disputed Brussels Line dividing it from the Bitlis vilayet. As regards the ethnographical details of the population, the estimates provided by a pre-War Turkish census and those compiled by British officials in 1921 differ widely. The total population appears to be roughly 750,000, nine-tenths of the inhabitants being Moslems. In the town of Mosul and the surrounding plain the Arabs are the predominant race; in the mountains, the Kurds. The League of Nations Commission (1925) stated that the district was inhabited by Kurds, Arabs, Christians, Turks, Yezedis and Jews in that order of importance. Upon the corn grown in the plains round Mosul a wide area extending to Lakes Vrumia and Van depends for its sustenance, while the almost impregnable mountain ranges give Mosul a strong strategic position in regard to 'Iraq. The great rivers of 'Iraq have their headwaters in Mosul, and he who is master in Mosul is also master of 'Iraq's most vital necessity, being capable of threatening the safety of the vast oil resources of 'Iraq.

By the Armistice of Mudros, hostilities were suspended between Great Britain and Turkey from midday Oct. 31 1918. Nevertheless on Nov. 3 General Cassels informed the Turkish authorities that he had been ordered to advance beyond the Armistice line and occupy the town of Mosul. This apparent violation of the Armistice terms was subsequently declared to be justified by Article 7 of the Armistice—"dans le cas où il surgirait une situation qui menacerait la sécurité des Alliés, ceux-ci auront le droit d'occuper tout point stratégique." The Turks on the other hand maintained that no such menace existed, and protested strongly against this action on the part of Great Britain. Later on further advances were made by the British forces; on Sept. 30 1924 a provisional frontier, known as the Brussels Line, was proposed by the League of Nations and accepted by both Great Britain and Turkey, pending a final settlement of the dispute. This Brussels Line was at its nearest points no less than 150 km. north of the Armistice frontier. It ran from the Hazil to the Khabur river, then across the mountains north of the valley of the Great Zab and then due east to the Persian frontier. Roughly speaking it runs on the crest of the mountains cut through by the three rivers named.

The question of the vilayet figured prominently in the discussions at the Lausanne Conference. Clause 3 of the Treaty of Lausanne provided that the dispute between Britain and Turkey should be brought before the League of Nations unless settled by agreement within nine months; the Turks had agreed to this on Lord Curzon assuring them that " the decision of the Council, upon which the Turkish Govt. will be represented, will have to be unanimous, so that no decision can be reached without your consent."

Sir Percy Cox carried on fruitless negotiations in Constantinople (May 19–June 15 1924); but the Turks refused to abate their claim to the whole of the former Mosul vilayet. In Aug. the matter came before the League, which appointed a commission to study the question. In Sept. the Turks crossed the provisional frontier and drove some 8,000 Assyrians to take refuge in 'Amadiya where they were supported by the 'Iraq Government. Thereupon at a special meeting in Brussels in Oct. the League defined a provisional frontier, the Brussels Line, which Turkey agreed to accept as a *status quo*. The Commission reached Baghdad in Jan. 1925 and reported in Aug. that the historic right was with Turkey; but suggested that Mosul should be left to Turkey if Britain intended to withdraw from 'Iraq in 1928, but assigned to 'Iraq if Britain was willing to undertake a mandate for 25 years.

Turkey contended that the League could not give a binding decision; the question was referred to the Hague Court, and was still pending when further military movements by the Turks in the neighbourhood of the Brussels Line in Sept. 1925 resulted in the violent deportation into the interior of Turkey of Christians living immediately to the north, and in some cases even to the south of the provisional frontier, while some 3,000 Chaldeans took refuge in a destitute condition in 'Iraq. The League appointed a second Commission to examine the complaints on both sides and report any violations of the frontier.

This report was presented to the League in Dec. and left no doubt as to the harshness with which the refugees had been handled by the Turks. The ruling of the Hague Court—that an arbitral decision was binding—had already been received; but the Turkish delegate refused to accept the decision of the League and withdrew. Turkey, however, renewed her proposal of a plebiscite of the Mosul population, and further offered (1) a four-nation Pact (Britain, Turkey, 'Iraq and Persia) which should guarantee the integrity and independence of 'Iraq, (2) the cession of the valuable Syale basin containing some of the oil-fields of the vilayet and the main sources of 'Iraq's irrigation. In the absence of the Turkish delegate, the League awarded Mosul to 'Iraq under certain conditions which were accepted by the British House of Commons five days later.

The inclusion of Mosul in 'Iraq was finally agreed by the treaty signed on behalf of Great Britain, 'Iraq and Turkey at Angora on June 5 1926. By this treaty Turkey accepted the Brussels line with small modifications as the frontier between Turkey and 'Iraq, the exact line to be determined by a mixed commission an the spot. A pact of security for ten years was agreed between Great Britain, Turkey and 'Iraq. Turkey enjoys a share in the royalties on Mosul oil for a period of 25 years. Subsequently an agreement was reached on the compensation to be paid for Turkish public works in the former vilayet. An exchange of notes following the treaty gave Turkey the option of capitalizing her share of the oil royalties at a present value of £500,000. This was an important event both for politics and oil. (*See* League of Nations.)

Bibliography.—*La Question de Mossoul, 1918–25* (Turkish Red Book) Proceedings 35th Session League of Nations (Constable); *Reports* of Wirsen and Laidoner Commissions (Constable); *La Question de Mossoul* (Lausanne); G. Gidel, *La Frontière entre la Turquie et l'Irak* (Paris); E. G. Mears, *Moslem Turkey;* H. C. Luke, *Mosul and its Minorities* (1925). The text of the treaty of June 5 1926 is printed on a white paper (Cmd. 2672 of 1926).

MOSUL (City) (pop. 40,000), capital of the former vilayet of Mosul (*see* 18.904), has acquired importance since the World War. On Nov. 18 1918 (that is, 19 days after the signature of the Mudros Armistice), the city was occupied by British troops.
The advent of the railway, which now reaches a point only som
70 m. distant, Sharqat, will doubtless help to revive the indus
trial prosperity of Mosul, which at present possesses practicall
no industries, not even its once famous manufacture of muslin
deriving its name from the town. The population exhibits a
amazing intermixture of races and creeds; but in the cit
of Mosul the Arabs have a clear preponderance.

Several churches of great architectural interest are foun
amongst those belonging to the various sects, Nestorians
Jacobites, Uniate Chaldeans, Syrians, Catholics (also Uniate
and that strange remnant of the Gnostics, the so-called " Chris
tians of St. John." A promising field for antiquarian researc
lies in the great mound of Nebi Junus, on the opposite bank o
the Tigris, which covers the ruins of Esar-Haddon's palace. Thi
site, hitherto closed to the excavator, may probably be rendere
more accessible under the new Government. The exploratio
of the neighbouring mound of Tell Quoyunjuk produced unde
Layard and others the well-known relics of Sennacherib'
palace now in the British Museum. See H. C. Luke, *Mosul an*
its Minorities (1925).

MOTION PICTURES (*see* 6.374c).—This article will deal, first
with the rise and development of motion pictures, second, wit
the technology of film production and the exhibition of the pic
ture and, third, with the motion pictures as a distinctive forn
of art.

I. HISTORY

While the commercial history of the motion picture cover
only 30 years, beginning in 1894–5, the screen springs from root
which reach into the unrecorded past, with the earliest effort
at the re-creation of events. This effort, guided and controlle
chiefly by the facilities and tools available, led variously to th
evolution of pantomime, sign languages, rituals, drama and lit
eratures. The motion picture, as the complete visual re-creatio
of the desired event, came as soon as adequate materials an
technology were evolved.

Early Investigation of Scientific Principles.—Scientific invest
gation leading up to the motion picture was definitely begun b
Peter Mark Rôget, secretary of the Royal Society of Grea
Britain, who in 1824 investigated the laws of vision with refe
ence to objects in motion. That year he read before the Roya
Society a paper entitled *Persistence of Vision with Regard*
Moving Objects. Several scientifically minded persons were inte
ested, including Sir John Herschel, and among them was evolve
a device consisting of a bit of cardboard bearing a picture of
bird on one side and a cage on the other, so mounted on a strin
that when the card was twirled the bird appeared in the cag

Michael Faraday followed Rôget's observations with a lon
series of experiments. On the Continent Dr. Joseph Antoin
Ferdinand Plateau, at the University of Ghent, and Dr. Simo
Ritter von Stampfer, in Vienna, engaged in experiments on th
persistence of vision. Simultaneously they arrived at an ident
cal device for viewing hand-drawn pictures representing successiv
phases of motion. The pictures were mounted in sequence on th
rim of a disc and were observed through corresponding slits
a parallel disc revolving on the same axis. This was the fir
motion-picture machine. Baron Franz von Uchatius, an Au
trian artillery officer, in 1853 combined the disc device with th
magic lantern and projected the pictures on a screen. Willia
George Horner, of Bristol, England, built a toy on the princip
of Plateau's machine, mounting pictures on the inside of
cylinder in such a manner that they could be inspected throug
slits in the opposite side of the revolving cylinder. In 1860 o
Desvignes improved upon it and patented a similar device.

The Kinematoscope.—In 1860 Coleman Sellers, of Philade
phia, a mechanical engineer, attempted to apply photograph
to the creation of motion-picture effects. He photographed pos
of motion and presented the resulting pictures on the blades
a paddle-wheel device, viewed directly by the eye. This machi
was patented in the United States as the Kinematoscope Fe
5 1861. Louis Arthur Ducos du Hauron, in France, April
1864, filed a patent application which was in effect an almo

complete anticipation of the motion picture. Ducos' ideas were all on paper; he did not achieve material results.

The Phasmatrope.—Henry Renno Heyl, of Philadelphia, on Feb. 5 1870 presented projected photographic pictures, made by the Sellers method of posing the figures for the camera, which still required time exposures. Heyl's machine was called the Phasmatrope. It carried small prints of the successive pictures, transparencies made on glass plates, mounted on the rim of a wheel which presented them, with an intermittent motion, to a beam of light cast by a magic lantern. Heyl used 6 poses, repeated 3 times, giving 18 images, or the equivalent of slightly more than one foot of modern film pictures. Photographic pro- ection had come, but the camera could not yet record rapid motion.

Rapid Motion Photographs.—In 1872 Leland Stanford, a railway magnate of California, determined to investigate the gaits f the horse. He engaged Eadweard Muybridge to endeavour o make photographs recording the postures of the horse in motion. Muybridge's first efforts, made at Sacramento, were nsuccessful, due to the inadequacy of the camera and the photo- raphic materials then available. His labours were interrupted or the time by a domestic tragedy. Meanwhile Stanford, im- atient with the unsatisfactory results, had assigned the photo- raphic problem to John D. Isaacs, a young engineer employed n the technical staff of the Central Pacific Railway. Isaacs con- rived a system using a battery of cameras with shutter controls ctuated by a series of electrical circuits. The shutter mecha- isms were improved and the speed of the photographic emulsions ncreased. His device permitted the making of the first real hotographic records of objects in rapid motion. Exposures as rief as one two-thousandths of a second were made. When Muybridge resumed activity he used the Isaacs' equipment nstalled at Palo Alto. Subsequent writings and tradition have rroneously credited the method and machinery to Muybridge.

Stanford while visiting Paris met Jean Louis Meissonier, the ainter, then engaged in a controversy with French academicians ver the postures of horses in his pictures. Meissonier found ndication in Stanford's photographs from Palo Alto and pre- ailed upon the latter to send Muybridge to France. Meissonier onfronted his critics with these pictures. He also synthesised e appearance of motion by projecting transparencies made om these pictures on a machine similar to the Heyl Phasma- ope. Muybridge renamed the machine the Zoopraxinographo- ope and hastened to Great Britain to deliver lectures. The ame suggests a relation to the similar contemporary machine vented by Émile Reynaud, a French physicist, under the name the Praxinoscope. Reynaud used hand-made pictures.

An era of motion-picture photography on glass plates followed, th slight refinement of methods but no important increase in ope. All motion-picture records, made with series of cameras, hen projected, gave the illusion of the moving object standing ll with the adjacent scenery sweeping past. Wallace Goold evison, of Brooklyn, N.Y., devised a camera which obviated is difficulty by presenting successive plates in one camera, aking all the pictures from a single point of view.

Edison Kinetoscope.—In 1887 Thomas A. Edison, of New rsey, having perfected the phonograph, wished to supplement it th an accessory device which should present an optical record gether with the sound. The first efforts recorded pictures of croscopic size in spirals upon a cylinder, after the manner of e phonograph record. Later strips of film were constructed collodion, and experiments were made with strips of heavy luloid. In Aug. 1889 samples of the first Eastman Kodak n made on a nitro-cellulose base were obtained by Edison. is material resulted in the completion of the motion-picture chine. On Oct. 6 1889 demonstrations of the Edison Kineto- ope were made in the laboratory at West Orange. It was the peep- ow device for viewing the motion pictures recorded by the ison camera, named the kinetograph. The film strips were out 50 ft. in length and an inch in width. Each photographic age occupied one-sixteenth of a foot of this film. Forty-eight posures were made to record each second of action. In the kinetoscope the pictures were viewed by transmitted light through a magnifying lens in the peep-hole of the machine Only one person at a time could view the picture.

The Edison machine was commercially presented to the public for the first time in New York, April 14 1894. Hundreds of these machines were sold in the open market, and they carried the motion picture to the principal capitals of the world. The first motion pictures made at the Edison plant were records of portions of prize-fights, fencing matches, dances and vaudeville skits. The camera was immobile and limited in its range. The pictures could record only about 15 sec. of action.

A demand then arose for a machine which would project the film pictures on a screen, making them available to a large audience. Edison demurred for commercial reasons, believing that screen showings would exhaust the novelty market too rapidly. Meanwhile experimenters in other parts of the world were engaged in the problem of combining the kinetoscope with the magic lantern to produce screen pictures. Edison held dormant the projection efforts of his own laboratories. He failed to patent his motion-picture devices in foreign countries.

The Cinématographe.—Feb. 22 1895, Woodville Latham, father of Otway and Gray Latham, kinetoscope exhibitors, demonstrated a projector using a kinetoscopic film in New York City. The device was highly imperfect and was given prematurely to the public, May 20 1895. A better projector known as the *Cinématographe* was produced by Louis and Auguste Lumière, photographic manufacturers, of Lyons, France, who were inspired by an Edison kinetoscope exhibition in Paris. They took out a French patent Feb. 13 1895, and demonstrated their machine March 22 1895 in Lyons.

The Modern Projector.—In June 1895 Thomas Armat of Washington, with whom C. Francis Jenkins was for a time associated as an experimenter, arrived at the principle of the modern projector, a device in which the film, moving intermittently, has periods of rest and illumination in large excess of the period of movement from image to image. This machine was shown to the public first in Sept. 1895 at the Cotton States Exposition at Atlanta, Georgia. In London, Robert W. Paul, maker of scientific instruments, was called upon to make duplicates of imported Edison kinetoscopes, and in sequel made a camera early in 1895 to supply the machines with film. In Feb. 1896 he demonstrated a projection machine. Several other projectors of slightly later date and less influence on the development of the art were evolved, resulting in an endless conflict of claims of priority. The new projection machines introduced the screen motion picture largely through the vaudeville theatres beginning in London and New York, and by lecture and demonstration tours in which the Lumières were especially active. The motion picture was still only a novelty.

In the autumn of 1897 the young industry in America was thrown into a complex and violent war of litigations over patents, which continued for a decade. In Europe the art long suffered disfavour as a result of the Charity Bazaar fire in Paris, May 4 1897, in which 180 French notables died. The fire was traced to the motion-picture machine.

Improvement of Films.—Films gradually attained greater length than the 50 ft. of the peep-show subjects. March 17 1897, Enoch J. Rector exposed 11,000 ft. of film photographing the Corbett-Fitzsimmons fight at Carson City, Nevada. In the autumn of that year Rich G. Hollaman, of Eden Musee in New York, staged a version of the "Passion Play" on a roof and pictured it in about 3,000 feet. Important elements of camera technique were evolved in the pictures of feats of magic made by George Melies of the Theatre Robert Houdin in Paris, involving expedients of double exposure, fade-outs, dissolves and other now familiar optical effects used in photoplay construction.

In 1903 Edwin S. Porter of the Edison studios in New York produced "The Great Train Robbery," about 800 ft. in length, which, with some latitude of interpretation, may be considered the parent photodrama. In this picture the screen achieved narration. It produced a sensation in the yet small world of the motion picture. Many similar screen narratives followed, known to the trade as “ story pictures ” to differentiate them from the mere record and novelty pictures of the earlier period.

The Nickelodeons.—“ Story pictures ” resulted quickly in the rise of the motion-picture theatre. Sporadic efforts at the operation of theatres devoted solely to the screen had appeared for several years. In Nov. 1905 Harry Davis of Pittsburgh, real-estate operator and proprietor of a stage theatre, opened a five-cent show in that city with “ The Great Train Robbery ” as the first programme. It was tremendously profitable and a wave of five-cent theatres, commonly called “ nickelodeons,” swept over the United States, with the foci of development in the polyglottic foreign labour centres of the manufacturing zones, where the universal language and art of the screen found its most eager and abundant market.

Increased demand from the screen theatres forced the picture-makers to the erection of large studios and the organisation of stock companies of actors to enable an increased output and steady flow of film. Commercial expediency resulted in a truce in the patent wars and the ultimate formation of the Motion Picture Patents Co. in New York, Dec. 18 1908. It was in effect a cross-licensing system, and included all American producers.

The standard motion picture of the period was a sensational action story of one reel in length. Pictures were rented to theatres on a quantity and age basis, a normal programme being about 28 reels a week supplying a daily change of programme of four reels.

Censorship.—The motion picture early began to encounter censorship restrictions. In 1895 the police of Atlantic City, New Jersey, forbade the exhibition of a film showing a dance, brought to the United States from Cairo. Occasional local agitations occurred in later years. In 1907 national attention was attracted to the matter, and in Nov. of that year Chicago put motion pictures under police censorship control. In New York in the same period the Children's Society prosecuted exhibitors for showing pictures of “ The Great Thaw Trial ” to audiences of young children. In Dec. 1908 New York's motion-picture theatres were ordered to be closed pending an inquiry by the mayor, with subsequent injunction litigation. The result of this controversy was a licensing system and the establishment of the National Board of Censorship by Charles Sprague Smith and others of the People's Institute, a disinterested civic organisation. This censorship body continues, in unofficial status, as the National Board of Review of Motion Pictures, to which the picture-makers voluntarily submit their films. Beginning in 1911 with Pennsylvania, a number of American states, including Kansas, Ohio, Maryland and New York, passed motion-picture censorship laws. As a sequel to the defeat of James Jeffries for the heavyweight championship of the world by John Arthur Johnson, a negro, at Reno, Nev., July 4 1910, the Sims Bill forbidding interstate traffic in prize-fight films was enacted by Congress in 1912.

Sweden established a national censorship in 1911, Spain in 1912, Italy in 1913–4 and France in 1916. Russia and Japan exercise film censorships. Canada has various provincial censorships. In Great Britain the Cinematograph Exhibitors' Assn. established a censorship, with the approval of the Home Secretary, following the Cinematograph Act of 1909 which put screen theatres under licence, and in 1920 made submission of pictures to the Board of Censors compulsory for members.

The direct influence of censorships upon motion pictures has been on the whole slight as compared with the extent of the agitation. As internal standards of the art have improved, censorship movements have tended to lose vigour.

Development of Stage-craft.—In 1908 D. W. Griffith, an actor from the stage, entered the service of the American Biograph Co. in New York, as a writer of scenarios, and in the ensuing four years had an important influence in the development of the art of screen narration. He wove the facilities of the camera and its effects of manipulation, such as close-ups, dissolves, fadeouts and the like, into the syntax of screen story-telling. In 1909 Gladys Smith, a child actress from the melodrama stage, now known as Mary Pickford, was employed by Griffith.

By 1911 a tendency to increase the scope of the picture beyond its orthodox one-reel length of 1,000 ft. began to appear, notab through the importation of some pretentious European effort among them Homer's “ Odyssey ” and “ The Fall of Troy A kindred American effort was made with a like saga in “ T Life of Buffalo Bill,” pictured in three reels. In 1912 Adol Zukor, a New York motion-picture exhibitor, in alliance wi Edwin S. Porter, Daniel Frohman and others, imported “ Que Elizabeth,” a four-reel picture with Sarah Bernhardt in the tit rôle. This picture, made by Louis Mercanton of Paris, was t forerunner of a new era of longer and more pretentious multip reel dramas, known in the trade as “ features,” to differentia them from the one-reel programme pictures of the nickelodeon George Kleine, a member of the Patents Co. group, in th period imported and exploited with sensational success Italian production of “ Quo Vadis.” In the next few years t “ feature ” movement remade the screen industry and increase the screen audience. The motion picture now became a re competitor of the drama of the stage.

Picture Theatres.—The first large and pretentious screen the tres arose in California and Australia because there the film a shipped in a can, could overcome the obstacles of geographic remoteness. In 1914 with the opening of the Strand Theatr on Broadway in New York, a new order of film presentation a showmanship appeared. Late in 1913 Charles Spencer Chapli a British actor and pantomimist, was employed in Californ for Keystone comedies under the direction of Michael Sinnot better known as Mack Sennett, founder of the slapstick scho of screen comedy. Chaplin's extraordinary ability made hi world-famous within a few months. In 1916 he was employed John R. Freuler of the Mutual Film Corp. at $670,000 a yea Chaplin with other major stars, including Miss Pickford a Douglas Fairbanks, outgrew pay-rolls and presently becan independent producers. D. W. Griffith in 1915 presented “ T Birth of a Nation,” a tale of the American South of Reconstru tion days, based on *The Clansman*, a novel by the Rev. Thoma Dixon, and again a new standard of screen narration and spect cle presentation was set.

American Dominance.—The cessation of production activiti in Great Britain and on the continent of Europe resulting fro the outbreak of the World War left the screen art and indust almost entirely to America, where it developed intensively wi an increasingly War-prosperous public. The post-Armisti period found the American film industry with a 90% dominati of the world market, with the corporation interests of the indu try extending themselves in terms of theatre control in the mo important foreign fields, including France, Germany, Englar and the Far East.

The prestige value acquired by pictures shown in the metr politan theatres of the Strand type early led the picture-make to the acquisition of theatres for “ Broadway first runs,” exten ing presently into key cities in all parts of the United State Competitive results led in turn to the acquisition of chains theatres, pooling booking power and taking box-office profi direct. This development found its most marked expression the formation of Public Theatres, Inc., in New York, a federati of the theatre interests of Balaban & Katz of Chicago and tho of the Famous Players-Lasky Corporation, headed by Adol Zukor, which is credited with control of approximately 800 th atres in the United States. The motion-picture industry, li other industries, as a whole tends toward vertical trust form tions, beginning with the plays and novels and ending with t screen and theatre box office. A group of three major corpor tions dominates the world industry.

Organisation of Trade Interests.—The early era of violent co petition found those engaged in the industry slow to recogni a common interest. The first efforts in this direction were e pressed in the formation of the Motion Picture Board of Tra in New York in 1915, followed two years later by the Nation Assn. of the Motion Picture Industry; this soon lost pow within the industry and status with the public. Growing abus of the trade, involving credits and contracts, salacious produ tions, destructive competitive selling and the like, together wi a series of disastrous scandals involving allegations of grave misconduct on the part of important screen figures and executives, led at last to the formation (March 5 1922) of the Motion Picture Producers and Distributors of America, Inc., headed by Will H. Hays, who resigned as Postmaster-General of the United States to take the post. The Hays organisation is in effect a trade association with broad powers which affect merchandising practice, selection of photoplay subjects, international trade policies and public relations in general, with special attention to problems of taxation and censorship. Its activities have exerted a marked effect in improving the status of the motion picture in the public mind and the clarification of internal problems. A minority organisation, opposed to the Hays organisation, was formed under the name of the Independent Motion Picture Assn. of America with I. E. Chadwick as president.

Economic Effects.—A new international phase of the motion picture began to be apparent in 1925 with the discovery that American control of the screen with its presentation of the fashions and equipments of American life was exerting an important influence on world trade in fields as varied as the adoption of American shoes in France and American motor-cars in Java. Various national agitations followed, marked by parliamentary debates and proposals for embargoes, tariffs and ratio laws governing importation of the American screen product, all calculated to encourage indigenous screen industries. Great Britain, Germany, France and Italy, were the countries most concerned.

To meet this condition American producing interests showed a tendency to internationalise their productions both by the importation of foreign stars and directors and by the making of pictures for the world with American stars working on foreign locations. It was planned in this way to evade the quota and ratio restrictions in other countries, while still retaining the American market. With this development a readjustment of picture values began. From the beginning of the World War, for a period of nearly 10 years it was the accepted basis of film calculations that the United States market represented 80% of the value of a picture. With the economic readustments of Europe a new world-market for the screen developed with the prospect that the foreign rights of a picture might ultimately equal the domestic American value.

Trade Figures.—In 1925 it was estimated that there were in he whole world 50,000 screen theatres, of which 20,000 were in he United States. Statistics prepared under the auspices of the Hays organisation gave, 1924:—

Total number of persons permanently employed	300,000
Average number of feature pictures produced yearly	700
Admissions paid annually at theatres	$500,000,000
Salaries and wages at studios, annually	75,000,000
Annual advertising expenditure in newspapers and magazines	5,000,000
Expenditure for posters, photos and like accessories of advertising	7,000,000

Few foreign productions have proved successful in the Amerian market. In 1922 a total of 425 foreign features were offered he American trade, but only six were accepted. The American uccess of a European film has always been followed immediately y American acquisition of the star and director concerned, as n the adoption of Pola Negri as an American star following her uccess in the German-made film "Du Barry," retitled "Pason" in the United States.

A steady increase in the working life of motion pictures has haracterised the evolution of the art, from the days of the nickeldeon theatres, with their programmes of single-reel pictures hanged daily, to the feature period where in typical theatres in rge centres week runs and more were given to a single picture. n the nickelodeon period films were sold according to their age, epreciating in value day by day for 30 days, after which they ere classed as "commercial" and rented at as low as 50 cents reel a day. Under present conditions theatre runs are often r months, and the working life of a picture may continue several ears. "The Birth of a Nation" continues with an earning ower more than 10 years after initial presentation.

Present Policy.—Production policy, long dominated by nickelodeon influences, tends away from programme or volume production toward the treatment of each picture as an individual enterprise, separately produced and individually exploited, first as a "road show" following metropolitan presentations in New York, London and Paris, after the pattern of stage-play practice, with subsequent "release" for general distribution to screen theatres, as in the instances of "The Covered Wagon" and "The Ten Commandments."

The motion picture which began in 1894 as peep-shows in films 50 ft. long costing $25 each has reached the length of a full evening's entertainment of perhaps 12,000 ft. of film, with costs ranging into the millions.

Technological Improvements.—Technological developments in the art of the motion picture have added little save refinement to the product since the years of invention. Edison produced so-called talking pictures as early as 1895 with a synchronised peep-show and phonograph. Various devices have appeared periodically since, but with no evidence of public interest. Stereoscopic motion pictures were produced in the first decade of the screen and several systems of producing the steroscopic result have been achieved, all entailing the use of a viewing device which limits the effect and appeal. Coloured motion-picture processes were begun in the Edison plant in 1896 with hand-coloured prints. Various artificial tinting processes have been evolved, the most successful being the Pathé stencil colour method used in France. Natural colour photographic researches for the motion picture were begun in England by Edward Turner, under the patronage of Charles Urban. Turner died in the midst of his labours and the work was carried on by Urban and G. Albert Smith, of Brighton, resulting in kinemacolor, presented in 1910. Kinemacolor pictures used a two-colour process of recording through filters and reproduced by projection through corresponding filters, the process resulting in a screen synthesis of the colours. More recent processes, notably Prizma, evolved by William Van Doren Kelley, and the Technicolor process which now dominates colour work for the screen, translate the camera's colour record into pigments and tones embodied directly in the film, making it available in any standard projection machine.

The use of panchromatised negative film, which is sensitive to a greater range of colour and tonal gradation than ordinary film stock, has markedly increased, thereby improving photographic quality on the screen. Also especially sensitised film reacting only to the infra-red rays of the spectrum became available in 1925, enabling various special manipulations, important among them the production of "night effects" by daylight.

The cost of making motion-picture positives for projection has decreased with lowered cost of raw film and the development of machine-finishing processes replacing costly hand labour until prints in 1926 cost approximately one-half the production price of the early years. An increased use of motion-picture films outside the amusement field for general commercial purposes and in the home tends to follow this development.

II. TECHNOLOGY

Motion-picture work is technically a branch of photography. The general principles which cover the production of photographic images therefore apply to it, and the article on Photography should be consulted. The manufacture of the film is dealt with under Photography.

The Film.—The film is supplied in rolls 35 mm. (1·38 in.) wide and 200–400 ft. long in the case of the negative films, which is used in cameras. The positive film, on which the prints are made, is frequently supplied in rolls 1,000 ft. in length in order to diminish the necessity for making joins. Negative film is generally supplied in two speeds, known as *Par-speed* and *Super-speed*, while a variety, sensitised by means of dyes, is known as *panchromatic* film. On the edge of the film are perforations by means of which it is moved through the apparatus, and the exact dimensions of the film and of the perforations are very carefully standardised. Fig. 1 shows the standards adopted by the American Society of Motion Picture Engineers.

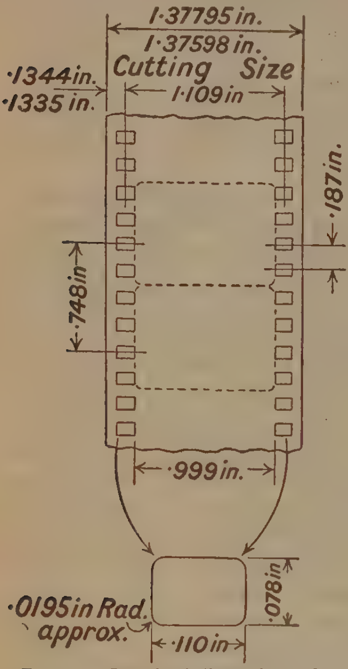

FIG. 1.—Standard dimensions of 35 mm. film. Specifications, with tolerances, allowed for cutting and perforating standard motion picture positive film.

The Camera.—The motion-picture camera (fig. 2) is arranged to move the film step by step through the *gate*, in which it is exposed to the light coming through the lens, the intermittent movement being accomplished usually by means of a claw, which is operated by a cam. The commonest form uses a triangular cam known as the *Lumière* cam because of its introduction by A. and L. Lumière of Lyons, France. By means of a sprocket, the film is fed continuously from the magazine in which it is held to the claw, and after passage through the gate is wound on to another magazine by the same or a second sprocket. Between the lens and the gate there is fitted a rotating shutter which protects the film from the light while it is being pulled down by the claw and then exposes it while it is stationary.

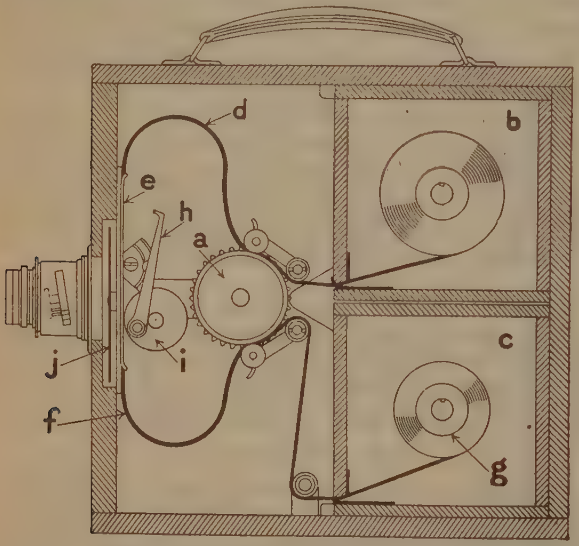

FIG. 2.—Diagram of motion picture camera, and Lumière cam. *a.* sprocket; *b.* upper film magazine. *c.* take-up magazine; *d.* unwind loop; *e.* film gate; *f.* lower loop; *g.* take-up (driven by belt); *h.* pull down claw; *i.* crank (operating pull down claw); *j.* shutter.

Lenses.—The lenses used on motion-picture cameras are of short focus and large aperture, the general focal length being 50 mm. (1·97 in.), with a relative aperture of f/3·5. Not infrequently apertures approximating f/2 are used. The operator ca thus control his exposure by adjusting both the opening of th shutter and the aperture of the lens. By using these lenses th pictures are taken at a uniform speed of 16 pictures a secon so that if the shutter opening is 180°, the exposure of each fram is $\frac{1}{32}$ of a second.

Development.—After exposure the negative film is develope each scene being usually treated separately so that the best po sible results can be obtained. It is customary to cut a shor length from the end of the scene, which is purposely made to long, and to develop this by trial. The film is then wound on rack and developed for the time which has been found bes In this way exposures corresponding to different contrasts i the subject may be developed to give uniform negatives. Th racks on which the film is developed are of the type shown i fig. 3. The development is carried out in deep tanks, the film being moved carefully in order to reduce possible marks to minimum and prevent air bubbles remaining on the film. Th fixing, washing and drying of the negatives are carried on wit the greatest care, since they are extremely valuable owing t the cost of the production and must be preserved for man years. It is usual to use two cameras for each scene.

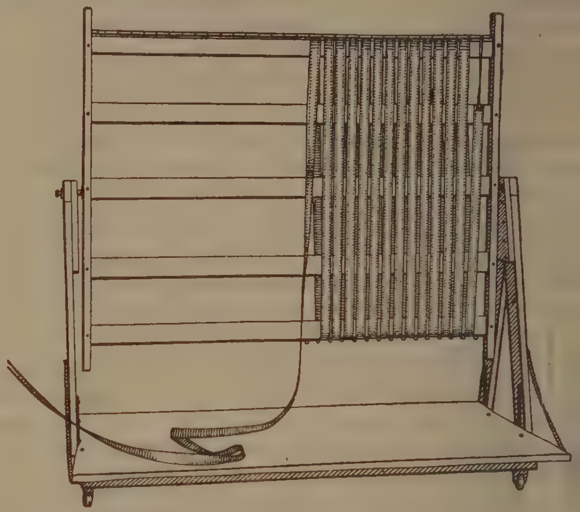

FIG. 3.—Developing racks. Wooden rack with the film being woun on it between the separator pins.

Printing.—After development a first print is made from the negative. These first prints, known as *rushes*, are viewed as soon as possible so that any scenes that have to be remedied can be retaken at once. The negatives are then assembled and a first print is made which is passed over to the producing company to be *cut* and assembled in a form corresponding to the finished picture.

The printing of the negative is performed on a printer which may take one of two forms: in one, the two films are moved intermittently through a gate just as in the camera, the positive film being printed through the negative by means of

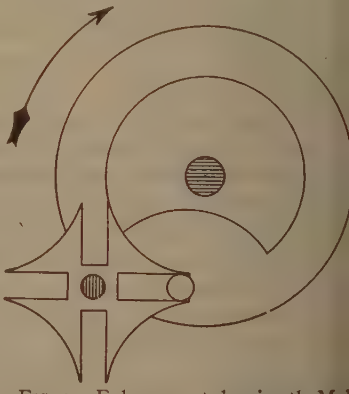

FIG. 4.—Enlargement showing the Mal tese cross movement. The continuousl moving wheel pulls the cross through 90 when the pin on the wheel enters the slo on the cross. The cross is attached to sprocket, over which the film passes and as this sprocket moves intermittent ly it pulls the film down in the gate.

light which is cut off by a shutter while the films are being moved. In the other form of printer, the negative and print are moved continuously past a narrow opening and are printed in contact while moving. In both forms it is necessary that the intensity of the printing light should be modified from scene to scene according to the density of the negative. To effect this, a chart is made showing the exposures which it is necessary to give to each scene, and the negative is notched so that as the notches come into place in the gate they will operate a contact mechanism which, acting through a solenoid system, will change the intensity of the printing lamp. Sometimes these changes are produced by the operator.

Automatic Development.—The positive film can be developed in the same way as the negative, being wound on racks for this purpose, but in modern practice it is more usual to develop it on an automatic machine, of which there are several types. In one the film passes through a number of tubes in which it travels from the top to the bottom and then up again, tubes being assigned in succession to the operations of developing, fixing, rinsing and washing, after which the film passes through a drying cabinet, from which it emerges ready for projection. In another form of continuous machine, tanks are used in place of the tubes, the film travelling in a spiral through the tanks. These continuous machines have a great capacity, it being quite usual for a machine to process as much as 20,000 ft. a day. Machines are generally erected in batteries.

After processing, the film is usually treated with wax or other lubricant to facilitate its passage through the projector. Much of the film used is made upon tinted base, the colour being applied to the base during its manufacture. This use of tinted base has supplanted the older method of dyeing the finished print, partly because it was difficult to apply the dye evenly and partly because many of the dyes used made the gelatine brittle. Not infrequently also the image is toned by different processes, so that by a combination of tinting and toning very pleasing results can be obtained upon the screen. A small proportion of film is coloured either by hand or by the use of stencilling machines, while a growing amount is produced by the processes of natural colour photography (*see* PHOTOGRAPHY).

Projection Machines.—The projection machines are essentially of the same type as the camera; that is, they evolve an intermittent movement of the film during which the light is cut off by a shutter, but this intermittent movement is usually accomplished by means of what is known as the Maltese cross or Geneva movement (fig. 4). This moves intermittently when the operating wheel carrying the pin which enters the cross is moved continuously, and the movement has the advantage over the claw and cam system that it is very robust and can be made to work immersed in oil. The shutter has three blades, only one of which is used to cut off the light during movement of the film, the other two interrupting the light while the film is still and thus diminishing the flicker seen on the screen.

Sources of Light.—The light sources used for projection are chiefly arc lamps. In modern theatres either high intensity arcs having carbons loaded with chemicals are used or mirror arcs in which the crater of the arc is turned away from the gate and the light from it is thrown forward by a large concave reflector. For projection at a short distance or with small screens good results are obtained by the use of high intensity incandescent lamps. The projectors are installed in a special projection-room fitted with ports through which the light beams are thrown and with arrangements for protection against fire. A great deal of work has been done on continuous projectors in which the film moves through the gate continuously and the image is kept stationary upon the screen by means of some optical system of rectification, such as a rotating ring of lenses which compensate for the movement of the film or a prism or mirror which holds the image still. These machines have not come into general use though some of them appear to be satisfactory mechanically.

After projection the film must be rewound and should be examined carefully and all damaged portions or weak places repaired. (C. E. K. M.)

III. THE MOTION PICTURE AS ART

From a toy, the motion picture developed into an industry in accordance with two major principles: the scientific, leading to perfection of the instrument; and the commercial, tending to the maximum of financial return in the shortest possible time. There was little energy to spare for the consideration of the third, the aesthetic, principle. The two preceding divisions of this survey have discussed those phases of the motion picture which created it and made it popular. It is the function of this third section to deal more with possibilities than with actualities; what the motion picture can become, artistically, being of far greater significance than what it is.

Natural Potentiality.—A logical critic, observing the machinery in complete ignorance of its history, would say that the name itself, especially in the common form of "moving pictures," told nearly the whole story; a camera taking pictures and a projector giving to those pictures the sense of action—movement governed by light. Assuming that the result was to be an art, this critic would hold essential the independence of the motion picture; just as music cannot always be "incidental music" or painting only illustration, the motion picture would have to develop a separate existence, drawing inspiration, perhaps, from the other arts, but fundamentally independent. It would share with painting its communication through the eye; with sculpture its power to create forms; with the dance the interest of movement. These three relations, it is understood, derive from the nature of the instrument rather than from any use to which the instrument may be put; they do not imply that the motion picture must be sculptural, pictorial or choreographic; only that it may be all of these without violence to its inner nature. They do imply as the essence of the picture that it must be all visual: the use of light and movement in the creation of visual images is the essence of the motion picture as an art form.

The Value of the "Absolute" Film.—Thirty years after the birth of the motion picture this essence is the goal of a few experimenters, chiefly in France and Germany. Theorists and experts are trying to create the absolute film, as far removed from the commercial film as a fugue of Bach is from "Il Trovatore" or a cubist painting from "The Doctor." The variation in rapidity as groups of inanimate objects or forms are shown in movement is calculated, in these experimental films, to produce a psychological effect; the relations between geometric figures, changing their proportions, fading into and displacing each other—abstract visual effects—intend the same. In the reel made by Fernand Léger and Dudley Murphy (1924) the most effective portion, emotionally, was that showing a woman carrying a burden up hill; at the final moment, as she reached the crest, the scene shifted back again to the bottom of the hill, and this was repeated again and again. There was no suggestion of narrative; the effect was purely kinematographic: but it was notable that the presence of a human figure more readily evoked emotion than any pure relation of forms. Yet there can be no doubt that the absolute film, abstract to the last degree, like music without melodic interest or like abstract painting, is a legitimate end for the motion picture. It is, in fact, the only goal so far suggested which proposes to utilise the instrument in all of its capacities and does violence to none; it is also the only one which makes proper use of the science, and is unaffected by the industry, of the motion picture.[1]

If between the absolute and the commercial, there should occur a third type, the art film, the absolute film will have the function of annulling the errors made necessary by commercial exploitation, the first error being a misconception of the nature of the instrument itself. The machinery of the motion picture was quite properly accepted as a supremely credible record of the actual; scenes, events, phenomena, were made visible and the screen became an aid to education, an invaluable record of history, and even an instrument of discovery in the natural sciences. It was put into the service of phenomenal truth, and functioned perfectly.

---

[1] The abstract film created by Comte Etienne de Beaumont and his collaborators lacked "human interest" entirely, but managed perfectly to convey emotions. Changing shapes, changing speeds, and objects seen out of their normal relations, gave both thrill and beauty to *A quoi rêvent les jeunes fille.* It is notable that these, the advance guard of films in one direction, are psychologically very close to the early melodrama; so more obviously is "Caligari." Speed is substituted for pursuit, and so on, the abstract for the specific, but the appeal to the eye is essentially the same.

It was only when this service, in all its perfection, was employed in place of the imagination, in the domain of art, that it became a disservice. The motion picture always transposes its material, either mechanically, as a phonograph does, or imaginatively, as an artist does. The impressive fact that the camera could reproduce the actual, led to its use, almost from the start, as an instrument of photographic realism, against creativeness. This was natural in a civilisation devoted largely to mechanical progress and in a country negligent of the imaginative arts; but it neglected a prime value in the instrument itself, to wit, its capacity to transpose, to distort, to displace the object upon which its eye was trained. The motion picture was, in its very beginnings, used by magicians as a new trick, a new way to create " illusion." Almost at once, however, this use was abandoned; the real magic of the picture was suggested—and forgotten.

Persuasiveness, a Prime Quality.—The power of the picture lay in its exceptional persuasiveness. It gave its spectators the primary pleasure wrongly called recognition—the ordinary sense of identifying known things presented without disguise. The actual pleasure of recognition which implies that the artist has rendered, and the spectator penetrated to, an object is one of the qualities we associate with the arts; and these, lacking mechanical perfection, fail, if they ever try, exactly to reproduce the object. The motion-picture machinery comes close to this perfection in reproducing, and the response of the spectator was a natural consequence. " This is so " was followed by " this must be so " when the motion picture took its decisive step and, by false analogy, entered into rivalry and collaboration with the theatre.

The Place of " Story."—In the absolute film, " story " is anathema; in the commercial film it is everything; the art film can only ask that the story be appropriate to the instrument and be rendered entirely by the instrument. When, as early as 1908, the French Academy and the *Comédie française* collaborated for the screen, it was in the sense of filming an actual stage production; later the idea of famous players (stage actors) in famous plays became the basis of the organisation now pre-eminent in the manufacture of commercial films. Materials consecrated by public approval were taken over with almost complete disregard of their suitability to the new medium and the motion picture became an illustrated supplement to novels and plays. Acting, a form of expression adapted to the stage, using gesture in direct relation to the spoken word, was reproduced with slight modification, in the soundless medium of the film. An acted plot became the accepted definition of the moving picture—the fusion of two borrowed elements in a crucible which was itself, if one were aware of it, a magic cauldron.

These acted plots remain in 1926 the chief interest of most producers, although the close relation between stage and screen has been interrupted. The motion picture had so much vitality that in spite of the ignorance of its masters it asserted itself. The famous players (none of whom was a player specifically for the screen) failed and an obscure actress, without developing a real screen technique, yet more naturally adaptable to the screen by reason of her meagre experience of the stage, became a world's favourite: Mary Pickford. At the same time the melodrama, the thriller, the spectacle and the slapstick comedy all succeeded; in a small way the motion picture began to develop its own resources. It is this process which at present holds the greatest promise; and makes one regret that the lapse into association with the stage should so irremediably have left its mark on the motion picture in the form of scenario and acting.

Importance of Movement.—The melodrama and the thriller were important because, whatever their story, they expressed it all in movement, rather than in gesture, facial expression or subtitles. The scenarios were such as needed movement, utilising the screen's capacity to present simultaneous parallel activities, bringing them together in climax. The formula was lacking i adaptability, the material was intellectually contemptible; bu the expression was completely kinematographic, not literary not theatrical. This was true also in the spectacle films. Th difference between the poetic beauties of " Cabiria " (on a scena rio by Gabriele d'Annunzio) and the non-literary, kinemato graphic excellence of " The Birth of a Nation " (which wa adapted with exceptional propriety from a bad novel) is marked In the latter (1915) D. W. Griffith exploited the characteristi quality of the American spectacle film; its use of the melodra matic element of suspense in direct connection with the spectacl itself. The " last minute rescue " has always been well manage by American directors, generally by subdividing it into parts— the victims, the attacker, the rescuers—and alternating thes in scenes of accelerating rhythm. This is " good movie " an distinguishes the American spectacle from the German, whic often handles masses better, creates the sense of multitudes o expanse with none of the gross lavishness of second-rate Ameri can directors, but lacks excitement proportionate to its duratio and scope. The spectacle had little to learn from the stage; fron fiction (specifically from Dickens, if one accept the Griffit version) came alternating sequences, cutbacks and other device for keeping several incidents simultaneously in development.

From the still camera came the close-up, an unhappy devic not only because of its inherent ugliness, but because it definitely breaks the precious continuity of a picture, whereas the othe devices, even the subtitle, only suspend continuity and allow interest to remain cumulative.

Economy and Effect.—It was in the thriller and the melodram that the American moving picture learned also to unroll its plo succinctly. Padding is common enough; but no one comparing the average American and the average European film can fail t note that, when they want to, American directors are able t present their effects with superior conciseness and economy There is also, in American films, an appreciable working up t climax and, their chief virtue, a neatness of execution, in which phrase may be included a multitude of technical devices, cleverness in general methods, discovery of settings which lend themselves to dramatic action, expertness in camera work, absolute clarity of the projected film, ingenuity, inventiveness. Even in their sum these qualities fall short of the meanest artistic stature they are good qualities none the less. They were, or most o them, inherent in the silly Westerns and serials of the picture's earliest day.

The Right Road.—It is the writer's belief that the first halting steps of the motion picture were along the proper, the kinematographic, road from which it has since been diverted, to which it must return, enriched by experience, if it is to have a future. Another early type fortifies this belief: the slapstick. It is no accident that the one figure in the pictures to which some degree of immortality is universally accorded should have come from slapstick: Charlie Chaplin. These comedies, especially in their beginnings, were close to the type of the *commedia dell'arte,* they were almost all improvised before the camera. In them developed a type of playing which was purely kinematographic, and could be related to the stage only by way of American burlesque. Slapstick was remarkable also because it instantly saw the motion picture as a medium for fantasy, grotesque no doubt, but in essence fantastic. The properties of the physical world, all reality, were annihilated by the tricks of the camera for specific comic effect; retarded and accelerated motion, the repertory of the stopped camera, all suspended the mind of the spectator, as a pun might or a paradox, between the intellectual certainty that a thing is impossible and the visual certainty—it is here that the credibility of the camera becomes significant—that it has just happened. The thriller employed what was hazardous or difficult; slapstick brought to the film the impossible and the unreal. Fantasy appeared elsewhere as dream and as fairy-tale, with no impropriety but, except in rare instances (Crainquebille among them), without imagination. In slapstick, fantasy was built out of the elements of common life and flourished with extraordinary imaginative vigour. Whether the material was worthy of this treatment has been debated; to some observers slapstick shows an honest vulgarity far more endearing than the pretentiousness, the intellectual fatuity, the errors of taste, the bad manners of its more serious counterparts in the films.

Dangers of Realism.—The use of indifferent materials in the usual American feature film was made doubly dangerous by the pedestrian realism of the direction. The motion picture seemed in 1920 to be destined forever to photography, to lack all bearing on created art. (It is worth noting that except for scientific purposes the motion picture cannot be exact; absolute fidelity in photographing "He walked six miles before breakfast" would result in unbearable tedium.) Fore-shortening, indirect suggestion, the creation of images capable of evoking the desired emotion—all the processes of the arts must find their counterparts in the films and will be governed, after the ruling direction of the mechanism, by the physiology of the eye, and by the psychology of attention; that is, if the picture is an art in the old sense. There are critics, wholly favourable to the motion picture, who consider that its real future is in developing outside of the sphere of the fine arts and in conscious hostility to their precepts. The break in 1920 came with the exportation of a German film, the famous "Cabinet of Doctor Caligari."

Without immediate effect on public or producers, this film is memorable because of its effect on the critics; it may be said that "Caligari" created motion-picture criticism in England and America. French critics hold it in low esteem because of its elaborate scenario; yet even they allow its chief virtues: that it worked chiefly through the camera (although the subtitles in the American presentation were lengthy and frequent) and broke entirely with realism on the screen. The change was marked by the use of cubist and expressionist settings in place of actual built or discovered "locations." The settings were psychologically correct for the story; the picture was perfect in the moments when its chief players, Conrad Veidt and Werner Kraus, so played before the distorted backgrounds as to give the whole picture a logical, complete, acceptable rhythm of its own, a life of its own, recognisable not as reality, but as a possible reality, an escape from or transposition of reality. "Caligari" was notable because it was artistically right in showing that the picture was most effective when it was not photographic; it was psychologically right because it brought the imagination of the spectator into play. It has been shown in Europe for six years (and finally made into play); it is in no sense a failure. That it failed in America may be ascribed, by critics hostile to the naturalistic film, to the stultification of popular taste in the preceding 10 years of the film's wanderings on the wrong road. "Caligari" means that the motion picture must be created, not photographed; painted backgrounds are incidental.

Five years later another German film, superficially less striking, claimed universal attention: "The Last Laugh" ("The Last Man" is another name for it). Films without subtitles had appeared before; the distinction of this one was that everything the picture had to say, and it said some subtle things, was said by means of the camera. What is more, the correlation of scenes was perfect, the separate sequences held together, and needed no connection or explanation. The American director, aware of American distaste for long series of pictures without subtitles, is prone to let his story hang loosely, trusting to its titles to draw it together. The slower-moving Scandinavian and German films are closely knitted in the sequences of the picture and can give psychological explanations which the faster American films skip or explain in words.

Importance of Imagination.—The artistic film will be characterised by imagination and will express itself visually, *i.e.*, through the camera. Ingenuity has already used the camera, notably in the excellent trick films presented for the trick alone; the news pictures have also learned kinematographic methods well. Creation has lagged behind, partly because there have been so many temporarily acceptable substitutes. The imaginative communication of emotions in "The Last Laugh" may prove a failure; but a few thousand dollars invested in a railway wreck is likely to make a picture a success. The director, at present the most interesting figure in the motion picture, has always known this. The future of the picture depends upon his capacity to free himself from tricks, from detailed scenarios, bad acting, "screen personalities" and other misfortunes. More, it depends upon his intelligence to see that the completed film must be a unit, not a series of separate scenes which a scenario-writer has invented and an editor-cutter will piece together for a title-writer to render reasonable as a plot. The motion picture conceived as a unit will have internal growth, development, rhythm; the relation between its parts and between the durations of its parts will have purpose; the bearing of the parts on the whole will be effective; the picture will have both style and form. At present few directors have manners so definite that their work can be identified without recourse to their tricks. Actual style, a personal way of expressing something experienced or observed, is almost entirely lacking, and that a picture as a whole should have form is a heresy still unheard in Hollywood.

Style and Form.—The future of the picture as an art depends, nevertheless, on the growth of elements of style and form, such as, with natural differences, distinguish the other arts: economy of means, sobriety, seriousness of purpose—all the other tests for an artistic creation are certain to vary with the individual artist, but the moving picture will not begin to be an art until it is conceived as the communication of a precise emotion or experience (communication by a group of artists or by a director through a group of interpreters of his vision). The expression of such a personal vision in a highly personal style distinguishes Chaplin as actor; a bluntness of perception, an imperfect sense of form, make him less than supreme as a director. But one looks vainly elsewhere for more than the beginnings of his qualities. Perhaps a half-dozen directors in America, twice as many in all Europe, seem at moments to approach the question of the motion picture as an art, but none offers a solution to it.

Except for striving for the film which shall have the illusion of depth, science seems satisfied with the motion picture. (The twin mistakes—the film synchronised with a talking-machine and the colour-film—may be perfected; but as each relieves the director of an obligation, instead of compelling him to fulfil one, they are not necessary developments of the film as art.) At the same time, the film as commerce may become stabilised; the pioneer days when companies were hastily organised to make the most of a nine days' wonder are over. With these two effective agencies reduced to secondary places, the moving picture as an art may flourish. So long as it remains a popular art, it will require novelty. Its greatest novelty, at the moment, must be an artistic one. (G. SE.)

MOTORING.—From 1910 onwards the development of all types of motor vehicles was wonderfully rapid. In 1911–2 the charabanc, the motor omnibus and the smaller passenger and goods van, used in town and country alike, began to make an impression on the travelling public of Great Britain, and though before the outbreak of the World War such traffic was of small dimensions compared with its present volume, the tramways and railways had already begun to feel the competition. The public at once showed its preference for the new method of locomotion, and students of transport admitted that free-wheeled vehicles, flexible in traffic, able to put passengers down on the pavement and not in the middle of the road, less noisy and more comfortable, more convenient and cheaper, would become formidable rivals to transport on rails. The railway companies were at first contemptuous of the new competition, but year by year not only were more and more passengers travelling by road, but much of the short distance goods traffic began to leave the railway. Between large centres of population not more than a few miles apart, such as the numerous large towns existing in the north of England, and between London and its immense suburbs, the public found it cheaper as well as quicker to go by road rather than by rail to their daily work.

In 1910–1 the dust nuisance became really acute throughout the United Kingdom. The main roads, which had been repaired for years with friable stone or dusty gravel, broke up under the increasing strain of traffic, resulting in muddy surfaces in winter and much dust in summer. Roadside dwellers, who complained with reason, had a real grievance in that they had to keep their windows shut most of the day, while their food was liable to become gritty and their children were smothered in dust while playing by the roadside or in the cottage gardens. The Road Board, first established in 1910 in accordance with the Budget of 1909, devoted its first efforts to making roads dustless, and a year or two later much of the mileage of the main roads near or in towns and villages had been tarred or bituminised. Various local authorities all over Great Britain began to send in applications for grants for making roads dustless and for special purposes. By the Act of Parliament establishing the Road Board the money raised from motor-car taxation was to be allocated solely to improvements, and it was specially stipulated that no ordinary maintenance was to be considered. The Road Board's revenue for the first year was estimated at £750,000. Sixteen years later (1926–7) the revenue from motor vehicles was estimated at £21,600,000, and it is likely that even this huge sum will be exceeded every year for many years to come, though there are already nearly 2,000,000 motor vehicles on the roads, and 2,250,000 driving licences issued.

Improvements in Design.—In the motor-car trade, the years 1911 and 1912 were memorable for the beginning of the "American invasion." As the American cars were cheap in virtue of mass production and the elimination of every needless part, and were fitted with new and attractive devices in the shape of dashboard fittings, screens, self-starters, etc., they rightly scored a success in Great Britain and all over Europe. They taught British makers a much needed lesson, and stimulated the brains of British inventors, designers and constructors. In the earliest days of motoring covered cars did not exist, but a tendency towards closed instead of open bodies soon developed, and became more pronounced year by year. Nowadays (1926) the open car is the exception rather than the rule, and though in the smaller classes there are still many open cars, all are provided with efficient hoods, which have been much improved. Bodywork also has become much more comfortable, and in the more expensive types the luxurious interior of closed cars is a credit to the motor coachbuilder.

The development of cylinders from 1910 onwards is also interesting. Originally (1898–1900) De Dion built his engine with only one cylinder. Then two, and in a few cases three, cylinders came into use. Eventually the four-cylinder engine became the usual type, and by 1919 was practically the only kind to be built. With the Otto cycle (*i.e.*, one power stroke for every four movements of the piston) the four-cylinder engine gives an even torque. But Napier and Rolls-Royce preferred six cylinders, and for the more powerful types this system soon prevailed. Even eight cylinders have sometimes been used, but the six-cylinder engine has been found by experience to be the best type for everyday use. The four-cylinder car is still commonest, however, on account of its cheapness and its light weight.

The gradual development of British automobilism from 1910 up to the beginning of 1914 was much helped by successive shows at Olympia and in many of the provincial towns, which became every year more popular. Racing, too, has played its part in developing speed and reliability. Year after year new speed "records" were set up, and with each year came the destroying of the previous year's recorded speeds. The chief long distance race was for the Gordon Bennett Cup, held on the European continent (except in 1903 when it was run in Ireland), but a road race has never been run in Great Britain owing to the tortuousness of the roads, the congested state of the traffic and the strong public sentiment against speed contests on highways. Brooklands, the first great motor racecourse in the world, was constructed in 1907, entirely through the public spirit and enterprise of Mr. Locke-King. Here regular meetings on the lines of horse-race meetings were organised, provision was made for scientifically accurate timing, and Brooklands began to be one of the most useful institutions in the development of the motor-car.

The motor-car with its internal combustion engine has been the pioneer of many inventions. The aeroplane, of course, is by far the most notable of these, but among land-travelling vehicles the first place belongs to the "caterpillar" type of machine, which includes many varieties adapted to widely different purposes, from the little Citroens which have crossed the sands of the Sahara desert to the gigantic tanks that came into being during the World War. The "caterpillar" system, where the vehicle runs on an articulated endless steel band attached to the vehicle itself, is likely to be of great use in undeveloped countries where there are no roads, and where soft ground, dense grass or reeds or sand make ordinary wheeled traffic impossible.

The motor-car engine continues to improve. The super-charger has been evolved, which increases the pressure of any given engine by supplementing the vacuum created by the descending piston by actual pressure, thereby enabling a greater amount of the explosive mixture to enter the cylinder before the explosion and power stroke takes place. In regard to the number of revolutions, at the Paris show of 1902 an engine was exhibited which attained the then unprecedented rate of nearly 2,000 per min.—an impossibility, according to a high scientific authority, who asserted that no engine could ever run at more than about 1,500 revolutions, as the big ends and crank pins would fly apart owing to the great centrifugal force developed, with the result that the engine would be wrecked! Nevertheless, since then in the Grand Prix races engines have been used and have functioned well which attained 6,000 to 7,000 revolutions per minute! Engines of small cubic capacity have been designed which produce great and unexpected power in proportion to their size. Progress in the science of metallurgy has also contributed to the efficiency of modern engines and gears. Steels of wonderful hardness and strength have been produced to comply with the needs of the modern explosive engine, and further developments are taking place. Before long also we shall no doubt have an infinitely variable gear, superior springing and other improvements. There is food for thought in the fact that, while railways have just celebrated their centenary, the motor-car has had at the most 27 years of active life—about a quarter of that time. When our descendants celebrate the centenary of the motor-car it is probable that the vehicles of to-day which we think so wonderful will have been improved beyond our knowledge or imagination.

Goods Transport.—The development of the motor-lorry has also been considerable, and it may be said without fear of contradiction that the British lorry is recognised as the most efficient and convenient, in addition to having a better appearance than the heavy vehicles produced in any other country. An increased road transport trade has grown up between big centres of industry, especially where manufactures are carried on within a short distance of a seaport, such as in Lancashire, where raw cotton from the ship's side is taken up to the mills by lorry, and finished manufactured goods are taken back as a return load. There has also been a considerable development in the lighter loads, most trading concerns using small lorries and vans for the collection and distribution of their goods. In the country districts the old carrier's horsed cart has been replaced by the carrier's motor-car, running the same journeys in far less time, with greater comfort to the passengers than formerly. There is also in many countries a network of village-to-village and town-to-town services. For agricultural purposes also, not only are motor ploughs being used to a greater extent, but mechanical vehicles are taking the place of the farmer's gig and even his wagon.

Another significant increase has been in the number of motor cycles, of which over 500,000 are running on the roads of Great Britain in 1926. The increase, however, has been somewhat checked by the coming of the small cheap car, which is used by all classes of the community.

United States.—As regards the position in other countries, there are now (1926) in the United States about 20,000,000 motor vehicles, or about one to every six of the population. In many of the large American towns the street cars have become almost deserted, and the workman proceeds to work in his own small cheap car. The growth, too, of roads in the United States has been very remarkable, and new highway construction is proceeding apace, tens of thousands of miles being made every year. The Lincoln Highway now extends right across America from New York to San Francisco, via Pittsburgh, Chicago, Cheyenne and Salt Lake City. The Dixie Highway runs South from Sault Ste. Marie on the Canadian border to Miami, Fla., via Chicago. A number of other important main trunk roads were under construction in 1926 and rapidly approaching completion. In the neighbourhood of New York alone £60,000,000 was being spent in 1926 in abolishing level crossings, making bypass roads and in generally improving the exits from the city.

Europe and the East.—In France, though the number of motorcars has increased since the War, there has not been the same comparative increase as in other countries, the total number being still under 500,000, as against 1,500,000 in Great Britain. In Germany, Austria, Italy, Hungary and the rest of Europe the general increase has been retarded by the comparative poverty of the population over large areas. In India the country roads are being improved for motoring. In China 4,000 m. of main roads have been made to accommodate the increase in motor traffic.

The Future.—The only serious bar to the future increase in motor vehicles in some of the older countries is that all governments are inclined increasingly to consider them as luxury vehicles, and therefore a fit subject for extra taxation. In reality, the day is long past when the ordinary motor vehicle can be considered to be an example of luxury. Ninety-nine per cent of motor vehicles are used for professional, trade, business and other purely utilitarian purposes. There is also the problem which has yet to be solved, namely, how to accommodate in towns the vehicles of those who are employed or occupied for a short or long time during the day. There is no room in the streets, as a rule, to enable this to be done with safety or convenience, and the garage accommodation is wholly inadequate. (*see* MOTOR VEHICLES: ROAD CONSTRUCTION: TANKS: TRAFFIC PROBLEMS.) (M. OF B.)

MOTOR TRANSPORT, MILITARY.—Transport by motor vehicles has profoundly modified the art of war. Their employment enables a commander, despite the unwieldiness of modern armies, to achieve surprise effects which give him victory. In the following account, illustrated by practical examples taken from the use of motor vehicles during the operations of the Allied Armies on the French front, there will be discussed the general principles underlying (1) transport of troops, (2) transport of *matériel* and (3) intensive traffic on roads.

I. TRANSPORT OF TROOPS

The Vehicle.—Troops have sometimes been carried in ordi-ary touring cars. During the battle of the Marne (Sept. 9 1914), t the moment when the French Army of Gen. Maunoury was nassing outside Paris, there were grouped together all available axicabs to take direct to the front the infantry of a division vhich, arriving by rail from the Vosges, was detraining in the tations of the northern suburbs of Paris. This method can only e employed in exceptional cases, because the car or taxicab has o small a carrying power, requiring one driver for every three r four combatants carried, while such vehicles for the most part iffer in speed. On the other hand, such motor vehicles as are esigned to convey a larger number of passengers in peace-time, .g., motor-omnibuses or *chars-à-bancs*, are eminently serviceable.

The ideal vehicle is the common motor-lorry (or truck, as mericans call it). It is necessary to adapt it, *i.e.*, to place in it novable benches, which can be very rapidly installed when it is ecessary to carry men, and can be removed without difficulty vhen it is necessary to carry *matériel*. In accordance with the apacity of the body, which itself partly depends on its load apacity, the lorry can carry from 16 to 25 men with their arms nd equipment.

During the World War not only were units of infantry transorted but also artillery formations; likewise, in some exceptional ases, cavalry with their horses. When horses are to be carried he body of the lorry must be as large and the bottom as low as ossible, to make the loading more easy, and the ceiling must be high enough to prevent the horses from being injured by striking their heads. The horses may be placed either lengthwise or crosswise. But they should be close to one another, to save them from bumping; and there should be no difficulty of access to where their heads are, in order that they may eat and drink on the road. These precautions taken, it has been found that horses travel as well by motor-lorry as in a railway wagon.

Organisation of Lorries.—Lorries move grouped in formations of varying importance, but two essential conditions must be observed: efficient control and effective maintenance. The basic unit, the smallest formation to be placed under the orders of an officer, should be formed of 15 to 30 vehicles. The officer who commands this unit is the veritable sheep-dog of his troop of lorries; he must himself have a touring car (which should be open and not too fast), so as to allow him to follow his lorries when they are on the move, and above all when they are formed into a large column. The officer ought not to lead himself, but be able to keep his attention free, and to jump quickly from his car and speak to his drivers. Next above the basic unit, the "section," is placed the "company" or the "group," normally comprising three or four sections. The commander of the group or company is no longer the sheep-dog of his lorries; he is the shepherd. It is he who guides them in their itineraries, places them in billets and allots them to their work.

The second point in an organisation is to ensure effective maintenance. Automobiles require constant care on a long journey, *e.g.*, 200 kilometres. Some will have breakdowns, some even fall out, too seriously damaged to go on. Minor casualties must be attended to, however, as soon as possible. That is the rôle of the workshops. If the workshop is to move with the group, it must be on lorries, and have a stock of tools and spare parts.

As soon as large transport movements have to be carried out, higher control above the group must be organised. The transport of the infantry of a division requires 12 groups. Placed in a column on the road, this would make a file 36 km. in length, a reasonable distance for each group being 3 kilometres. This mass would be formless and incapable of manoeuvring unless vivified by organisation. It is a common saying that the action of a commander ought to be limited to directing four immediate subordinates and no more. Experience of large demands on transport during the War shows, however, that six groups could be united under one control, if the commander in charge was supported by a fully qualified staff. Such was the composition of the grouping in the French Army; such or something very near it was the composition of the "Bus Park" of the British Army. The grouping of six groups had a capacity for 6,000 infantry; the automobile service of the French Army comprised 25 groupings in 1918.

Organisation of Troop Transports.—Let it be supposed that a grouping is ordered to carry out the transport of 6,000 infantry, to take them up in their billeting area, and to bring them to the field of battle some 100 km. from billets. To accomplish this mission efficiently the staff must first fix the embarkation-points, *i.e.*, the points at which the infantry will be loaded into lorries. In order that this operation may be quickly carried out there must be many loading-points functioning at the same time; to embark one battalion (1,000 men) into a group (80 lorries) requires from 20 to 30 minutes.

When the commander of an automobile grouping has prepared the organisation of his embarkation-points, he must come to an agreement with the infantry headquarters concerned as to the time and place of embarkation of each battalion. The work which devolves upon the command of the lorry grouping in the disembarkation of the troops is generally similar to the above; but there is an additional difficulty, caused by uncertainty as to the exact points of disembarkation, which often depend at the last moment on the military situation. Nevertheless, the procedure must be arranged as early as possible, in close touch with the higher staff which has to fix the disembarkation zone; and an understanding must be arrived at with headquarters as to the probable alternatives, between which a decision will be made later, when the lorries are quite near to the arrival zone. The itinerary between the two zones must be **reconnoitred** and marked out. This is the duty of the officer assisting the commander of the grouping. The " route officer," with his own staff, marks the itinerary by posting up placards (and, for night work, hanging lanterns) bearing the distinguishing mark of the grouping and an arrow indicating the direction of the march and the route to take. Further, the commander of a grouping must organise the movement of his service lorries, supply lorries, work lorries, etc.

Transport of Complete Divisions.—An interesting example occurs when, together with the infantry of a division, it is necessary to transport all or part of their artillery with its horses. With horse-drawn artillery it may be a very serious matter for a general of a division not to be able to bring up to the battlefield, in support of his infantry, the artillery who are accustomed to manoeuvre with him. It is thus very desirable to be able to transport artillery with horses. The loading of guns and limbers on lorries does not present any special difficulty; it is sufficient to have fixed rules for putting the *matériel* in place, and these are the same as the loading-rules for the same *matériel* on railway wagons.

II. TRANSPORT OF MATÉRIEL

Lorries are not specialised for the transport of *matériel*. The same type is employed as for troops, and therefore, the organisation is similar. A lorry-group capable of moving a battalion of infantry can alternatively move 100 tons of *matériel*. Experience in the World War has shown that, during the periods of active operations, a division requires an average of 200 tons per day in foodstuffs and ammunition. This is equally true in the case of defensive areas, as at Verdun; in offensive actions of the type of the Somme battles in 1916; or those of July, Aug. and Sept. 1918, on the Marne. Two groups are therefore required for the supply of a division, subject to the distance from the railway being, at furthest, within a radius of 40 kilometres. Four groups are necessary if the division is 70 km. from a railway. An average of 3 hours must be reckoned for loading at the stations; with allowance for difficulties arising amid intensive operations, 7 or 8 hours are taken up on the journey and 2 hours in unloading. This gives about 13 hours for work, and leaves 11 hours per day for the maintenance of *matériel*, feeding and rest. If the traffic operations are to be continued for a number of days, any more than this cannot be demanded of the personnel or of the *matériel* without risking excessive wastage. On the day after a journey with loads the vehicles return empty, and on the day after that they recommence the journey loaded. As 200 tons a day are required for a division there must be a double set of two groups, with a total capacity of 400 tons.

Non-Specialisation of Matériel.—At a general mobilisation like that at the opening of the World War, the resources available for transport are necessarily limited not only by financial conditions, but by the number of vehicles in existence in the country capable of being requisitioned, and by the maximum production of the manufacturing firms. On the other hand, there is no limit to the requirements in lorries, because no general worthy of the name thinks he has a large enough stock of transport at those critical times when every addition means an increase in his power of manoeuvre. During the 20 days which intervened between May 27 and June 15 1918, the lorries of the French Army had to transport about 800,000 tons of foodstuffs and munitions, in order to ensure the supplies of those armies which were making headway against the German attack. And yet, during this same period, the French Headquarters Staff had transported by automobile the infantry of 63 divisions. It was necessary also to make numerous evacuations of public records, civil populations, hospitals and engineer parks. This wonderful effort was only possible because in the French Army the principle of non-specialisation was adopted. Every lorry was controlled by the motor transport service of the armies, and was utilised by it for any form of transport needed. No vehicle was specially or permanently attached to this or that higher or lower formation. When a higher formation, such as a division, had need of transport, the automobile service arranged the transport, but as soon as it was finished the lorries employed on this service returned and were available for other transport service In short, the lorry capital never remained unproductive.

The Use and Duties of Depôts.—The reasons for avoiding t wastage of lorries apply likewise to avoid wastage of movement The carrying-out of " detail " transport is the principal cause low efficiency. In the battle of Verdun, March 1916, the supp of munitions was taken by rail to Bar-le-Duc and to Baudo villiers. Trains of munitions arrived daily at these two statio to supply the artillery of the 10 divisions deployed arou Verdun, some 60 km. from the stations. If, to supply each these divisions, there had been allotted a motor formatio which could come to load up at the stations and go as f as the batteries, bringing munitions, the efficiency would ha been mediocre and uncertain. An accident at a depôt, an inte rupted road, an advance or a check at the front, would set ba the whole time-table of the formation, and one would have se them arriving in the station for loading their lorries in twos a threes in disorder, and at different hours. There can never efficiency unless there is regularity of movements. It is nev possible to have regularity unless the traffic of the back area which can be regular, is definitely separated from the traffic the front areas, which is always uncertain. This separation ca be effected by the creation of depôts depending on the lines-o communication authorities, and supplied by them where th formations from the front areas come to refill exactly as the would refill from the railway if there were stations at these front

III. INTENSIVE TRAFFIC ON THE ROADS

The Route Gardée.—For the organised employment of automobiles on the roads, like that of railway trains, the essentia condition is to be master of the road. If all and sundry are pe mitted to put columns of troops or vehicles on a road, it is useles to attempt to carry out important movements. It is an absolut rule, based on experience, that it is not possible to launch a bi transport movement involving several hundreds of lorries without being absolutely certain of the complete freedom of the road during the whole time that the movement will last. Hence th organisation of the *routes gardées*, with their personnel of guard and their traffic orders.

A *route gardée* is not necessarily reserved exclusively fo automobiles. But in every case there must be a responsibl authority, having power to give orders and have them carrie out. In the French Army, during the War, this authority was motor regulating staff (C.R.A.). In the British Army, the contro of traffic in France was part of the duties of the provost marsha (A.P.M.). The organisation of the route, on a railway model, i based on the block system. The route is divided into a series o districts, each of which is under the direction of a district chief having assistants for supervision. The district chief is in constant touch by telephone with the neighbouring districts, an with the office of the C.R.A.; he knows all the movements which affect his district, and also keeps a record of all movements which occur there and all the incidents of the traffic. Thus at the offic of the C.R.A. it is always known what the state of the traffi may be on every *route gardée*, and the necessary arrangements for launching an important movement can be made in give time. The route orders for the *routes gardées* are more or less drastic according to the breadth of the road, and whether or not there are relief routes.

The length and the importance of the districts on a *rout gardée* depend, obviously, on special difficulties to be overcome, *e.g.*, the number of adjacent routes, the localities traversed, narrow passages, etc. Between Bar-le-Duc and Verdun there were six "districts" varying in length from 5 to 10 kilometres. It is quite unnecessary to control in this permanent fashion a route over which there is not continuous traffic. Whenever such a road is needed, for the time being, for an intensive transport, it is sufficient to occupy it immediately and transform it into a *rout gardée*. This requirement leads to the C.R.A. (or any corresponding organisation) being given a territorial zone of operation. In each zone it is the immediate business of the C.R.A. concerned to guard any portion of the road over which the transport will be moving. For this purpose the C.R.A. had at its disposal specially organised personnel, which may be fairly accurately designated "mobile districts," and which, being in the habit of operating in this way and supplied with the means of rapid installation, can, in two or three hours, make themselves masters of the traffic on whatever part of the road is entrusted to them.

Maximum Efficiency over a Road System.—When one is master of "circulation" throughout a given region, one is free to aim at maximum efficiency. Formerly, when the staff proposed to carry masses of troops to a theatre of operations it traced the greatest number of parallel and serviceable roads which led to the zone of action decided on, and there was thrown on each of these roads a column of all arms scientifically echeloned in depth. Thus it was that Napoleon moved from the Rhine to the Main in 1805; thus, also, Moltke moved from the Sarre to the Moselle in 1870. When this system is applied to present-day conditions the efficiency of the road system is low, because the increase of speed due to the automobile is not turned to account. All modern armies have tractor-drawn heavy and automobile light artillery, and possess the means of transporting the bulk of their infantry by motor lorry. There remain the horse columns, on which it is no longer necessary to impose the speed limitations of marching infantry. In consequence, in co-ordination with the movements made by railway, the movements by road ought to be organised in the form of special itineraries, on each of which move columns of elements that are homogeneous from the point of view of speed. Thus combination of movements can be worked out in which much time is saved, as compared with the old methods.

The existence of regulating commissions in charge of zones of movement and masters of the traffic, considerably eased the French problem. But the regulating commissions must have control not only of automobile traffic, but of all traffic; in their zones no movements must occur without their having received notice and taken the necessary measures to facilitate the execution of the movements in question. They must be able to arrest all false movements in good time. And they must be in close touch, so as to form a complete network, covering the whole area over which it may be necessary to move any column. It was by the functioning of an organisation of this nature that the French Army was able to make its concentrations of considerable numbers of troops at very short notice in March, May and July 1918.

Strategic Transport by Road.—As the automobile has brought on the road again the tourist who had deserted it since the middle of the 19th century, so transport by motor lorry has brought into use again strategic movements by road. And, for the production of surprise effect, by adding the roads to the railways, it has been possible to put to full use all available means of communication. The air alone has not been utilised; but in the future it may be utilised for the quick transport of combatants. In order that movements by roads should be serviceable, it is necessary for them to be rapid and powerful; this is attained by applying the same principles as in rail movements—that is to say, the temporary break-up of large units for transport.

Combined Use of Railway and Motors.—In the majority of cases use is made of railways and roads in combination. The end to be attained is always a rapid move of powerful forces; the staff should therefore make use simultaneously, and as efficiently as possible, of every means of transport which it possesses. One must never lose sight of the fact that the efficiency of the railway s much superior to that of the road; a train of 50 wagons is equivalent to 150 lorries. At a speed of 30 kilometres an hour, and with four departures an hour, one has four trains in a length of 30 kilometres, or the equivalent of 600 lorries. We have seen hat 600 lorries form on the road a length of 20 to 25 kilometres. Railway and road have therefore very nearly the same output. But the lorries, going 15 kilometres an hour, are only half as quick. Further, at the end of 100 kilometres it is necessary for he lorries to stop in order to rest the drivers, for, save in exceptional cases, relief crews are out of the question. The weak point n transport by rail really lies in the necessity of having stations or embarking and for disembarking. Save in quite exceptional ases it is an absolute technical necessity to load and unload in stations, and, even so, only in those where there are sidings sufficient to take the military trains so as to leave free the main line during the times of embarking and disembarking. Without this precaution all the traffic will be blocked. Further, when it is a question of loading *matériel* it is necessary to place it on the platforms. While special platforms or docks are indispensable on the railway, it is always easy, on the road, to find or organise quickly loading-places for lorries.

Big movements by railway can be made only from a zone A to a zone B, if the two zones A and B are equally rich in loading-places. But—apart from those points which come into the initial concentration scheme, and on which, therefore, work can be done in peace—it is impossible to ensure, in the large movements which military operations may necessitate at any given moment, that the beginning and the end of rail transports shall take place in zones that are rich in loading-places. On the other hand, it is generally possible to find, within a radius of 50 to 100 kilometres in the zones A and B under consideration, one or more regions rich in loading-places. The normal combination consists therefore in utilising motor transport to prolong railway transport, and to carry the troops or *matériel* (1) from their stationary zone to the places of embarkation, and (2) from their places of disembarkation to the zone of operations. The relatively short movements (50 to 100 kilometres) it requires are those in which the efficiency of the lorry is at its greatest. And between the two zones of loading thus actually used, the efficiency of the railway will equally be a maximum.

Naturally, other combinations are also practicable; for example, that by which, on Nov. 20–21 1917, three French divisions were to be carried from Meaux and Château-Thierry to Péronne; the infantry, with their machine-guns and cooking-carts, being conveyed in motor lorries, and the artillery by train. The object of these movements, very quickly ordered on Nov. 19, was to reinforce the successful British attack in front of Cambrai with the first use of tanks in mass, and had overwhelming results. While the embarkation of the artillery was proceeding at railway stations in proximity to the divisional billets on the Marne, the C.R.A. of Meaux and Château-Thierry loaded up on 3,000 lorries the infantry, etc., of the three divisions.

There are many details which complicate considerably the task of the transport officials; such as the question of food supply for the troops during their transportation and at their disembarkation, and the question of moving troops simultaneously with the building-up of the munition dumps which they will require. One last remark should be made: transportation by automobile and by railway, which, we have seen, supplement one another happily in regard to distance, is equally satisfactory in regard to time. Large movements by railway require concentration of *matériel*, often difficult to achieve; and, in the case of moves decided on in a hurry, the possibility of motor transport on a large scale assumes very great importance, since it takes four or five days for the railway to show its full powers.

Conclusion.—The experience of the War shows the rôle which transport by motors is called upon to sustain becoming more and more important. The Allied Armies, together, placed on the French front about 20,000 motor vehicles in Oct. 1914; four years later the number exceeded 200,000. At the time of the Armistice, the inter-Allied transports reserve, the creation of which had just been decided on, was of a size to transport simultaneously 10 divisions of infantry complete, with all their means of fighting, machine-guns and artillery included. This was a fighting mass of more than 100,000 men, which the Higher Command was able to pick up at short notice and carry at the speed of 100 kilometres a day to any point where it was required.

As regards the transport of *matériel* at the end of the War, it had become possible—independently of the resources just mentioned—to keep supplied with food and munitions 40 divisions at a distance of 100 kilometres from the railways.

MOTOR VEHICLES (*see* 18.914).—The greatest industrial development of the first quarter of the 20th century was that of the motor road vehicle. Development of the self-propelled, petrol-engined vehicle began in Germany in the eighties with the work of Daimler and Benz, and was carried forward particularly energetically in France for more than a decade, from 1895 on.

I. HISTORY OF MOTOR VEHICLES

About 1910 the United States assumed the leadership in the production of this type of vehicle. Transport and other conditions naturally favoured the use of motor vehicles there. American manufacturers cut down their production costs materially below those in Europe, in spite of the higher wages paid by them, and thus sold their cars at very reasonable prices. By 1925 more than one half of all the families in the country had their own car and more than 83% of all the cars in the world were owned in the United States. Registration figures showed that on Jan. 1 1926, there was one vehicle to every 5·7 persons in the whole country, while in California, the state with the greatest "motor density," there was one to every 2·8 persons. Motor-vehicle manufacture had become the greatest manufacturing industry in the country, in point of value of output.

Economic Reasons.—While the World War accelerated production of motor-cars in the United States and retarded it in those European countries which were engaged in the conflict from the start, the chief reasons for the pre-eminence of the United States as a motor-using country are of an economic nature. America is a land of magnificent distances; in many sections towns and cities are far apart, and long trips must often be made over the public roads, for which purpose horse vehicles are quite unsatisfactory. Petrol (in the United States called gasolene), the fuel commonly used for motor vehicles, is a native product, comparatively cheap and plentiful. The *per capita* wealth is greater than in most countries and well distributed.

Not all conditions were favourable to the introduction of motor-cars, however. The industrial countries of Europe had magnificent systems of hard-surfaced roads, which were practically non-existent in the United States at the beginning of the motor era. This, though a handicap, did not prove a serious obstacle. In the early years of motor-car development the private passenger car was generally regarded as a means of pleasure, and in Europe this remained its chief function. But in the United States and Canada (where the proportion of motor-cars to population was not much less than in the United States) it became a great factor in business life. In New York City, for instance, a very large proportion of the street traffic in 1925 was by motor, and in the main thoroughfares horse vehicles were almost a rarity. Such agricultural states as Iowa and Nebraska had relatively more cars than the industrial states, and the farmers used their cars chiefly for business purposes. As the substitution of the motor-car for the horse came about gradually, it did not greatly impress the general public; nevertheless, it profoundly influenced modern life.

Bus and Jitney Services.—In the cities of the United States the once familiar horse cabs and hansoms had disappeared before the motor-propelled taxicab by 1925. Numerous bus services competed with the tram services, particularly in outlying districts, and even cut heavily into the local passenger business of the railways. About 1915, many owners of private cars began carrying passengers in competition with tram lines, their vehicles being known as jitney buses (jitney, a Russian coin about equal in value to five cents, then the common tram fare). These jitneys did much business, especially during the "rush" hours when people go to work and return home, as their passengers avoided the crowding of the street-cars and the annoyance of frequent stops. In some sections of the country conditions were made rather hard for the jitney owner by legislation, and the business shrank or ceased entirely; while in others, and particularly in Detroit, it was still thriving in 1926.

Freight Haulage.—Motor-trucking and the haulage of freight by motor vehicle began to assume importance in the United States only about 1910. This branch of the industry up to then had been more successful in Great Britain and Germany. From 1910, however, it consistently increased in the United States, where under war conditions the motor-lorry even entered into competition with the railways. An enormous amount of motor freight traffic grew up over certain routes between important industrial cities, as between Detroit, Mich., and Toledo, O., and between Akron and Cleveland, Ohio. One large tire manufacturing company in Akron, O., with cotton mills in Boston, Mass., over 600 m. away, established a fast freight service, between these two cities, of motor-trucks on pneumatic tires. Some of this development was evidently due to the abnormal conditions which made railway freight service inadequate during and immediately after the World War. Military operations gave a great impetus to motor-truck development. In addition to the urgent demand for trucks for military purposes there was also a strong demand for business purposes, owing to the intense industrial activity and to the breakdown of the railways under the war strain.

Advantages.—The substitution of the motor-car for the horse was beneficial in various ways. In the first place the car is much more speedy and more comfortable for transport. With a motor-car a physician, for instance, can extend his practice over a much wider territory; contractors can oversee more thoroughly a number of projects under way at the same time; stores and factories can deliver goods in the country, at distances of 30 m. or more, in their own vehicles, while horse delivery was limited to the city. Stables, always a nuisance and a breeding place of disease, have been practically eliminated from cities, and street-cleaning has been rendered much easier. Real estate remote from railways has in many instances considerably appreciated in value as a result of the advent of the motor-car, rendering it accessible to the city man.

In the foregoing the utilitarian aspect of the motor-car has been specially emphasised. While cars are still being built that can properly be classed as vehicles of sport and luxury, they form a small proportion of the whole production. In New York City an annual show was established for this class of car; it started as the Importers' Salon, but during the World War, when the importation of European cars was very difficult, it gradually changed its character and became a show of high-grade domestic as well as imported cars. At the salon in Nov. 1920, there were exhibited cars selling at upward of $20,000, whereas a serviceable five-passenger car could be bought for as low a price as $550. The luxury cars exhibited at these shows were characterised by high power and high speed, elegant body finish, fine upholstery and superior equipment.

European Conditions.—In 1910, Great Britain had the leadership among European countries as regards the number of cars in use, whereas France led in respect to volume of production. About one-half of the number of cars produced in France at that time were exported. In continental Europe the introduction of motor-cars was hampered by heavy taxation on the cars themselves and on the fuel. The use of motor-trucks, on the other hand, was encouraged by the so-called subsidy system, by which purchasers of trucks suitable for military purposes were offered by their governments a bonus on the purchase price and also on the upkeep cost, in consideration of their keeping the trucks always in fit condition and agreeing to turn them over to the Govt. in case of war. Great Britain, France and Germany had such subsidy systems before the war; Japan adopted the same policy later. As soon as war was declared the motor-car factories were set to work for the war departments, either making trucks or other vehicles for the transport corps or else manufacturing aero-engines or munitions. Soon all the petrol available was needed in war service, and the use of motor vehicles by private parties practically ceased.

In England some use was made during the War period of town gas for motor fuel; this was carried in a collapsible bag of rubberised fabric, on the roof of single-deck omnibuses, for instance. With this fuel it was possible to obtain about 85% as much power from an engine as with petrol, and a satisfactory mileage on one filling was secured. Under normal conditions the gas would have

been carried in steel bottles under high pressure, but owing to military requirements no steel could be spared for this purpose. The Central Powers suffered much more from fuel shortage than did the Allies, and extensive researches on substitute motor fuels were carried out in Germany. After their petrol supply ran low the Germans used benzol, petroleum mixtures, benzol-alcohol mixtures, alcohol, wood alcohol, tar oil, gas oil and shale oil, as well as fuels produced synthetically from water gas by catalytic hydrogenation under high pressure and at high temperature.

Registration in Great Britain.—According to an announcement by the Minister of Transport, Great Britain, on March 31 1920, had 185,700 private passenger vehicles and 71,400 public-service vehicles. The numbers of lorries and motor-cycles in service on that date are not available, but during the period Jan. 1—March 31 1921, licences were issued for 15,000 motor lorries and 278,500 motor cycles. How rapidly the use of the motor vehicle increased during the next four years may be judged from the following figures issued by the same authority as on May 31 1925: licences issued for private passenger cars, 532,909; for motor cycles, 518,457; for commercial goods vehicles, 216,966; for hackneys, 92,024; trade vehicles, 13,018, and official vehicles, 14,912.

Registration in the United States.—The figures given in Table I. are based on information furnished to *Automotive Industries* by the registration officials of the different states. Allowances were made for re-registration of cars sold by their owners during the registration year and for registration of cars by non-residents, and the table is believed to give as accurately as possible the number of cars in service in each state during the years mentioned, by residents of the respective states.

TABLE II. *Registration of Passenger Cars, Lorries and Motor cycles in Different Countries at the End of 1924*

(In round number)

	Passenger Cars	Lorries	Motor-Cycles	Total
United States	15,597,000	2,142,000	139,000	17,878,000
Great Britain	625,000	217,000	518,000	1,360,000
France	460,000	115,000	102,000	677,000
Canada	576,000	63,000	8,000	647,000
Germany	132,000	61,000	98,000	291,000
Australia	180,000	18,000	55,000	253,000
Italy	72,000	28,000	38,000	138,000
Argentina	120,000	5,000	3,000	128,000
Spain	56,000	10,000	7,000	73,000
Holland	24,000[1]		36,000	60,000
Norway	13,000	5,000	7,000	25,000

[1] Includes both passenger cars and lorries.

II. TECHNICAL DEVELOPMENTS

A most desirable feature in a motor car is flexibility, that is, the ability to pass from a low to a high speed by merely opening the throttle valve. This is secured by using an engine of great power in proportion to the combined weight of the car and load. American cars have been specially noted for their flexibility, due to the use of very large engines, notwithstanding the fact that the high fuel consumption per mile travelled tends to increase with the displacement of the engine. As motor fuel was much more expensive in Europe, European designers could not ignore the factor of fuel economy as American engineers could.

Engine Design.—In engine design the constant endeavour is to get greater output from an engine of given piston displacement. Horsepower output depends upon two factors, the mean effective pressure upon the piston head and the linear speed of the piston. It was not possible to increase greatly the mean effective pressure; in fact, changes in the character of the fuel used for motor cars, by which some very much less volatile fractions were included than in motor fuel of the earlier period, made it necessary to operate with lower compression, which resulted in a lower mean effective pressure. However, improvements in combustion chamber design and other changes more than balanced this loss. A great gain was made by increasing the speed of operation. In 1905 the average engine speed corresponding to maximum engine output was about 1,000 ft. per min.; in 1926 it was approximately 2,500 ft. per min. for passenger-car engines and over 4,000 ft. per min. for racing engines. The first step to increase engine speed was enlargement of valve ports and passages, enabling the engine to draw in a normal amount of charge at a higher speed. The valve timing was also changed, the exhaust valve being given a greater lead and the inlet valve a greater lag.

Next, the reciprocating parts (piston and connecting-rod) were lightened, so as to reduce the inertia forces on them and the bearing pressures resulting therefrom. This led eventually to the adoption of aluminium alloy pistons. Aluminium has a higher co-efficient of heat expansion than cast iron, so that the aluminium piston must be given a greater clearance in the cylinder, which tends to result in unpleasant piston slap when the engine is cold, and also in "oil pumping," that is, transfer of lubricating oil from the crank chamber to the combustion chamber, with consequent smokiness of the exhaust. These difficulties were overcome in later designs by the use of the split-skirt or constant clearance type of piston, in which the skirt or lower part is separated from the upper part or ring belt all around and is saw-slotted longitudinally so that when the aluminium expands the saw-slot will become narrower and the clearance between piston and cylinder wall remain substantially the same. In a few instances magnesium alloy pistons and heat-treated duralumin connecting rods were used, magnesium having a specific gravity about two-thirds that of aluminium, and duralumin, an aluminium alloy responsive to heat treatment, having the strength of mild steel with only one-third its specific gravity. Special means were resorted to in attempts to build ultra high-speed engines, as for racing and similar purposes. These included the use of two inlet and two exhaust valves per cylinder, the use of two simultaneous ignition sparks in each cylinder, and the use of crankshafts in which each individual throw was counterbalanced.

Cylinder Development.—By increasing the number of cylinders above the one or two employed in the first machines, engines can be reduced in weight, and the objectionable vibration can be minimised. In 1926 the four-cylinder engine was the foremost type for use on vehicles of a strictly utilitarian character; the six-cylinder was the luxury type in Europe, while in the United States it was the preferred type for passenger cars of intermediate and higher grades. Most of the more expensive passenger cars in the United States then were fitted with eight-cylinder engines. The twelve-cylinder or twin-six engine enjoyed a spell of popularity during and immediately after the War but disappeared from the market as a motor-car power plant in 1923. In a petrol engine the torque impressed upon the crankshaft is always non-uniform, no matter how many cylinders there are, but the fluctuations decrease with an increase in the number of cylinders. In a four-cylinder engine there is, as with one or two cylinders, a reversal of the torque; that is, just before the end of each stroke the flywheel not only supplies all the power delivered by the engine, but also some of the power necessary for keeping the crankshaft and pistons in motion. Six cylinders are the smallest number delivering continuous torque at the crankshaft; but while continuous, the torque is still far from being uniform; with eight cylinders the torque fluctuations are reduced, and with twelve they are still smaller.

Arrangement of Cylinders.—Four and six-cylinder engines were always arranged vertically, with all cylinders in a row; eight-cylinder engines were originally built in V form, but in 1926 the majority of the makes had all eight cylinders in line. In an eight-cylinder V engine with the two cylinder blocks at an angle of 90°, and with a single plane crankshaft there is an unbalanced periodic inertia force in the horizontal plane, the period of which is equal to the time of one-half a crankshaft revolution. By placing the two cylinder blocks at an angle of 60° a uniformly rotating unbalanced inertia force of constant value is obtained, of a magnitude considerably less than the maximum value of the unbalanced force in the 90° V, and this led two makers, Lincoln and Wills, to use this arrangement of the cylinders, which, incidentally, suffers from the disadvantage that the explosions are not evenly spaced but come at 60° and 120° intervals. A method of completely balancing an eight-cylinder 90° V engine was discovered by Prof. Archibald Sharp and described in his book on *The Balancing of Engines*, issued in 1907. It was first practically adopted by the Cadillac Motor Co. in 1923. Instead of having all four throws of the crankshaft in a single plane, the throws are arranged in two planes making an angle of 90° with each other, and the crankshaft is provided with two heavy balance weights, as shown in fig. 1, which represents the Cadillac crankshaft. In deciding upon the form of the crankshaft of a multi-cylinder engine and the angle between cylinders in a V engine two objects are aimed at, namely, to ensure uniform spacing of explosions and inherent balance of reciprocating parts. Both objects can be attained in six and eight-cylinder engines; in a four-cylinder vertical engine there is an unbalanced reciprocating force in a vertical plane, causing vibration of the engine. This can be overcome only by the use of an anti-vibrator, invented by F. W. Lanchester, consisting of an unbalanced mass directly below the crankshaft and driven from the latter at twice its speed.

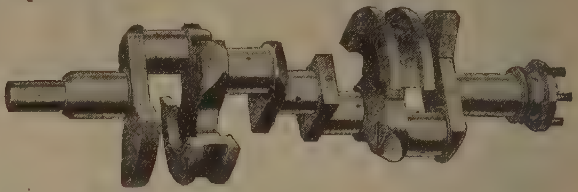

FIG. 1.—Balanced crankshaft for 90° V-type eight-cylinder engine (Cadillac).

When multi-cylinder engines were first used the cylinders were generally either cast separately or in pairs; later it became the practice to cast all cylinders in one row in one block. This greatly simplified the outward form of the engine, as with such a cylinder block only one pipe connection each need be made for the cooling-water inlet, the cooling-water outlet, the combustible charge from the carburetter and the exhaust. Some manufacturers even cast the top part of the crankcase integral with the cylinder block and made the lower part a steel pressing. This construction lent itself well to quantity production. Most makers of the higher-priced cars, produced in smaller numbers, cast all parts of the crankcase of aluminium. Cylinder heads were generally cast separate from the cylinder block and fitted to the block with a gasket of sheet copper and asbestos between. This construction facilitated manufacturing operations, and when the engine was in service permitted decarbonising the combustion chamber by scraping without removing the cylinder. It also made it possible to machine completely the combustion chambers, and thus to get all the chambers in one engine of exactly equal volume.

Combustion Problems.—As the speed of automobile engines increased it became necessary that the combustion of the fuel mixture charge be completed in a shorter period of time, in order that the maximum fraction of the heat energy might be converted into mechanical work. Racing engines in 1925 operated at speeds above 5,000 r.p.m., at which the time of one complete piston stroke is less than $\frac{1}{160}$ sec., and combustion should be completed before the end of the stroke. Prof. Bertram Hopkinson observed in 1912 that the rate of flame propagation through a combustible mixture can be increased by producing turbulence in the mixture (in the experiment, by means of a revolving fan in a closed vessel containing the mixture). In order to obtain a similar effect in the combustion chamber of an engine, Harry Ricardo has suggested the use of a "turbulence cylinder head," as illustrated in fig. 2. The compression space is in the form of a pocket in the cylinder head, mainly over the valves, which are located in a side pocket, but partly over the cylinder itself. At the end of the compression stroke the piston approaches very close to the flat portion of the cylinder head, and this produces a lateral rush of the combustible gases into the compression pocket, causing turbulence. Compression heads of this general form were widely used in 1926.

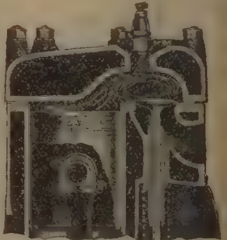

FIG. 2.—Turbulence type cylinder head.

The compression space should be as compact as possible, so that for a given volume its surface area and the distance from the spark points to the remotest portion of the charge are both a minimum, as this tends to promote rapid combustion, to prevent detonation (excessive explosion pressure and resulting phenomena) and to reduce the loss of heat energy to the cylinder jacket. Recognition of these relationships led to the gradual abandonment of the T head type of cylinder (with inlet and exhaust valves in pockets at opposite sides) and to the wider adoption of the valve-in-head engine, which latter in 1926 was used on racing cars to the exclusion of all other types. Valves in the cylinder head can be operated either from a camshaft in the crankcase through tappet rods extending up the side of the cylinder and tappet levers on top, or from an overhead camshaft. The overhead camshaft design reduces the weight of the valve reciprocating parts, and with given valve spring pressure makes possible the use of higher engine speeds. Racing and air-craft engines (*see* AERO-ENGINES) were generally fitted with overhead camshafts. On the other hand, in passenger car engines valves in the cylinder head were generally operated through long tappet rods, as it was found difficult to obtain the desired degree of silence with overhead camshafts.

Marmon, in the United States, used a cast aluminium cylinder block for a passenger car engine for a number of years prior to 1920, but gave it up because it proved impossible to keep the cylinder bores true. Cast-iron sleeves were inserted in the blocks to form bearing surfaces for the pistons, and the valves were located in cast-iron cylinder heads. The trouble was evidently due to distortion of the aluminium castings under the high temperature of operation. It was later found that distortion of aluminium engine castings in service can be prevented by subjecting them to a heat treatment after machining, at a temperature slightly higher than the maximum they reach in service. Some years after the War, German engineers became interested in aluminium engines, and at the Berlin automobile show of 1923 there were exhibited six makes of car with such engines.

Fuels.—The continual lowering of the volatility of the fuel used caused both manufacturers and users of motor cars a great deal of trouble, particularly between 1915 and 1920. When motor cars were first used, the fuel sold consisted of a comparatively narrow range of highly volatile hydro-carbons. When sprayed into air at atmospheric temperature in the required proportion of about one part by weight of petrol to 15 parts of air it vaporised readily. The fuel supplied in the United States in 1920 had an end point of nearly 475° F., that is, the least volatile constituents, when under atmospheric pressure, boiled only at that temperature. Hence, in order to vaporise this fuel completely it was necessary to supply heat to the mixture or to the components before they were mixed. When trouble from incomplete vaporisation was first experienced the carburetters were provided with a jacket through which hot water from the engine jacket was circulated. When this no longer sufficed, the air for the carburetter was drawn through a muff surrounding a part of the exhaust manifold, and to prevent recondensation after the mixture was formed, the inlet manifold was so arranged that it was completely surrounded by hot water.

This also proved inadequate, and then the hot spot or exhaust-heated manifold was introduced. When the fuel is incompletely vaporised the liquid particles tend to separate out of the mixture at the bends in the manifold, and it is very difficult to insure that all cylinders get mixture of the same composition. Those portions of the manifold wall where the liquid particles tend to accumulate are then made to form parts of the exhaust manifold wall also, so that they are constantly kept at a high temperature, and the liquid particles upon striking them flash into vapour. The change in the character of motor fuel between 1916 and 1919 is strikingly illustrated by the diagram (fig. 3) of distillation curves of the fuels purchased in Detroit, Mich., at various times during that period. Later the fuel improved again slightly and a survey made by the U.S. Bureau of Mines on Jan. 1 1925, showed an average end point for petrols sold in different parts of the country of 425° Fahrenheit.

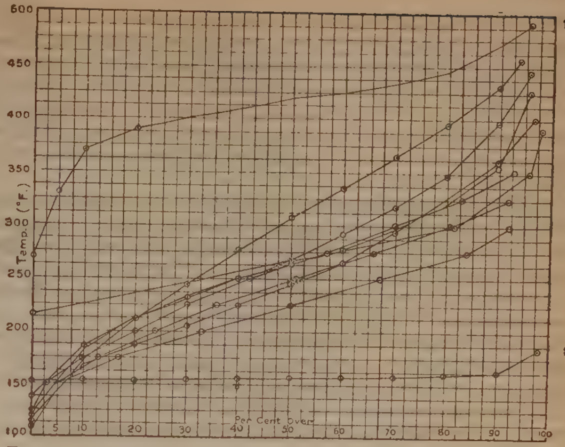

FIG. 3.—Distillation curves of motor fuel sold in Detroit, Mich., from 1916 to 1919. The data for each curve are as follows:—

Curve No.	Fuel	Date of Purchase	Baumé
1	Petrol	4/5/16	60·5
2	Petrol	7/10/16	57·5
3	Petrol	9/11/16	56·8
4	Petrol	6/9/17	56·8
5	Petrol	1/24/19	57·3
6	Petrol	4/30/19	55·7
7	Petrol	6/18/19	55·0
8	Alcohol	10/18	42·2
9	Cal. Dist,	18	51·4
10	Paraffin	18	40·0

Carburetters.—Numerous improvements in carburetter design were made between 1910 and 1926. Decreased volatility of the fuel necessitated the provision of special means to facilitate engine starting, particularly in cold weather. American engineers, who were confronted with the problem first, generally made use of a choke valve in the air inlet, which is closed when it is desired to start. This greatly increases the suction on the fuel nozzle and results in a great excess of fuel being drawn in. As only the most volatile part of this fuel will be vaporised, this excess of fuel assures the formation of an ignitable mixture. Another scheme, which originated in Europe, consists in the provision of a special starting nozzle delivering fuel into the carburetter passage above the throttle valve.

For starting, the throttle is closed and the effect on the starting nozzle is then the same as that on the main nozzle when the choke valve is closed. Most of the earlier carburetters had the fault of delivering an impoverished mixture in case the throttle valve was opened suddenly, causing the engine to halt and even to stop. With later carburetters the fuel-metering orifice is placed at the bottom of the carburetter instead of at the top of the spray nozzle. Between it and the top of the nozzle an accelerating well is provided which filled with fuel when the engine was stopped or throttled down to a low speed. Then, if the throttle were opened suddenly, the contents of the well were discharged into the induction system almost instantly, and the richness of the mixture was maintained.

Another improvement that came into wide use on carburetters between 1920 and 1926 was the economiser. Research work on carburetters and engines showed that for best all-round results the strength of the mixture must be varied with the demand on the carburetter. Maximum power is obtained from the engine with a petrol-air mixture of about 1:12·5, whereas the maximum fuel economy is obtained with a mixture of about 1:16. At extremely low speeds the mixture should be comparatively rich, because the fuel then is not sprayed very energetically and not all of it is vaporised, and only the vaporised fuel counts in the mixture. Throughout the greater part of the range in demand the carburetter should furnish the maximum-economy mixture, for obvious reasons. However, if the throttle is opened wide, the driver wants either the maximum torque (as in ascending very steep hills), or else the maximum power (as in a burst of speed), and in that case the carburetter should deliver the maximum-power mixture. This is accomplished by making the stem of the throttle valve, when approaching the position of maximum opening, change the setting of the fuel metering devices in such a way as to enrich the mixture.

Air Cleaners.—About 1920, American manufacturers began to use air cleaners on passenger car engines, to prevent road dust from getting into the cylinders and causing abnormal wear. The cleaners used were of either the centrifugal or the strainer type. With the former the air is set in rotation in a cylindrical chamber by being drawn in by the engine suction through tangential or helical passages. Centrifugal force caused the heavy dust particles to collect on the cylinder wall and to drop out into a collector, often a glass jar, while the air, deprived of its dust content, is drawn off at the centre of the cylinder. With the strainer type the air is drawn through a large area of filtering felt.

One difficulty encountered in the use of exhaust heat for vaporising the fuel is that the heat supplied does not vary in accordance with the needs when the load on the engine is varied. When the engine is heavily throttled and runs under light load at low speed, the suction on the spray nozzle is small, and consequently the fuel is not finely sprayed. Relatively more heat is needed to ensure the vaporisation of the larger globules of fuel, but under these conditions of operation the exhaust does not supply a great amount of heat. A device designed to overcome this difficulty was developed by the Packard Motor Car Co., and is known as the fueliser. With this (see fig. 4) a variable fraction of the mixture prepared in the carburetter mixing-chamber is shunted around the throttle valve and through a heating jacket of the carburetter, where it is kept burning by a constant stream of sparks delivered by a sparking plug. The products of combustion are combined with the main stream of combustible charge and pass on into the cylinder. When the throttle valve is fully open there is very little resistance to the passage of the combustible mixture past it, and very little then flows through the by-pass or heating jacket; on the other hand when the throttle is nearly closed the passage through it offers much more resistance, and a much greater proportion of the fuel charge passes through the heating jacket, which is in accordance with the requirements.

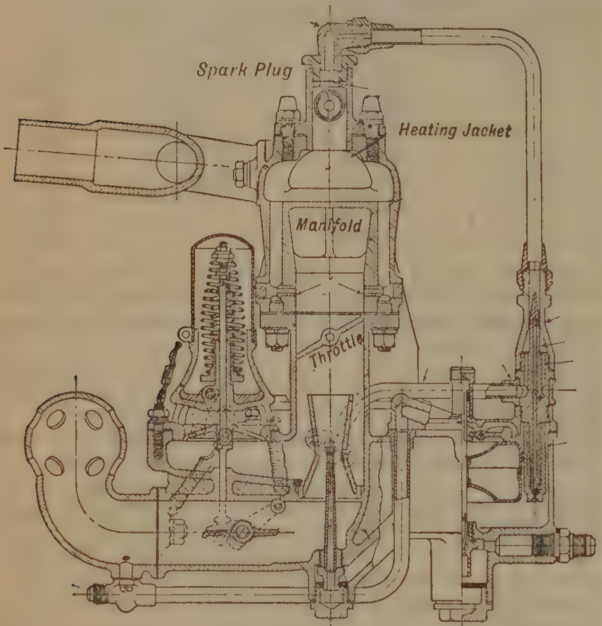

FIG. 4.—Cross section of Packard fueliser.

Feed Systems.—In early cars the fuel tank was almost invariably located in the front seat, and the fuel was fed by gravity to the carburetter. Later the bodies were constantly lowered, partly to secure greater stability and partly for the sake of appearance, and at the same time the carburetter had to be raised in relation to the engine, owing to the lessened volatility of the fuel. The result was that sometimes when the car had to ascend a steep grade and there was little fuel in the tank there was no head on the fuel, and none would flow to the carburetter. Some of the earlier high-class cars were provided with a pressure fuel feed system, by which gas under pressure, taken through an "adapter" from the engine cylinders, was made use of to force petrol from a tank carried on the frame at the rear to the carburetter. There were two major objections to this system of feed: carbon particles from the engine cylinder often got into the fuel tank (in spite of the gas being passed through a fine-mesh wire-gauze strainer) and thence into the carburetter jet, which sometimes became clogged; besides, every time the fuel tank was filled the compressed gas escaped, and to get an initial flow it was necessary to obtain pressure by a hand air-pump. By placing the fuel tank under the cowl instead of in the front seat, sufficient head for gravity feed was generally obtainable, but the cowl tank usually had an awkward shape and was of rather small capacity.

The solution was found in the vacuum feed system, developed by the Stewart-Warner Speedometer Corp., Chicago, by which (fig. 5) the suction or vacuum in the inlet pipe of the engine was used for transferring the fuel from a rear tank to an auxiliary tank mounted on the forward side of the dashboard, as high as possible. The auxiliary tank had two compartments, upper and lower. Into the upper compartment the fuel was drawn by the vacuum, and it was periodically transferred to the lower by a float valve. Thence it flowed to the carburetter by gravity. There was always sufficent fuel in the carburetter float chamber and in the auxiliary tank to start the engine after the main tank had been refilled.

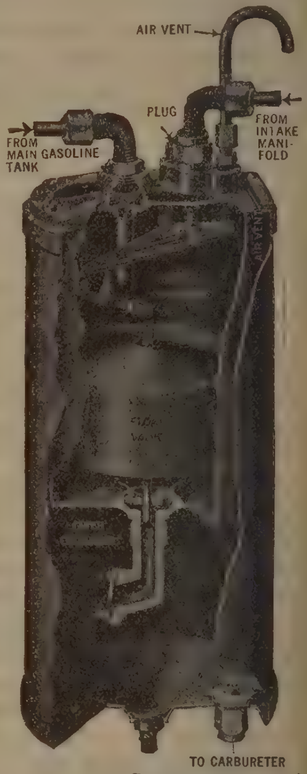

FIG. 5.—Cut-away view of Stewart vacuum tank (fuel feed system).

Ignition.—In 1910 ignition on practically all motor-cars was by high-tension magneto. In 1926 all American passenger cars, with the exception of the Ford (which had a flywheel type of magneto of the maker's own manufacture), had battery ignition. In European countries, on the other hand, although a beginning was made with the replacement of the magneto with the battery and coil system, upon the adoption of electric starting and lighting the movement was soon checked, and in 1925 only 16 out of 133 British models had battery ignition, while in France battery ignition was even less popular and in Germany it was practically non-existent. What led American engineers to change from magneto to battery ignition on passenger cars was the adoption of electric lighting and starting during the period 1912–4. Any car so equipped had an electric generator and a storage battery; consequently there was a constant and plentiful supply of current available, and there was no need for an additional current generator in the form of a magneto. As compared with the early coil and battery systems, the only differences consisted in the use of a plain coil instead of a vibrator coil and of a mechanical interrupter instead of a timer. Sometimes safety devices were provided for automatically opening the circuit or reducing the current flow if the operator should forget to open the switch when the motor stalled.

Use of Thermostats.—No fundamental changes were made in the cooling system, with the exception of the introduction of the thermostat for the control of the circulation. This instrument is connected in the cooling circuit in such a manner that it prevents circulation through the radiator until the jacket water has attained a certain predetermined temperature, generally about 170° Fahrenheit. The result is that in starting from cold the engine reaches normal working temperature in shorter time, and trouble due to incomplete vaporisation of fuel is reduced. The thermostat used, known as the sylphon, consists of a corrugated copper cylinder filled with a liquid which vaporises at the temperature at which the thermostat is to act (fig. 6). An alternate system consisted in the provision of a set of radiator shutters, thermostatically controlled. Many passenger car radiators are fitted with a radiator thermometer in the filler cap, which is a help to the operator in trying to keep his engine running at its best temperature and gives an early indication of incipient overheating.

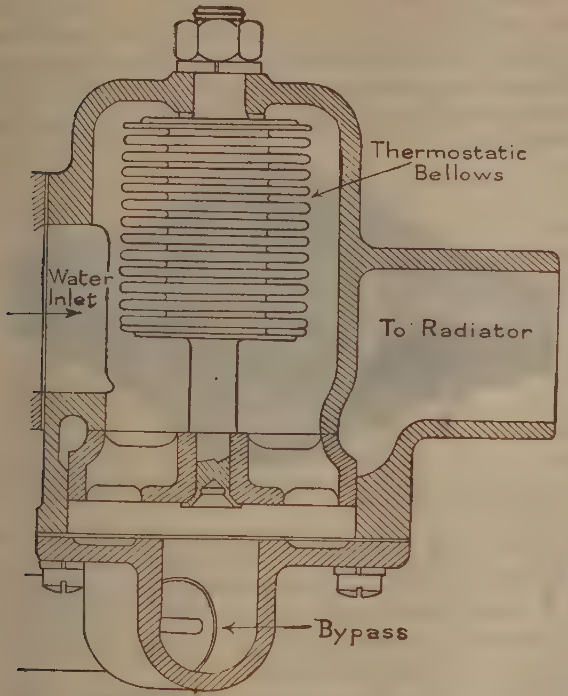

FIG. 6.—Thermostatic valve for control of engine temperature.

Lubrication.—As regards engine lubrication two basic methods came into use, the circulating-splash and the force-feed or "drilled crankshaft" system, as well as combinations of the two. Both systems were employed on early cars, but the force-feed system came into much more extensive use with the development of the high-speed engine. The problem of engine lubrication was rendered much more difficult by the change in the character of the fuel used. A good deal of the fuel entered the cylinder in the unvaporised state, and some of it leaked past the pistons into the crankcase, where it diluted the lubricating oil. In 1920 it was a common experience to find a fresh supply of lubricating oil lose much of its viscosity, and hence of its lubricating value, during the first 100 m. of running. Heating of the crankcase oil also reduces its viscosity, and to reduce this heating many British engines were cast with cooling flanges on the bottom of the oil sump.

Starting and Lighting Gear.—One of the greatest advances in motor car practice was the development of electric starting and lighting systems. The first such system on a car in regular production was on the Cadillac in 1912, and was the design of C. F. Kettering. Electric lighting alone had been used on petrol cars for some years previously, in fact ever since the advent of the tungsten filament bulb. At first the lamps were supplied with current from a storage battery only, which had to be recharged periodically from electric mains; later they were fed with current from a generator and storage-battery installation. The adaption of an electric generator to storage-battery charging on a motor car presented considerable difficulties, for the reason that the petrol motor runs at widely varying speeds, and that the voltage of the generator, therefore, tends to vary within wide limits, whereas a substantially constant voltage is needed for charging.

Many systems of regulation were used with more or less success, but finally the so-called third-brush system was adopted by a majority of the manufacturers of electrical equipment. In this system the generator field was provided with a winding similar to a shunt field winding, but instead of connecting the positive commutator and negative brushes it was connected between one of these brushes and an auxiliary brush, so that only a fraction of the voltage generated in the armature was applied to the field coils. This system of control did not give a constant generator voltage, but with a storage battery connected to the generator it kept both the voltage and the charging current within permissible limits of variation.

In connection with the electric starter the main problem was that of the drive to the engine crankshaft. After trying various devices nearly all manufacturers in the United States and a good many in Europe settled upon the use of the Bendix drive (fig. 7), developed by Vincent Bendix of Chicago. On an extension of the starter armature shaft was loosely mounted a sleeve, which was placed in driving connection with the shaft through a coiled spring. The spring had a coarse, square thread cut on its outside, and on this was mounted the driving pinion, the hub of which was cut with a corresponding female thread. When current was applied to the starting motor, which was always of the series wound type, the armature started to revolve at great speed, carrying along the threaded sleeve on its shaft. Owing to its inertia the pinion lagged behind, and was screwed along the shaft and thus shifted into mesh with a gear-ring on the flywheel rim. Upon abutting against a collar it became fast upon the sleeve, and the starter then cranked the engine, the shock being relieved by the coiled spring.

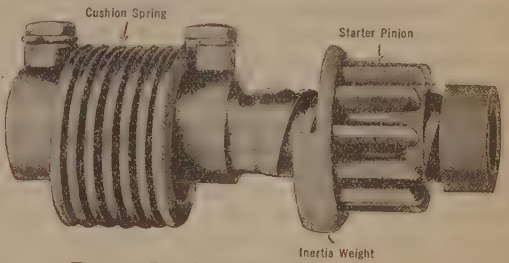

FIG. 7.—Bendix drive for electric starters.

As soon as the engine began to pick up its cycle the flywheel ran ahead of the driving pinion, and the latter was automatically thrown out of mesh by being forced along the screw. Fig. 8,
